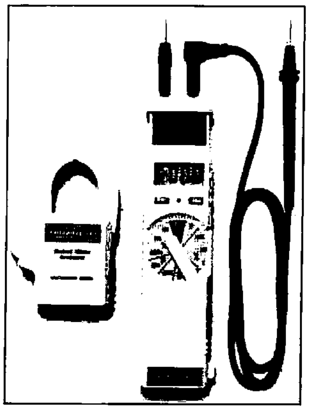
NEW PRODUCTS

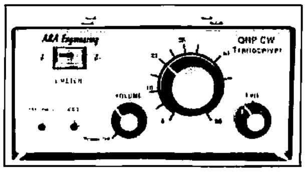
Compiled by Hope Currier



FIELDPIECE INSTRUMENTS

Fieldpiece Instruments has introduced a small (7¼ x 2" x 1") heavy-duty line of multimeters that integrates the functions of a digital multimeter, a voltage checker, and a current clamp meter in a drop-proof, contamination resistant housing. The fully sealed yellow Valox case allows the meter to withstand exposure to contaminants and drops of up to 10 feet. Superior overload protection enables the meters to withstand 1,000 VDC and transients up to 6,000V on any voltage range. Other ranges can withstand 500V. Metal oxide varistors, rather than lower cost spark gaps, are used for transient protection. The two standard "Fluke" style multimeter jacks come out the top to accept test leads, specially designed probe tips, and a specially designed current clamp head. All meters include a continuity beeper, a "Hold" button to lock the display, "Auto-off" to extend the battery life, one red probe tip, one black test lead, an operator's manual, and a rugged clear plastic carrying case. Model HS23 adds the dangerous red LED and beeper and the capacitance function; Model HS25 adds the logic probe.

Suggested list prices range from $79 to $119 for the meters, $24.95 for the Model ACH accessory current clamp head, $3.95 for a pair of standard probe tips, and $4.95 for a pair of insulated extended (2½") probe tips. For prices and more information, contact *Fieldpiece Instruments, Inc., 8322B Artesia Blvd., Buena Park CA 90621; (714) 992-1239 (telephone and FAX).* Or Circle Reader Service No. 201.



A & A ENGINEERING

A & A Engineering has released two new products, 20m and 40m QRP portable transceivers. Features include: single-signal receiver with a narrow CW crystal filter; VFO main and fine tuning, which can be set to cover any 50 kHz of a band; audio derived AGC and two stages of audio filtering for listening comfort, 5 watts output when powered from a +13.8V source; semi-QSK T-R switching with adjustable delay; CW sidetone generator with adjustable delay; and CW sidetone generator with adjustable volume. Weighing only 27 ounces, this transceiver is perfect for backpacking.

The complete kit is priced at $159.95, plus $5 shipping. Contact *A & A Engineering, 2521 W. LaPalma Unit K, Anaheim CA 92801; (714) 952-2114, FAX (714) 952-3280.* Or circle Reader Service No. 202.

CERTIFIED PRODUCTS CORPORATION

The new RED ALERT multi-use meter from Certified Products Corporation will alert users to the sources and intensity of low frequency radiation, suspected of causing cancer, from computers, power lines and other electrical sources. It will locate hidden or buried electrical lines and help prevent accidental encounters by anyone digging holes, tearing out walls, remodeling or working near electrical lines. It is priced at $69.95, plus $2.95 S & H. Contact *Certified Products Corporation, 2816 East 51st Street, Tulsa OK 74105-1704; (918) 743-0269.* Or circle Reader Service No. 203.

NCG

NCG has introduced a new COMET dual-band 2m/70cm base/repeater antenna, the CA-2x4MAX, centered to the American amateur frequencies, 146 MHz/446 MHz. This new antenna incorporates COMET's exclusive SLC (Super Linear Converter) system, which uses parallel elements in order to maintain a stable resonant frequency over the life of the antenna. It also features a new jointing system made of durable ABS plastic to screw the sections together. The CA-2x4MAX is 17'8" long and has a UHF (SO-239) connector. The reported gain figures are 8.5 dB on 2 meters and 11.5 dB on 70cm.

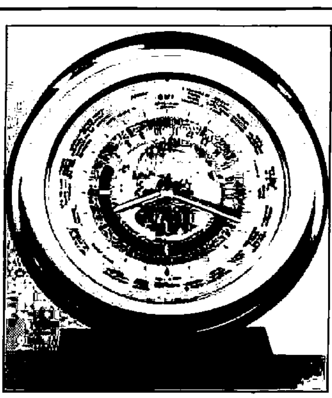
For the price and more information, contact *NCG Company, 1275 N. Grove St., Anaheim CA 92806; (800) 962-2611, (714) 630-4541.* Or circle Reader Service No. 204.

TOWNSEND ELECTRONICS

For those who must use an HT as a mobile rig, Townsend Electronics has introduced the "Rig Saver" universal hand-held/mobile radio mount. You can now safely mount your handheld or small mobile rig where you can see the rig's controls and digital display, and have maximum access to the controls. A vinyl-coated plate protects the rig from scratches while in use. Large knobs make it easy to adjust to any angle for nearly any HT or small mobile. This mount will fit on the console, center hump, engine enclosure or dash of virtually any vehicle.

The "Rig Saver" is available in two models: the Slimline ($24.95) and the Rough-Duty ($29.95). Add $3 S & H; Indiana residents add 5% sales tax. Contact *Townsend Electronics, Box 415, Pierceton IN 46562; (800) 338-1665.* Or circle Reader Service No. 205.

HAM JEWELRY COMPANY



HAM Jewelry is offering an excellent station clock, the World Time Clock. This clock lets users read at a glance not only their own local time but also the time anywhere in the world, without any conversions. The names of 65 cities and countries are displayed around the clock's periphery, and the local hour at those places is read by the adjacent number on the QTR ring. Minutes are read from the minute hand; GMT is read directly from the 12 o'clock position. There is also a polar projection map of the world on the clock's face, showing the world's time zones.

The World Time Clock comes in a brushed goldtone metal case with a bright, polished faceted bezel. It will run for approximately one year on a single "C" cell alkaline battery (not included). The price is $79.95, plus $5 for insured S & H. Contact *HAM Jewelry Company, 26 Edgecomb Road, Binghamton NY 13905; (607) 797-5458.* Or circle Reader Service No. 206.

AMPIRE INC.

Ampire Inc. is offering new and improved model 146, 146OS, and 440 RF switchable mast-mounted preamplifiers for 2m and 70cm, enclosed in extruded aluminum and irradiated to minimize oxidation. The plastic-coated circuit board repels moisture and corrosion. The preamplifiers have been designed to operate from +130°F to −30°F.

For more information and prices, contact *Ampire Inc., 10240 Nathan Lane, Maple Grove MN 55369; (612) 425-7709.* Or circle Reader Service No. 207.

Lasers and Amateur Communications

Does "laser" give you thoughts of some star war device, or just something you would like to experiment with? What can you do with a laser besides drive your neighbors crazy with mysterious spots of red light all over the neighborhood? How about using it as part of an amateur communications system? Many devices now incorporate a laser, which for the amateur means surplus availability, sooner or later. Supermarket checkout scanners are an example of this. Other sources are disc players, printers, and optical scanners. Look for them at swap meets.

What does it take to construct a grass roots laser system? I don't want to get into the fine details on lasers and light frequency relationships, only to give you enough information to get started. If you want more details, there are quite a few good books for the experimenter. One such book is *The Laser Cookbook*, by Gordon McComb. It costs about $18 from Tab Books, and it's well worth the price.

There will be three parts to this topic, the first covering basics and the power system, the second detailing the receiver system, and the third describing high sensitivity receiver modifications using photo-multiplier tubes.

Tube Testing

Surplus, a helium-neon (HeNe) laser with power supply should be less than $100. With only the plasma tube, cost should be quite a bit less. Watch out for used tubes; unless you can test them, you can't be sure they'll work. If they're bad, you can't fix them, unless you are into glass blowing and able to recharge the gas mixture under vacuum conditions.

Plasma tubes (uncased lasers), as well as heads (cased lasers with ballast resistors) have to be tested with a power supply to verify their condition. What happens to old laser tubes? Why will some of them not function? In time, the seals leak; they lose gas, and the helium-neon mixture won't ionize. However, the books I have read all state that the newer tubes have much better seals, and this is not such a problem with them.

An excellent supplier of lasers and laser equipment, both new and surplus, is MWK Industries. They also stock technical books on lasers. Their address is MWK Industries, 1296 W. Pomona, Building 110, Corona California 91720. Tel. (714) 278-0563. I can supply 10 kV 50 mA diodes, which you will need for the power supply, from my local surplus store for $7 for 6 diodes, postpaid U.S.A. I'll also keep a look out for 100 pF capacitors.

System Components

Component parts to gather for a laser communication system include a power supply (high voltage, for the laser), and a 12 VDC muffin fan for the system transmitter. The muffin fan "chops" the laser beam near a 1000 Hz rate; the spinning blades make a tone that can be detected on the system receiver. The receiver needs a large aperture lens, a photosensitive detector, and an audio amplifier to recover the 1000 Hz tone. The audio amplifier in this case is the system receiver. This month I will cover details of the high voltage power supply that you need in order to place a laser (HeNe) into operation.

Safety

Be very careful when working with a laser power supply. Don't be fooled, though it only delivers a few milliamperes at 3 kV, it can be lethal. Put the supply in an enclosure with a good ground system and use a 110 VAC 3-WIRE CORD. Protect yourself from accidental contact with the high voltage.

Also, the PC board you mount the rectifiers and other high voltage components on has to be elevated from the metal enclosure and chassis, and these from each other, to prevent high voltage leakage and accidental contact.

You can make a compact power supply by using a rubber type of potting mix to improve the breakdown insulation resistance. If you do not pot, you can coat some of the components with a Corona dope, a thick paint-on high voltage material that prevents high voltage leakage.

Inside the Tube

A starting pulse of about 10 kV must be impressed across each of two electrodes to ignite the gas in the HeNe tube into a high energy state. Usually 1500 to 3000 volts is needed to maintain this state. After the gas in the tube becomes ionized, it energizes the gas in the capillary tube, which produces a laser beam. Each end of the laser tube has two mirrors, one fully mirrored and the other partially mirrored. At the latter end, the beam exits the tube.

The laser is maintained in this high energy state by a lower power supply voltage of 1.8 to 2.5 kV. The supply must be capable of delivering several milliamperes of current at this voltage. The exact amount of current needed depends on the type and power output in milliwatts of your laser tube. This DC current could vary from about 3 to 7.5 mA for a 10 mW HeNe laser.

The first power supply I built used a 1 kV transformer (AC) with a voltage doubler providing about 2.5 kV to run the laser. I used a strobe transformer to provide the starting pulse. It worked, but was somewhat fussy. I wanted something better.

Our local surplus store had several high voltage ion generator PC boards (incomplete). Located on the board was a series circuit using high voltage capacitors and diodes, forming a voltage quadrupler. Parts were rated at 15 kV. I removed the unnecessary components and attached the quadrupler to the output of my 2.5 kV supply, and multiplied the 2.5 kV power supply output to just over 10 kV. It worked well the first time.

The quadrupler will not sustain high current operation. As soon as the gas is ionized, the tube starts to draw current and sort of disconnects the quadrupler from the circuit, then reverts to the 2.5 kV main power supply voltage. See Figure 1 for the power supply schematic.

Photo. Jack Askew VE4JX and his home-built 20-foot 432 MHz EME dish antenna in Winnipeg, Manitoba, Canada.

The trick to this scheme is that the ion generator capacitors (100 pF) are not capable of much current, but they allow voltage multiplication. As this higher current flows through the quadrupler diodes, which are now just a series network, no multiplication takes place when the laser's current is drawn. See Figure 3 for details of the voltage quadrupler.

Test your power supply unloaded, then test it with a resistive load before you connect it to a laser tube. I use an RCA Senior VoltOhmist with a high voltage (15 kV) probe. I measured the power supply output voltage (starting voltage) unloaded, and it was just over 10 kV. With a resistive load, it dropped to 2.5 kV.

Limiting the Current

The next necessary item for a universal laser power supply is the ballast resistor, the only way to limit current to the laser tube. You have to realize that some power needs to be dissipated. 2.5 kV at a few mA are a couple of watts of power. The resistors must be highvalue, around 100k, in series, and be capable of dissipating the power. In my power supply, I used a large quantity of 100k 2W resistors; I paralleled two of them and made a string of 50k resistors. I put five similar resistors in my output stack. If power supply voltage is lower, near 1.8 kV, less ballast resistors will be required.

When applying power to an unknown laser tube, use as high a value of ballast resistor as you can. It's easier to cut the value of the resistor than to obtain a new tube. Some tubes require a critical value of ballast resistor for proper operation. Laser tubes are all different, even tubes from the same manufacturer.

If a tube "sputters" when power is applied, the ballast resistor must be trimmed. The current is either too great, causing discharges, or too little, causing the current to fold back and the tube to try to re-ignite itself. Sputtering sounds like a ticking inside the tube. Take care when trimming the resistor. *Too much current hastens the death of a laser.*

My 10 mW tube runs with 2.5 kV at 7.5 mA. I have a ballast resistor of 250k, five dual resistor assemblies of two 100k resistors each. Additionally, my laser "head," a tube mounted inside a metal assembly, has an internal 180k ballast resistor. A smaller rated laser, say 2 mW, would require less current. Best operation is when you get good turn-on at lowest tube current with reliable operation. Connect a

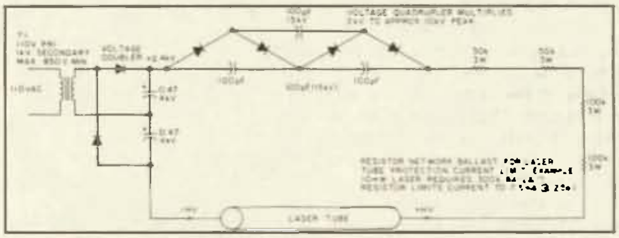

Figure 1. The laser power supply, an AC transformer 850V/1kV secondary. The voltage quadrupler provides the 10kV, low current starting pulse.

Mailbox Comments

Lyle K1HR of Littleton, New Hampshire, is getting ready for Field Day '91. He's building the FET switcher from the August '90 column. Lyle intends to use the switcher to provide AC power for his packet station remote. He'll also use the switcher in the laser power supply, and the 1 kV supply (to be covered in part 3 of this series). As he mentions, the switcher is versatile. Marion Brimberry of Alma, Illinois, writes that he made the FET switcher kit, and it worked great, powering from +12 volts to 110 AC, using the IRFP-140R transistor.

A couple of notes on using the switchers: I found that you can reduce a voltage spike on the FET's drain by placing a series 5 ohm resistor and A 0.1 µF capacitor on each drain to ground. If the spike is high enough (around 100 V), it can puncture and destroy the FET. The resistor-capacitor network helps prevent this. These values are for 60 Hz, and will have to be adjusted for different frequencies.

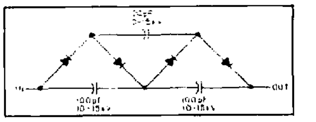

Figure 3. The voltage quadrupler details. All diodes are 8 kV at 130 mA. VARO H-1601-8 (surplus diodes). Capacitors, 100 pF; 50 pF to 200 pF should work OK.

Ross VK2ZRU of Forestville, Australia, working with Alan VK2AXA, used the San Diego Microwave booklet on 10 GHz to construct a small horn antenna and a signal source. He is about to etch a PC board for a 10 GHz transceiver, and is looking for microwave relays (SMA type). Microwave surplus is not plentiful in Australia, and I will try to assist Ross in locating some surplus postage stamp coax relays.

25th Central States VHF Conference

The 25th Central States VHF Conference will be held July 25–28 at the Sheraton Inn in Cedar Rapids, Iowa. It's open to everyone. This year Rod Blocksome K/ØDAS and his staff are planning an excellent series of activities and technical presentations. They're looking for speakers and technical papers. All questions should be directed to Rod Blocksome KØDAS, 690 East View Drive, Robbins, Iowa 52328; (319) 393-8022. Or contact Ron Neyens NØCIH, 8616 C. Ave. Ext., Marion IA 52302-9524; (319) 377-3207.

As always I will be glad to answer questions pertaining to this and other microwave related subjects. Best 73's, Chuck WB6IGP.

For advance tickets mail check and SASE to *R.A.C.K., PO Box 124, Knoxville TN 37901.* For tables and info contact *Steve Fritts WA4GZE, 400 Tobler Ln., Knoxville TN 37919. (615) 525-0801.*

ATHENS, GA The Athens RC will hold its annual Hamfest at VFW Post 2872, Sunset Dr., beginning at 8:30 AM. Admission $3, 15 and under free. Flea Market and Tailgating spaces $2 each. VE Exams. Talk-in on 146.745/-. Contact *Joe Londeree KC4EJY, (404) 353-8196.*

CLEVELAND, TN The Cleveland ARC will sponsor an event at the Bradley County High School from 9 AM-4 PM. VE Exams. Admission $1. Tables $4. Free outdoor tailgating with paid admission. Talk-in on 147.180. Contact *David Evans WD4EZC, (615) 472-1421.*

HERMON, ME The Pine State ARC will sponsor the Bangor Hamfest at Hermon Elementary School from 8 AM-2 PM. Free parking. Admission $2. VE Exams. Talk-in on 146.34/.94. Call *(207) 848-3846* day or night.

TEANECK, NJ Bergen ARA will host an event at Fairleigh Dickinson Univ., from 8 AM-2 PM. Admission: Buyers $2, sellers $8, children free. Free parking. VE Exams from 9 AM-noon, walk-in only. Exams contact: *Pete Adely K2MHP, 13-30 Edward St., Fairlawn NJ 07410. (201) 796-6622.* Talk-in on W2AKR 146.790. General contact: *Jim Joyce K2ZO, 286 Ridgewood Blvd. No., Westwood NJ 07675. (201) 664-6725.*

KITCHENER, ONT. The 17th annual Central Ontario Amateur Radio Flea Market, co-sponsored by The Guelph ARC and the Kitchener-Waterloo ARC, will be held at Bingeman Park from 8 AM-2 PM. Admission $5, children 12 and under free. Vendor tables $8 per 8' space (no outside vendors). Talk-in on KSR-146.37/.97, ZMG-144.61, 145.21; simplex 52/52. Make all checks payable to Central Ontario Amateur Radio Fleamarket, and send to *Fleamarket Chairman, Ray Jennings VE3CZE, 61 Ottawa Crescent, Guelph Ontario N1E 2A8. Phone: (519) 822-8342.*

ALAMOGORDO, NM The Alamogordo ARC will conduct VE Exams at the Alamogordo Mid High School, south entrance, beginning at 12 noon.

JUN 2

MANASSAS, VA The Ole Virginia Hams ARC will sponsor the Manassas Hamfest/Computer Show at the William County Fairgrounds. Open to tailgaters at 7 AM and to the general public at 8 AM. Admission $5, tailgating $5 additional per space. Wheelchair accessible. Talk-in on 146.37/.97 and 223.06/224.66 Commercial vendors contact *Jack KI4VP, (703) 361-5255.* For info call *Jim WD4OJY, (703) 369-3940.*

CHELSEA, MI The Chelsea ARC, Inc., will sponsor the 14th annual Chelsea Swap 'N Shop at the Chelsea Fair Grounds. Wheelchair accessible. Set-up at 6 AM. Donation $3. YL's, XYL's and kids under 12 free. Tables $9 per 8'. Trunk sale, $3 per space. Ladies tables welcome. For info, send SASE to *Robert Schantz, 416 Wilkinson St., Chelsea MI 48118,* or call *(313) 475-1795.*

NEWINGTON, CT The Newington ARL will hold its annual Amateur Radio/Computer Flea Market at the Newington High School from 9 AM-2 PM. Tailgating, weather permitting. Guided tours of ARRL HQ and W1AW. VE Exams by pre-registration only. Register with *Susan Fredrickson WM1B, PO Box 165, Pleasant Valley CT 06063.* General admission $3. Tables $12. For tables and info contact *Les Andrew KA1KRP, c/o NARL, 68 Wildermere Ave., Waterbury CT 06705. (203) 523-0453.* SASE for confirmation.

PRINCETON, IL The Starved Rock Radio Club Hamfest will be held at the Bureau County Fairgrounds beginning at 6 AM. Advance tickets are $4 before May 20th and $5 at the gate. Camping and outdoor Flea Market area is free. 8' indoor tables are $10 each. Talk-in on 146.355/.955. Contact *Bruce Burton KU9A, 1153 Union St., Marseilles IL 61341-1710. (815) 795-2201.*

QUEENS, NY The Hall of Science Hamfest will be held at the New York Hall of Science parking lot. Doors open at 9 AM. Set-up after 7:30 AM. Free parking. Donation for buyers. $4, sellers $6 per space. Talk-in on 445.175 repeater and 146.52 simplex. Contact (at night), *Steve nbaum WB2KDG, (718) 898-5599 or Arnie Schiffman WB2YXB, (718) 343-0172.* (Rain date is June 9th.)

ROME, GA The NW Georgia ARC will celebrate its 60th Anniversary by hosting a big picnic at Floyd College, US 27. All hams invited! Bring one covered dish per family. Fishing and ball games. Talk-in on 146.94.

CONTOOCOOK, NH The annual Spring Flea Market, sponsored by the Contoocook Valley RC, will be held from 8 AM-3 PM. Tailgating. Directions: At Concord NH take I-89 North 14 miles to Exit 7 (Rte 103). East one half mile, on the left. From the West, take Rte 202/9 East to I-89 North, 5 miles to Exit 7, then East. Follow signs for parking. Admission: Sellers $5, buyers $1. Talk-in on 146.895 and 146.94 repeaters, and 52 simplex. Info: *K1OPQ @ pkt WA1WOK-2, or evenings (603) 746-5090.*

BUTLER, PA The Breezeshooters of Western Pennsylvania announce their 37th Annual Hamfest/Computerfest, to be held from 8 AM-4 PM at the Butler Farm Show Grounds. Mobile check-in on 28.495 and 146.520. Directions and Talk-in on 147.96/.36. Fly-in available at Roe Airport. Admission is $1 at the door. Free outdoor Flea Market space. Free parking. Wheelchair accessible. Indoor vendor space is available. Tables are $10 each in advance, on a first come first served basis. Overnight camping, hookups available. VEC Testing by pre-registration only. For info send SASE to *Rey Whanger W3BIS, Box 8, R.D. 2, Cheswick PA 15024, (412) 828-9393.* For reservations and info send check and SASE to *George Artnak N3FXW, 3350 Appel Rd., Bethel Park PA 15102. (412) 833-3395.*

JUN 7

CAMILLUS, NY VE Exams will be held at the Town of Camillus Municipal Bldg. beginning at 7 PM. Test fee for Technician through Extra class is $5.25. Talk-in on 147.300. Please bring two forms of ID and a copy of your license. Contact *John Patchett KB2ERJ, (315) 487-0298.*

JUN 9

LANCASTER, NY The Lancaster ARC will sponsor the Lancaster New York Hamfest at the Elks Club Hall (across from the Lancaster P.O.). Admission $4, includes 8' outdoor Flea Market space. Talk-in on 146.550 simplex or 224.640 repeater. Contact *Chairman Luke Calianno N2GDU, 1105 Ransom Rd., Lancaster NY 14086, (716) 683-8880; Nick WA2CJJ, 5645 Genesee St., Lancaster NY 14086, (716) 681-6410; George Ebert, (716) 894-0343.*

WINFIELD/CENTRAL, PA SVARC, Inc. and Milton ARC will sponsor an event at the Winfield Fireman's Grounds, 60 miles north of Harrisburg on US Route 15. VE Exams. Free parking. Admission $4. Tailgate and table space at $1 per 6'. Talk-In on 145.18/.78 and 146.82/.22. Write to *SVARC, Inc., Box 73, Hummels Wharf PA 17831. (717) 473-7050. Packet KD3KR @ NR3U.*

WILLOW SPRINGS, IL The 34th Annual Hamfest sponsored by the Six Meter Club of Chicago, Inc., will be held at Santa Fe Park. Tickets $3 in advance, $4 at the gate. Large Swapper's Row. Free parking. No overnight parking. Gates open at 6 AM. Talk-in on K9ONA 146.52 or K9ONA repeater 37-97. Get advance tickets from *Mike Corbett K9ENZ, 606 South Fenton Ave., Romeoville IL 60441,* or from any Club member.

ERLANGER, KY The Northern Kentucky ARC will sponsor "HAM-O-RAMA 91" at the Erlanger Kentucky Lions Park beginning at 8 AM. Flea Market set-up at 6 AM. Advance tickets are $4, $5 at the gate, with children under age 13 admitted free. Flea Market spaces are $2 each (tables NOT furnished). Indoor vendor space $15 per table (provided). For info, registration, contact *LC4FET c/o NKARC, PO Box 1062, Covington KY 41012. (606) 341-1213.* Talk-in on 147.855/.255 or 147.975/.375.

GRANITE CITY, IL The Egyptian Radio Club will host the annual EGYPTIANFEST at the club grounds on Chouteau Place Rd. beginning at 6 AM and ending with the main prize drawing about 2 PM. Advance tickets are $1 each or 6/$5; $2 each or 3/$5 at the door. License testing will be at the Sanford Brown Business College, 3237 W. Chain of Rocks Rd. Exam sign-up will be 8 AM-9:45 AM at the hamfest. Saturday night camping is available at the clubgrounds. Talk-in on the ERC-W9AIU 146.76 repeater. Contact *Jim Cleland K9RKU, PO Box 562, Granite City IL 62040. (618) 344-2401.*

NEAR AKRON, OH The Goodyear ARC will sponsor the 24th Annual Hamfest/Family Picnic at Wingfoot Lake Park. Family admission is $4 in advance, $5 at the gate. The Picnic and Flea Market will be from 8 AM-4 PM. Inside tables $6 in advance. Outside Flea Market $3 per vehicle. No overnight parking, no pets, no swimming. For info and advance tickets: *William F. Dunn W8IFM, 4730 Nottingham Lane, Stow OH 44224. (216) 673-8502.*

JUN 14-16

BURBANK, ALBERTA The Central ARL will hold their 19th Annual Picnic at the Burbank Campground, located at the confluence of Blindman and Red Deer River Valleys. Semi-private camp sites available by reservation. Registration starts Fri. afternoon. Camping fees: $15 per family unit, $10 per single unit; $10 for weekend private stall; Sat. evening barbecue/dance; $5, $3 for children under 12. $6 per weekend pass (no camping). Contact *Pat Wight VE6ALD, 886-3883* or look for a message on the *CARL BBS VE6BJH.* Talk-In on VE6UK 147.150+0.600 MHz, or 146.520 MHz simplex.

JUN 15

CORTLAND, NY The Skyline ARC will present the 9th annual Cortland International Hamfest from 7 AM-3 PM at the Cortland County Fairgrounds (breakfast at 6 AM). Outdoor Flea Market space $1. Indoor space available. Advance tickets $3, $4 at the gate, under 14 admitted free. SASE by June 1st to *S.A.R.C., Box 5241, Cortland NY 13045.* Talk-in on 147.825/.225.

CHERRY HILL, NJ The South Jersey Radio Assn., Inc., will host a gala Dinner at the Cherry Hill Inn to celebrate their Diamond Anniversary. An informal gathering will begin at 6 PM with a cash bar, followed by dinner at 7 PM. Tickets are $25 each and you may bring a guest. Arrangements have been made with Cherry Hill Inn for special room rates. For hotel reservations call *(609) 662-7200* and tell them you will be attending the SJRA Dinner on the 15th. The special room rates are $62 single, $65 double; includes use of all hotel facilities and a full breakfast on Sun. morning. For SJRA Dinner tickets, enclose SASE and check/money order ($25 for each ticket) and mail to *Frances Widmann WA2NBE, South Jersey Radio Assn., PO Box 1026, Haddonfield NJ 08033,* before the May 8th deadline.

JUN 15-16

GLENDIVE, MT The Lower Yellowstone AR System will host the 32nd Annual Fathers Day Hamfest Picnic at the Dawson County Fairgrounds. VE Exams Sat. at 1 PM. There will be a hosted breakfast on Sun. Sun. Pot-Luck Dinner at 1 PM. Adult registration $6 each, kids free.

JUN 16

SANTA MARIA, CA The Satellite ARC will hold its annual Santa Maria Radio Swapfest/Barbecue at the Union Oil Company Newlove Picnic Grounds south of Santa Maria, from 9 AM-4 PM. Tables are available at 7 AM for $5. Top Sirloin Barbecue at 1 PM, $8 for adults, $4 for children. Free parking. Talk-in on 146.94. Contact *Esther Miller, PO Box 2067, Orcutt CA 93457-2067. (805) 937-8878.*

CAMBRIDGE, MA TAILGATE Electronics, Computer and Amateur Radio FLEA MARKET, 9 AM-2 PM at Albany and Main St. Sponsored by the MIT Electronics Research Society, the MIT Radio Society, the MIT UHF Repeater Assn. and the Harvard Wireless Club. Admission $1.50. Free off-street parking. Covered tailgate area. Sellers $8 per space at the gate, $5 in advance-includes one admission. Set-up at 7 AM. Mail reservation payments before June 5th to *W1GSL, PO Box 82 MIT BR., Cambridge MA 02139.* Talk-in on 146.52 and 449.725/ 444.725-pl 2A-W1XM repeater.

STEVENS POINT, WI The Central WI Radio Amateurs, Ltd, will hold its 14th annual SWAPFEST at the University Center on the Univ. of Wisconsin-Stevens Point campus. Free parking. Wheelchair accessible. VE Exams. Tables and electricity will be available for commercial vendors. Contact *Art Wysocki N9BCA, CWRA Swapfest Chairman, 3356 April Lane, Stevens Point WI 54481. (715) 344-2984.*

FREDERICK, MD The Frederick ARC will hold its Annual Hamfest at the Frederick County Fairgrounds from 8 AM-4 PM. Admission $4, wives and children free with one paid admission. Tailgaters $5 for each 10' space. Indoor exhibitor tables $10. For info write to *Frederick Hamfest, PO Box 589, Mt. Airy MD 21771.*

JUN 22

COOKEVILLE, TN The Upper Cumberland ARS will host a free Tailgate event at the USDA Bldg., Farmers Market Section on Bunker Hill Rd., from 8 AM-3 PM. Set-up at 7 AM (CST). Talk-in on 145.11/.51. Contact *Ken Roberts, Rt. 4, Box 307, Cookeville TN 38501.*

LEMPSTER, NH The Connecticut Valley FM Assn. will sponsor a Hamfest/Fleamarket from 7 AM-2 PM at the Goshen-Lempster Coop School gym, Route 10 in Lempster. Free parking. Auction. Picnic. Admission $1. Table or space $5 each (plus 1 free admission). Talk-In 146.16/.76. Contact *Conrad Ekstrom WB1GXM, PO Box 1076, Claremont NH 03743-1076. (603) 543-1389.*

SPECIAL EVENT STATIONS

JUN 1

HACIENDA HEIGHTS, CA The Mercury ARA will participate in a community Emergency Preparedness Fair from 1800Z-2300Z. Members will operate using their own call signs. Third party traffic for Fair patrons will be encouraged. Frequencies: 28.3 to 28.5 on 10 meter phone band. For a certificate, send QSL and SASE to *MARA, Attn: WA6BZX, 2751 Montellano, Hacienda Heights CA 91745.*

JUN 1-2

TROY, OH Station W8FW will operate 1400Z-2200Z to commemorate "Strawberry Festival." Frequencies: 25 kHz up from the General 40 meter band and 10 meter Novice band. For certificate, send QSL and SASE to *KS8Z, 1408 Cornish Rd., Troy OH 45373-1212.*

MADISON, OH The Wireless Institute of Northern Ohio (WINO), sponsored by the Lake County ARA, will be on the air Sat. evening between 2330Z-0300Z on 7235 and 21315 kHz, and Sun. from 1500Z-1900Z on 21315 and 28490 kHz, to commemorate Ohio Wine Month. The station call is KO8O. A special 8½ x 11 QSL certificate will be available from *KO8O-WINO Weekend, 10418 Briar Hill, Kirtland OH 44094.* Send a legal sized SASE.

JUN 1-15

HADDONFIELD, NJ The South Jersey Radio Assn. will operate K2AA on all bands June 1-15 to celebrate 75 continuous years devoted to amateur radio. SJRA will offer an attractive QSL marking the event. To confirm contact send a QSL and a SASE to *South Jersey Radio Assn., PO Box 1026, Haddonfield NJ 08033.*

JUN 6-8

MENA, AR The Ouachita ARA will operate KG5QO from 1300Z-2400Z in conjunction with the annual "Lum and Abner Days" honoring Chet Lauck and Norris Goff of early Broadcast Radio fame. Operation will be in the lower 25 kHz of 40, 20, 15 meter General phone bands, and 28.350-400 MHz. For certificate send QSL and 9 x 12 SASE to *Jack Brewer KG5QO, Rt 1, Box 137, Hatfield AR 71945.*

JUN 9-16

AUBURN, WA The Academy ARC will operate K7AC during the week of June 9-16th, to commemorate Auburn's Centennial. Operation will be in the lower 25 kHz of the General bands as well as the 10 meter Novice phone band. There will be an informal net of U.S. Auburns (there are about 22 of them) held on June 16th at 2200 UTC, on 14.240 MHz. QSL via *WA7QCC, 3513 Orchard Place SE, Auburn WA 98002.*

JUN 17-21 & 24-28

JOPLIN, MO The Joplin ARC will operate K5ALU Mon. through Fri. from 2000Z-0200Z, from the Frank Childress Boy Scout Reservation, to encourage youth participation in ham radio. CW-7.050, 14.050; phone-lower 25 kHz of the General 40, 20 and 15 meter bands and the upper 50 kHz of the Novice 10 meter band. For QSL, send QSL, name of operator worked, and SASE to *Joplin ARC, PO Box 2983, Joplin MO 64803.*

JUN 22

LAKE KEYSTONE, OK Lake Keystone OK Masonic Dist. 12 Assn. will operate N5MBD/P from 1300Z-2200Z during the annual State-Wide Masonic Rally on the 10 meter Novice phone band. For certificate, send QSL and large SASE to *Masonic Dist. 12 Assn., PO Box 182, Owasso OK 74055.*

Selectivity and Intermod: What Are They?

A recent letter to the *73* editor complaining about "poor selectivity" when using a Kenwood TH-27A HT with an outdoor antenna prompted me to think about intermod, selectivity and receiver characteristics in general. Let me share some of those thoughts with you.

The reader was picking up paging services and other transmissions which were not on the frequency to which he was tuned. He complained that his new HT suffered from this problem, but his older ICOM IC-2AT did not. Why should newer technology exhibit worse behavior?

The editor explained that such problems are in fact worse with the newer, wideband receiving rigs, and that it was not fair to single Kenwood out. He was quite correct, but the problem goes deeper than could be addressed on the letters page. In fact, the letter writer was not actually experiencing a selectivity problem per se. What he had was front-end overload and intermod. The two are quite different things.

Selectivity refers to the width and shape factor of the receiver's passband. The two are related concepts; the shape factor partly determines the overall width. So, the shape factor is perhaps the more important spec. The term simply refers to how steep the filtering curve appears when graphed on a dB-versus-frequency X-Y plot. If the "skirts" or edges of the response fall rapidly, then the shape factor is steep, meaning that signals outside the defined bandwidth will not be heard. If, however, the skirts fall off in a gentle slope, then the *effective* bandwidth is greater because signals appearing on the skirts will be passed. Obviously, the steeper the skirts, the better.

It is important to note that in today's synthesized receivers, essentially all of the selectivity is obtained in the IF stages. The front ends are usually quite broad. Let me explain.

Two Ways to Go

There are two ways to make a superheterodyne receiver. The old, tried-and-true method was to tune the front end to the desired signal and then greatly increase the selectivity in the IF stages. This system helps avoid interference because the tuned front end rejects signals on distant frequencies, but it requires that the local oscillator and front-end tuning components track each other. In other words, the front end must be resonant on the same frequency as the one which will be passed through the IFs after being mixed with the local oscillator! With a mechanical tuning arrangement, such as a variable capacitor, this is fairly easy to do.

But with a digital synthesizer, it is not as easy. The local oscillator is controlled by a phase locked loop system, driven from a digital reference. It is possible to derive a DC tuning voltage in the process (in fact, one is used to tune the VCO) and control a varactor (voltage-variable capacitor) to track the front end, but it becomes impractical over wide frequency bands. Thus, for many receivers, and especially for those which can cover large out-of-band frequency ranges, designers have turned to another technique.

Open Wide and Say Ahhhh

The obvious way to go is simply to use an untuned front end! After all, you can get all the selectivity you want in the IFs. In fact, most of today's walkies use this technique. The difference between the older units and the newer ones is that the old ones only had to cover four MHz, so there could be a broad bandpass filter ahead of the front-end amp. This very coarse tuned circuit at least kept the out-of-band garbage from getting in. Now that we all expect our pocket rigs to cover a 40 to 60 MHz spread, it just isn't practical. So, there may be no tuning at all.

So what? Why should this affect the operation of the receiver, and why does it matter what kind of antenna you use? Well, as long as the front-end amplifier stays linear, it doesn't. But, when enough signal power (generated by multiple transmitters on various frequencies) gets in, the amp is driven to clipping, just like an audio amp is when you turn the volume up too loud. At this point, the amp becomes a *mixer*. Or, if you prefer, a modulator; it's the same thing. Now, various incoming frequencies can affect each other, just as if they were two inputs to a mixer. This is called intermodulation distortion, or intermod. If the two incoming frequencies happen to add or subtract to or from the one you're tuned to, you will hear one or both of them! Also, if they mix to one of your IF frequencies, some of that resultant signal may leak through the first mixer to the IFs, causing the same effect. And, of course, there can be more than two. Sometimes, three or four signals can mix and cause trouble. Yuck, what a mess!

The reason the antenna matters is because *it delivers tremendously* more signal to the receiver than does the usual rubber duck. This greatly increases the likelihood of overload and intermod. Walkies are most prone to this problem because they are designed to be very sensitive in order to deliver reasonable performance with a poor antenna, which a rubber duck certainly is. The trade-off is that these ultra-sensitive front ends can't take too large a signal level before going into clipping. Also, many of the tuning elements, such as filter coils, which can help avoid intermod are just too darned big for pocket rigs. Many mobiles, however, have them and consequently exhibit fewer intermod problems. Such rigs usually do not have wide, out-of-band coverage.

By the way, the difference between a receiver's lowest discernible signal and its highest level before overloading is called its *dynamic range* and is expressed in dB. Obviously, the bigger the number the better. Ultimately, the dynamic range, selectivity and intermod rejection matter more than does simple sensitivity, especially in FM rigs. There usually is plenty of signal to work with—you just want to keep all the "junk" out of your passband!

Use the Right Rig for the Job

Walkies were never meant to be used with base station antennas, and most don't even perform well with mobile antennas, either. You just can't have it all in one tiny box! If you live in a small town without many radio services, you may have no trouble at all. If, however, you live in Boston, Miami or some other metropolitan area, good luck! I remember using my walkie in the car in Miami with a mobile antenna. It seemed as if my receiver had very poor sensitivity; I was getting into the repeater, but I could barely hear it. Then I tried using the rubber duck and, even inside the metal car, the repeater came in loud and clear. The receiver was being *blocked* by other signals' overloading the front end. Sometimes I could hear them, sometimes I could not.

There are few base station rigs sold anymore. If you are setting up a base, a mobile radio with a power supply makes a better choice than does a walkie.

TX Too?

What about transmitters? Can they suffer from intermod, too? Yes, they sure can! As a matter of fact, repeater operators have that problem quite a bit, because the repeater is often located on top of a hill or tower only a few feet away from other high-powered transmitting devices. But with no "front end," how does a transmitter get intermod?

The mixing occurs right in the transmit final amp! In FM transmitters, the final amp is not linear in the first place. Typically it is a pulse amp, with the pulses being converted to nice clean sine waves by the tank circuit (a resonant coil-cap circuit) and the low-pass filters at the output. The inherent nonlinearity (read "distortion") in these amps makes them ripe for intermod problems, because they are already being driven to clipping by design! So, if enough extraneous signal energy gets to the amps, it will cause mixing and the transmitter will then broadcast the intermod far and wide.

There's an easy way to tell if a repeater's intermod is on its receiver or transmitter: If it is still there after the receiver's squelch has dropped (but before the transmitter shuts down), then it is not coming from the receiver!

It is highly unlikely that you will ever generate your own intermod, even if you use your walkie as a base station, because it takes a substantial amount of unwanted signal energy to get past the transmitter's output filter and into the final amp. Unless you have another big transmitter with its antenna very close to your walkie's, you should be clean.

Are They All the Same?

I've used a fair number of walkies in my day, and I do feel that the "big three" manufacturers have different receiver design concepts. In my opinion (and this is only my opinion—go to a ham club meeting and you'll find people who will disagree), here's how they stack up in general.

ICOMs seem to have the best balance between sensitivity and selectivity, each being a little bit less than the best available separately from the other two, but both being extremely good.

Yaesus have the best selectivity. If you're off 5 kHz, the signal is barely listenable, and if you're 10 kHz away, it is practically gone. However, the rigs are not as sensitive as those from the other two. There have been some exceptions, though, such as the old "Memorizer" mobile rig, which was about the most sensitive 2 meter radio I've ever seen.

Kenwoods have extremely high sensitivity, and it holds up well outside the ham bands. The rigs are not terribly selective, though; it can be hard to tell whether or not you're 5 kHz off.

As far as intermod rejection is concerned, I can't offer any opinion because I haven't used the radios enough under adverse conditions to make a judgment. All I can say is this: No matter who makes them, walkies do not excel in this area. After all, everything has limitations.

Now, let's look at a letter:

Dear Kaboom,

What's the difference between a Class A and a Class B computer? I know it is in regard to the amount of RFI that the computer is allowed to generate, but what does it actually mean? Also, what measures can I take to ensure hash-free computer operation in my shack?

Signed,
Classy

Dear Classy,

Contrary to what one might think, a Class B computer is "cleaner" than a Class A unit. The A designation is for computers to be used in a business environment only. The RFI specs are somewhat looser than those for Class B, which is for home use. It is assumed that homes and apartments will have various susceptible devices, like TV sets, in close proximity to the computer. As long as the machine is in a metal box, most of the RFI will exit via the cables used to connect the keyboard, video monitor, printer, etc. There is no way to be sure you won't get any hash in your shack, but you can do a few things to lessen the severity of the situation. First, use shielded cable for everything you can, including on the computer and the rig. Second, ground the rig well. Third, try to keep the computer as far away as possible. Fourth, wrap computer cables through toroids if you can. Finally, consider going to a laptop if all else fails. These CMOS-based machines put out *far* less hash than the tabletop variety because they operate on much less power to begin with. By the way, some older computers, like my Apple II+, were not even shielded at all. Man, they are serious noise generators. Hmmm, I wonder if I could put a CW key in the micro's reset line and have a wideband QRP rig? Only kidding! 73

W3BE: Radio Amateur of the Year

In case you have not already heard, I am honored—proud—elated—to report that the Dayton Amateur Radio Association has named one of the nation's best known and most respected "amateurs in public service" as the 1991 Radio Amateur of the Year. The person I speak of is someone whom I have been proud to call a friend for the past decade and a half. That ham and friend is John B. Johnston W3BE of Derwood, Maryland, and also of 1919 M Street N.E., Washington DC.

Many of you know W3BE as Johnny Johnston of the FCC, the Commission representative you meet at hamfests and conventions across the nation. His reserved yet knowledgeable approach to discussing matters of regulation has made John a friend to many of us, and a man who is respected by all.

Johnston was nominated by a coalition of amateurs from across the country. They felt that his two decades of dedication to the regulatory needs of the nation's amateurs deserved major recognition. In their letter of nomination, they cited John's almost single-handed re-write and reorganizaton of the Part 97 amateur rules as one of his major contributions. They noted that this was not a task assigned to him by his superiors in the Commission, but rather done at his own initiative. He used his unparalleled knowledge of the amateur service rules to address the problems that their ambiguities were causing to the amateur service. It was also noted that in his position as Chief of the FCC's Personal Radio Branch, he has always made himself available to help members of the amateur community to find solutions to their problems, while also working to ensure an appreciation of amateur radio within the structure of the FCC.

We have heard more than one person say that honoring W3BE for his years of service to the United States Amateur Radio Service is long overdue. John has become almost inseparable from the service regulations that his hand and mind helped create. Apparently, the D.A.R.A. Awards Committee heard the same call to honor him and his work. It is my opinion that John B. Johnston W3BE is the best friend we amateurs have in the ranks of the FCC.

220 Gone

John Johnston W3BE being named Radio Amateur of the Year was the good news this spring. Now here is the bad. John's superiors at the FCC—the Commissioners—say that hams will have to be off of the 220 to 222 MHz band by midsummer. While no exact date can be given, amateurs will have to vacate the band entirely 90 days after the effective date of the rules change, adopted on Thursday, March 14, that takes hams off the lower part of the 1-1/4 meter band and puts commercial services on. The NPRM was adopted pretty much as proposed, with the addition of a reserve of some channels for public safety use. Automatic vehicle monitoring will probably be available through the entire band.

The FCC rejected the ARRL's request for secondary access to 220–222 MHz. The American Red Cross lost in its request for special frequencies, as did Electronic Tracking Systems, Inc., for police tracking units. And regarding PELTS, the Personal Emergency Locator Transmitter System, no decision was made. *[For more information on PELTS, see the Nov. '90 "Homing In" column.]* Some hams say they won't leave the band. They believe that the FCC won't enforce the new rules. If these hams insist on staying, they may have to put their licenses, wallets, and possibly their personal freedom on the line. Isn't it time to let the matter stand? It was a good fight, but we lost!

13cm Offered to Business

Mind you, I am writing this column on April 1. I wish i could say, "April Fools!" but alas, I can't. And, as if the loss of 220-222 MHz was not a bad enough way to enter the spring season, now the 13cm amateur band appears to be up for grabs. In fact, it may be given away by the FCC at next year's World Administrative Radio Conference (WARC '92). The Commission is proposing that it be turned over to commercial use for digital audio broadcasting and satellite uplinks for worldwide mobile services.

Specifically, the FCC suggests that 2360–2410 MHz—including the 2360–2390 MHz slice of spectrum now off-limits to amateurs—be given to the satellite-based Digital Audio Service, and 2410-2450 MHz become an uplink band for mobile satellite services. This would leave hams with only 2300–2310 MHz, and this only on a secondary, totally noninterfering basis to any and all other users who might receive assignment at a later date. The FCC also proposes that hams be granted some limited, noninterfereing access to the entire band. The key word appears to be "noninterfereing," which could mean anything to anybody, since no designator for what constitutes "interference" has ever been determined for blanket application across the entire electromagnetic spectrum.

The proposal to reallocate 13cm is a part of the overall United State's position paper for next year's World Administrative Radio Conference. It should be noted that most countries in the world, especially the emerging third world countries, are already set against the Amateur Radio Service retaining its 20 and 40 meter bands. The FCC's offering the 13cm band up for grabs only strengthens the position of those seeking to gut amateur operations in all spectrum from DC to light.

Michigan—"Privating Out" OK

Let's close with these two items about FM and repeaters. Ever hear the term "privating out"? In the world of FM and repeaters, it means that a repeater owner has decided that he no longer wants the general amateur community to have access to his machine. So, he puts the word out that, as of a specified date, the repeater will only be available to selected users of his choice. In effect, he has evicted the overall amateur community. He has taken an "open" repeater and has "privated out."

Michigan has a long tradition of opposing any closed or private repeater operation. Now it will not only permit the establishment of closed and private repeaters, it will also permit existing systems to go private if they so choose. The Michigan Area Repeater Council made this new stand public in its February newsletter.

The question of whether or not to permit private repeater operation in this state came to a head several months ago. As noted, Michigan traditionally banned closed and private systems. Then, last fall several repeater trustees informed the council that they were changing to closed operation. Another refused to give the council some key system access information for its records. They decided it was time to discuss the privating-out issue.

In the discussion, which took place last December 1990, the Michigan Area Repeater Council determined that the issue of private versus open operation is strictly the province of the repeater owner, and not the business of the coordinating body.

However, the council also demanded that no matter which type of operation a repeater owner chooses, he must supply all data needed for the coordination body's technical database. The lack of this information, the Michigan Area Repeater Council says, will seriously detract from that organization's ability to coordinate spectrum usage.

The Big MACC

We can at least end with a story that reads like an April fool's joke, even though every word is true. Can you believe that a hungry "Big MACC" has eaten two more states? In this case, the Big MACC we are talking about is the giant Mid America Coordination Council.

Late word is that the Big MACC has become even larger, bringing Ohio and Indiana under its umbrella. This makes 13 the total number of states represented by the MACC. It also makes the Big MACC the largest coordination council in the United States, and the largest political representative of FM and repeater interests in the world. In matters of repeater coordination policy, it is probably more politically powerful than the ARRL!

UPDATES

ROBO-COPy

See the above article in the Oct. '90 issue, page 28. *Important: See also the update in the Dec. '90 issue.* Mike Hansen WB9DYI, the author, has sent us the latest revision of ROBO-COPy, version 3. They are currently listed on the 73 BBS (in the 73Mag SIG) at (603) 525–4438. The file named robo31.exe is for COM1, and the file named robo32.exe is for COM2.

WB9DYI: "ROBO-COPy version 3 uses the RI input of the COM port, and is thus completely compatible with the interface circuitry of the robo2.exe. (The correct pin number for RI on the DB-25 connector is 22.)

"Version 3 is different from version 2 in two areas:

"1. A fix was installed in the routine that prevents the average from being skewed by a large number of repetitive dits or dahs.

"2. A correction factor was added into the the word-per-minute calculation to compensate for the different sampling filter settings. This yields more accurate wpm readings at the HI filter setting. Note that the wpm calculation is based strictly on the speed of the incoming dits and dahs, and does not actually count the number of "words" sent over a 60-second period, like an FCC code exam. On-the-air tests using W1AW show the new algorithm to be accurate to plus or minus 3 wpm.

"*Note:* Early models of the Tandy 1000 series of PCs do not have truly compatible COM port BIOS routines. They lock up when attempting to run ROBO-COPy.

"Well over 100 hams have contacted me about ROBO-COPy. I appreciate any feedback or recommendations. Please contact me via the 73 BBS under 'mch" or by mail at 1405 Tangle Wood Dr., Algonquin IL 60102."

QRP

Low Power Operation

Mike Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

Field Day Success

With the June flowers, comes Field Day: both a contest and an emergency communication exercise many hams enjoy. Plans for a winning Field Day are developed all year long. The average QRPer can make a good showing when operating Field Day, and have a lot of fun to boot!

There are two things you must have to complete a successful Field Day operation: power and antennas. Last year I operated the full 24 hours of Field Day with a 6 amp/hour gel cell battery. A small Arco GP100 solar panel kept the battery charged. There was no need to have a charge controller connected to the battery, as a constant load was maintained by the Argonaut. The primary mode was CW, with a dash of SSB thrown in. While I didn't generate an earth-shaking score, I worked just about everyone I could hear.

The Expanded Voltmeter

I brought along with me a simple and very handy piece of test equipment: an expanded voltmeter. A dedicated state-of-charge meter for lead-acid and NiCd batteries can be built very easily with four basic components: a zener diode, a resistor, a potentiometer, and a 0–1 mA meter. This hand-held voltmeter will allow you to keep track of battery voltage without guessing. Of course, you could use one of the many inexpensive digital meters on the market, but this device is simple and costs very little to build. If you step on it and break it, you're not out a lot of money.

Here's how it works. The voltage across the zener diode is essentially constant with respect to the current passing through the zener. If the battery voltage moves around, which it will (that's why we are doing this in the first place), the zener voltage will remain fixed at 10 VDC. The design concept is to use a meter to measure the difference between the fixed zener voltage and the battery's positive terminal.

Because the really important voltages are between 10 and 15 VDC, that's what we'll measure. Since a fully charged lead-acid battery is nearly 15 VDC (in most cases, the voltage of a fully charged gel cell battery is 14.4 volts under charge) the meter will then need to cover a range of 0–5 volts, since we are referencing against the zener diode voltage.

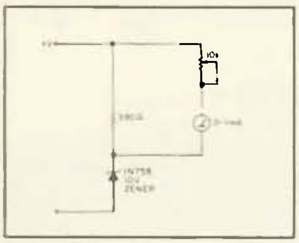

Figure. Make an expanded voltmeter for Field Day

Easy to Build

Construction is, by design, simple. Only four components are needed. You'll need a 0–1 mA meter, a zener diode, a resistor, and a trimmer pot. Check the parts list on the schematic. A suitable meter is available from Radio Shack. The meter, as it comes from the package, is a basic 0–1 mA meter.

Remember, you *don't* have to use the meter from Radio Shack. Any 0–1 mA meter will work. I've used 0–50 microammeters and they've worked fine. I've even used old surplus 270 deg meters without trouble. Use what you have! If you want to use the Radio Shack meter, its catalog number is RS 270-1754.

In fact, you can get all the parts needed for this project from Radio Shack, with the exception of the 10 volt zener diode. I have a stock of these here in my junk box. If you can't find the zener diode called for, drop me a letter. I'll send one off to you for the price of two first class postage stamps. One for the diode, the other for the return postage.

Conversion of the meter is a simple matter of adding the extra components to a small piece of perf-board and changing the face of the meter. Since the meter's face already says "DC Volts," all we have to do is change the scale. You'll need a pair of steady hands, some small screwdrivers, and a dab of White Out™. A sheet of press-on letters will be needed to re-mark the meter's face. Of course, you could always re-mark the meter's face with a pencil or pen, too.

Place a soft cloth on your work area to prevent the meter's clear plastic face from being scratched. To remove the plastic face, hold the bottom of the meter in one hand, and pop the face off with the other hand. You'll find two parts to the meter's plastic face, the face itself and the black shield. Lay these aside.

Notice the two Phillips screws holding the scale to the body. With a small jeweler's screwdriver, carefully remove one screw. Be sure you don't drop the screw into the meter's hair spring or moving coil. Remove the other screw. Now, don't lift the metal scale off; rather, *slide* it off. Replace the two plastic parts and set the meter aside. This will protect the fragile needle and hair spring.

Lay the meter face down on a hard surface. You don't want to bend the metal plate. Since one end of the meter's scale is already marked 15 volts, you only have to change the zero at the other end to a 10. Use the White Out and cover the unneeded scale numbers. After the White Out has dried, use a press-on number to re-mark the scale, from 10 volts where the zero used to be, to 15 volts on the high end. The middle of the scale is 12.5 volts.

Photo A. The completed, expanded voltmeter keeps an eye on the battery.

As a thought, some colored highlighters could be used to mark the scale in yellow, red, and green. If you don't want to go to all this trouble, use a pencil and remark the scale by hand. The first method is much more professional looking, though. Reassemble the meter and put it aside for mounting in an appropriate cabinet. A Radio Shack plastic project box works quite well. I used a Radio Shack #270-233.

The actual circuit may be assembled on perf-board or a simple PC board. Hard wiring may also be used. I assembled the circuit and used a piece of double-sided tape to hold the board to the inside of the plastic box holding the meter. Several feet of test lead wire and clip leads finish up the construction. A rubber grommet protects the wires from chaffing on the plastic box.

Calibration

To calibrate the meter, you'll need a variable power supply and a digital voltmeter. Using the digital voltmeter, set the power supply to read 15 volts, and adjust the 10k trimmer for a reading of 15 volts on the expanded meter. Change the voltage to 12.5 volts and note the reading. It should be in the middle of the scale. That's all there is to it.

Because of the tolerance of the analog meter and the zener diode, the expanded voltmeter may not track 100 percent with the digital voltmeter. Since we're interested in the range from 12 to 14 volts, adjust the trimmer for the most accurate reading between these two points. The expanded voltmeter will be accurate to within 0.1 volt. Button everything up and start using your expanded voltmeter.

Just one word of caution when using the meter: Don't measure the voltage at the load unless that is where you want to see the real voltage to the device. If you connect the voltmeter to the load, you'll see the voltage drop from the battery to the load.

The best place to put the voltmeter is right at the battery, not the load. You can use this to your advantage, however. If you measure 12.5 volts at the battery, and then only 11 at the load, you've got some serious trouble in your power connections. An easy fix is increasing the wire size between the load and the battery.

By using this expanded voltmeter on your battery-powered equipment, you'll always know their condition. This may keep your signals from chirping away on CW or FMing on SSB. You don't want to be known for a nasty signal in this year's Field Day.

The expanded voltmeter will be a welcome addition to your Field Day's war chest, right beside your death ray antenna. 73

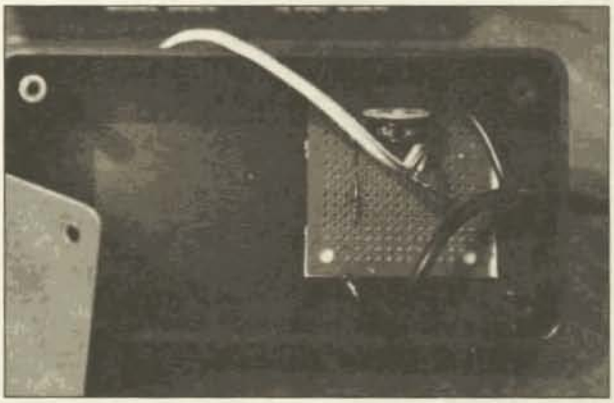

Photo B. Inside the expanded voltmeter: Only three components needed!

Never Say Die

Continued from page 4

want to spring for the 12-second 4.5 kHz passband chips. Just what you need to make that 2" speaker sound good when you talk with someone.

If your message is longer than 20 seconds the chips work just fine in series. Talk as long as you like.

These are being made by Information Storage Devices of San Jose and samples are already being shipped. (See the "New Products" section of *73*, May 1991.)

Just think of how much time you'll save by being able to read *73* while in a QSO and only having to speak the other chap's call and name one time! Or play Nintendo, watch a ball game on TV, or whatever you do to fritter away your life.

What about the other chap's transmissions? Don't you have to waste time listening to them? Nah, just program in a cheery, "Okay on everything OM," and forget it. He's probably using a QSO machine too, right?

Think of how much aggravation you can save during contests by using one chip to call, "CQ contest" and another to give your contest number, automatically incremented. Chip 1: "XZ2AB." Chip 2: "This is W2NSD portable 1 in New Hampshire. QSL. Your number is five nine." Chip 3: "One six seven" (this one increments to give the three numbers in sequence). Back to chip 2: "Is that a roger?"

A sharp contest operator should be able to keep at least two rigs going simultaneously, one on each end of the band, thus doubling his score. I'd arrange for a cassette recording of all contacts so I wouldn't even have to log the received contest numbers until later.

Let's get cracking on some QSO machine designs. The winners will get their circuits published in *73* and probably find ten new companies (and five old ones) offering royalties to manufacture their invention. Put me down for 10% of your royalty or I'll sue.

Now, for those of you whose sense of humor rotted off years ago or was destroyed during puberty, while the chips are real and the applications will work, I'm not serious about suggesting totally automatic contacts.

For those of you who think I surely must be kidding, just wait until you see some QSO machine articles. And for those of you who are confused and aren't sure whether I'm serious or not, well, golly, me either. Now get started chipping away so I can fill my log and write editorials at the same time.

You can call Jim Oliphant N6OBM at (800) 825-4473 for more info on the ISD chips. Tell him Wayne sent you.

Crowded Two

I have a message for you to pass along, if you will. If you dare! I happen to think you are too chicken to speak up. Well, I'm not.

The next time you hear some old addle-brained idiot grousing that the no-coders shouldn't be allowed on two meters because the band is already crowded enough, please break in and tell him that Wayne has a message for him: He's a foolish fossil and should apply immediately for his Silent Key certificate for the brain-dead.

Two meters crowded? In what universe is that? Sure, maybe in Tokyo, where they have about five times as many hams as we do. Don't tell me about crowding; I get around too much and I listen. In the last year I have called in on every repeater I could reach while visiting Los Angeles, Denver, Las Vegas, Chicago, New York, Dallas, Nashville, Minneapolis, Boston, Kansas City, Dayton, Columbus, Mobile, New Orleans, San Diego, Portland (ME), Troy (NY), and a few more cities. Oh, I've made a few QSOs, but 99% of the time all I get is a kerchunk and silence. Not only are the repeaters not in use, no one is even listening to them.

Oh sure, every repeater channel is occupied. I can often raise a dozen or more repeaters. There just isn't anyone listening to them. So tell me all about how crowded two meters is and I'll tell you you're full of . . . er . . . baloney. From what I've experienced in every part of the country we could handle ten times as much activity on 2m without causing any problems.

I realize there's no way to get through the ceramic minds involved. They've never let facts or reason even remotely influence their strongly held, frequently expressed beliefs. These tend to be the same fuddy-duddies we hear sounding off about Jews, blacks, Japs, homos, wetbacks and so on.

There's nothing new about hatred and intolerance. Alas, I don't see any signs of the human race improving in this respect. No learning curve here. We see groups all around the world anxious to kill other groups for religious, racial or tribal reasons.

Unless you're married to them, you generally have to not know someone in order to hate them enough to want to kill them. Communications can make a big difference . . . even in marriage, where it's rarer even than on 2m.

Amateur radio is about the only medium where people can talk with people in other countries. Even tourists rarely get to talk to more than hotel employees or waiters. We have an enormous tool for helping the world to change, but we've been trashing it with idiocies such as the DXCC award.

We also have 125,000 Techs self-imprisoned up on 2m, where they can't talk much further than they can see. The world will get no help from them. It's a pity that in a time when people-to-people communications are so desperately needed, that so many of us are handcuffed to the VHF bands, imprisoned mainly by a terror of the code.

I've tried to push Techs to get their General licenses before. A few have reacted intelligently, but many have gotten angry. That damned Wayne Green! It's this sort of reaction which has probably prevented any other ham rags from even trying to write about such a delicate subject.

So okay, get mad at me, if that makes you feel any better. But the worst part of that is that you know I'm right. Your only out is to get even madder. Your alternative is to admit that, yes, I'm right and you have been taking the easy way out. Yes, it takes some work to get a higher license. Is work really that awful?

Techs and Novices, we need you down there on 15m and 20m. We need you there badly. The chaps who are there have made such a mess of those bands that they're like inner city slums. You're going to be absolutely disgusted when you hear how bad it is. You'll hear Extra Class hams chasing DX hams off the air any time they surface. You'll hear these roving gangs of terrorists assaulting rare DX with merciless pile-ups until they are battered and bruised and give up.

They don't have the slightest interest in talking with the chap in some rare country. All they want is a QSL card and they don't care what it takes to get it. I'm old enough to remember when "green QSLs" were dollar bills. Now they're $20 bills.

A few DX hams have gotten addicted to our green QSLs and it keeps 'em going, despite the treatment they get. If the value of the dollar keeps dropping, they're going to start demanding pictures of Grant's tomb instead of the Bush homestead.

QSL of the Month To enter your QSL, mail it in an envelope to *73*, WGE Center, Forest Road, Hancock, NH 03449. Attn: QSL of the Month. Winners receive a one-year Subscription (or extension) to *73*. Entries not in envelopes cannot be accepted.

We desperately need you Techs down there to introduce a whole new concept to amateur radio: actually talking with people in other countries. Making friends . . . not just for yourself, but for America too.

There's a destructive phenomenon that takes place when two groups (or even people, like husbands and wives) are not in good communication with each other. I've never seen anyone else write about this, but I've seen it in action and it's a corker.

When communication is limited between two groups, what communication there is tends to get blown all out of proportion. Paranoia sets in.

Techs, we need you to get off 2m, at least part of the time, and start talking with hams in France, Germany, Hungary, Estonia and so on. We need to let them know that we're interested in them . . . in what they do, what interests they have, what problems, what successes. Have they any questions about what America is really like? What's their perspective on the EC? What do they think about Bush, Gorby and Saddam? What ethnic problems do they have to cope with?

Look around for some African stations and start finding out how it is to live in Kenya these days. Uganda. Have you ever actually talked with a South African about what's going on down there? You'll find a completely different perspective from anything you've read in the papers or heard on PBS, I guarantee.

We need you to get down on our DX bands and start cleaning 'em up. Don't succumb to the DXing craze. Let's get together and force *QST* to isolate the DXers' band pollution they foment just to DX contests.

Now, am I bad-writing the League? If you call a constructive plan to help our hobby and our country bad, I suppose so. Let's see some Techs with guts getting their local clubs to start General study classes and moving cleanup squads into 20m. It wouldn't hurt to start at the top of 20m and clean up the awful messes on 14.313 and 14.275. Then get up some steam and charge down the band, leveling those rotten pile-ups as you go. Take no prisoners.

. . . de **W2NSD/1**

Golly, I almost missed our sked. I was busy sending some comments to the Candy Company on a recent petition intended to help solve the packet brouhaha. You know, where some idiot put a message into a packet system asking people to call a 900-number about some sort of stopping the war political baloney.

Sure enough, some ham got a wild hair and complained to the FCC, an action which should be punishable by death or worse, and the next thing you know official harassment was the order of the day. The foolish ham who started the chain reaction with his dumb message brought all the innocent relayers

whose stations automatically passed along the packet into the soup.

What should have happened is that when someone noticed the dumb message they should have let the originator know what they thought ol him screwing up like that. When we ask the FCC to solve problems for us they almost invariably do it with an atom bomb, leaving us in shock and having to fight the fallout for years afterward.

Anyway, in case you're interested in my comments, here's what I wrote. If not, pour yourself a cuppa coffee and skip it.

Tom Blackwell N5GAR and Joe Jarrett K5FOG petitioned the FCC to put the responsibility for an "illegal" message on the originator.

Secretary FCC
Washington DC 20554

Re: RM-7649—Amending the repeater rules

Yo, Commissioners:

The amateur radio service can benefit our country only if it is permitted to develop new technologies with a minimum of interference. Indeed, amateur radio can be an enormously valuable resource.

It's well known that most scientific breakthroughs have been made by amateurs. Professionals normally can't afford to spend the time and money it takes to pursue technologies that have only a slight chance at success. Amateurs can. Most fail, but the few who succeed are worth all the failures and more.

Radio amateurs developed most of our present communications modes. Jack Babkes W2GDG developed and pioneered narrowband FM back in 1946. That's the primary communications mode for mobile VHF and UHF today. I was one of his helpers in this project.

The first practical single sideband communications system was developed and pioneered by an amateur (Don Noregaard)...as was slow-scan TV (Copthorne McDonald). W8JK invented the helical antenna. W1FZJ invented the practical parametric amplifier (on 6m) and I published the first articles on this discovery in 73.

Today's cellular telephone system would be unlikely if the technology hadn't been developed by amateurs in Chicago. I published the circuits for this system almost 20 years ago. Amateurs were the driving force that got microcomputers going. Today amateurs are developing packet communications systems. They need all the latitude possible to develop and pioneer this new system.

When the FCC formed the Long Range Planning Committee (LRPC), the group quickly decided that the only *dependable emergency communications system we have in America is amateur radio. Since the high speed automatic relaying feature ol packet radio is a key element in building emergency networks, the current FCC decision to block this is harmful to both the development of packet technology and to the long range interests of America. I was a member of the LRPC from its founding.*

The rule change proposed in RM-7649 provides a simple solution to the problem that the FCC has caused. I recommend it be accepted until even less restrictive rules can be devised.

Amateur radio needs less rules and more latitude, not federal harassment. Technology is the key to the future, so the FCC should be working with the amateur radio industry to devise ways to increase the number of youngsters attracted to the hobby, not closing off experimental areas from development.

Sincerely, Wayne Green W2NSD/1

Naturally the Commissioners didn't allow enough time (a crummy 30 days from March 6th) for us to get the word out and get enough comments on this sore subject to have some weight.

Some Progress

The big problem we have in amateur radio today isn't the new no-code Techs, it's the old-timers who have their heels dug in and are fighting progress. The new Techs are getting high marks from every corner.

While I want to thank the many readers who've been crediting me with getting the no-code license accepted, I don't feel that a 33-year fight finally won is much to crow about. If we'd gone this route 30 years ago when I started pushing for it, I believe we could well have five million hams today instead of under a half million and that the U.S. might still have a consumer electronics industry.

I've recently been talking with some of the microcomputer pioneers. If you've got some old issues of *Microcomputing* or *80 Micro*, you can look back and see where, if Radio Shack had followed my urging, the whole world today might well be TRS-DOS instead of MS-DOS, and Radio Shack would probably be around $50 billion ahead of where they are now.

If Texas Instruments had paid attention, instead of dropping $635 million on their TI-44/A computer, they could have parlayed it into a $10 billion a year new business.

So many might-have-beens! With Sony now looking to acquire Apple, if only Jobs hadn't beaten Wozniak with his Lisa vs. Apple II battle we'd be way ahead of the present 80486 technology...and Jobs would be on top instead ol a loser with his NeXT...and the Woz back teaching for a living.

Sigh, back to the present, our next goal is to not just welcome our new Techs, but to get hundreds of thousands of 'em in and on the ladder to General. If you hear any old-timers grousing, throw a pail of ice water on 'em and get 'em to cool that crapola. Tell 'em to get an enema and get aboard the world of the '90s.

We need to bring in a few million young hams. We need to get cracking on narrowband technologies. We need to go digital. There's plenty to do to clean up the mess we've made. We need less baloney on the bands. We need to get rid of pile-ups and other such intentional interference. We need several thousand new ham clubs. We need to encourage every active ham to spend at least an hour a week learning more about technology. Clubs can help here. Tech sessions over repeaters will help. Our new *Radio Fun* should help a lot.

We're beginning to make some progress. The VEC system I began pushing over 20 years ago got accepted and is working well. Ditto the repeater regs I urged almost 20 years ago. These were all fought tooth and nail by the ARRL, as were the RTTY regs I started pushing in 1951 with my first publication, *Amateur Radio Frontiers*. The League finally lost, as they always do, but only after having wasted years of our time.

Never mind my grousing about the League and their eternal politics. Their eye is on the money and that means the millions they make from ads in *QST*. My goals have always been to get things done...but not to lose enough money in the process to put me out of business.

I'm having fun today with my new recording studio. I'm working on some poetry CDs, some children's books on CD, promoting prerecorded DAT tapes, independent label distribution, and at least a half dozen new publications.

When I was young I loved to read the *Oz* books and the Ernest Thompson Seton wildlife books. I don't know if kids today will enjoy them as much as I did, but I'm going to read 'em and put 'em on CDs and see what can be done. And there's a bunch of fantastic poems by an old friend of mine that should be read and put out on CDs too.

I'm disappointed that in my 40 years of publishing ham magazines I haven't come across anyone who's been able to capture the excitement of our hobby in poetry. I guess we're too left brained to be artistic, eh? Yet we have Jean Shepherd K2ORS and his marvelous stories, so we're not all nuts, bolts and ICs.

Is there anything in our rules which says that our QSOs have to be boring and repetitious? I know our regs pretty well and I don't recall anything that prohibits us from being entertaining during a contact.

How many contacts have you had where someone read you a story or a poem? Has anyone even read you an interesting article? Even out of a ham magazine? Maybe we can break our 70-year-old pattern and start a new generation of hams who use our magical medium to actually communicate. Sigh, I suppose that's too much of a change to ask. Perhaps, in 30 years, if we've still got any frequencies, and long after I'm gone, perhaps we'll have a generation of amateurs who finally understand the concept of communications.

Exchanging trivia...even less than one would get at a cocktail party... isn't communicating. Sure, it's difficult to get into a deep conversation with someone you've never talked with before. But you're doing it with hams you've been talking with for years.

I'm finally beginning to get letters telling me about the most exciting times some of you have had in amateur radio. Great stuff! I'd love to hear from more of you. I really don't care what rig or antenna you're using as long as I can hear you. I want to talk with *you*! I want to know what you particularly enjoy about amateur radio. I want to know what other things you enjoy, if there are any. Heck, even if you enjoy sitting down to watch *The Simpsons* with a brew, at least you'll be telling me about yourself. Yes, I enjoy *The Simpsons*. It comes in on channel 25 here, so I finally gave up and got an antenna splitter so I could record the high channels. Recording programs makes it so I don't have to go to the fridge during commercials...part of my weight maintenance plan.

I love *Roseanne*, *Murphy Brown* and *Hunter*. *Law & Order* is usually good. *60 Minutes* is usually worth checking out, but my fast-forward button gets used a lot when they stretch things too much. So why is Wayne writing all this garbage? To give you some idea of things you can talk about. TV shows, movies, music or books, magazine articles...all are fodder.

I hadn't realized how much our welfare program was responsible for the mess in our inner cities...the single parent families...the teenage pregnancies...the crime and drugs. Once I read about it, it all made sense. If you'd contacted me after I read that you'd have gotten an earful.

If you're from around San Diego I'd ask if you know about the organ concerts every Sunday at 2–3 p.m. in Balboa Park. I've got a nice DAT of a concert sent by a reader. And I'd undoubtedly be able to work in a brag about being at the helm of a nuclear sub last year. Hey, when we have some coups we don't keep 'em too carefully hidden.

Now get down there on 2m and start talking with our new no-code Techs and get 'em on the right track. See if you can get 'em to try 6m too. And some Oscar contacts. And packet. Tell 'em how much fun you've been having with these.

Tell 'em how much fun you had going on a DXpedition to a Caribbean Island. Explain how little it cost and how big the pile-ups were. Tell 'em how it felt to be king of the hill for a change.Or did you pop up to St. Pierre? That's close and inexpensive to visit...and you couldn't find a more friendly people to visit.

Maybe you haven't DXpeditioned yet, but at least encourage the new Techs not to pass up this incredible part of our hobby. Explain that the code is simple when they use Uncle Wayne's system, so not to let that keep them away from the fun of talking with DX or even being DX.

If the concept of working DX being fun is alien to you, then it's time to wipe DXCC out of your mind and start actually talking with DX ops. A chap from

Spain sent me some flamenco CDs, so I sent him some ragtime CDs in exchange. Golly, I haven't visited Spain since 1976 . . . I've got to make some time to get over there again. And it's been even longer for Sweden and Aland! Meanwhile I'll be talking with the friends I've visited when I hear them on the air.

If you run into Father Moran please say hello and tell him I'm hoping to get some time to visit again. Ditto any of my friends In Sabah.

Oh, I almost forgot, yes, I know what you mean about the new no-code Techs. And no, I don't think we're heading toward a CB-like problem. Heck, if you've listened to 20m in the last year you know the mess Herb KV4FZ and his gang have made there is as bad as anything we've ever heard on CB.

I'm not sure credit is due to Herb and his destruction crew, but they sure have totally destroyed any pride we amateurs have had about amateur radio as compared to CB. I used to do a lot of CB operating and never in my life have I heard anything like the mess Herb and Baxter, K1MAN, have generated.

Self Education

While lecturing to a graduate student (MBA) class I mentioned several things which I expected any reasonably intelligent group should understand. Faced with a room full of blank stares, I asked for a show of hands on how many of them were reading any news magazines. You know, like *Newsweek* and *Time*. A few raised their hands—most didn't.

Hmmm, no wonder so few youngsters today have heard about amateur radio. Few of them have heard about *anything*. If they don't teach it in school, then it must not be important, I guess.

This almost tends to bring up a question we should be asking: How can we get word of amateur radio to the kids? This isn't exactly a new question. We've been asking it ever since amateur radio growth dropped into the pits 25 years ago. We've been asking it, but no one has been answering.

Some ham industry people got together a few years ago and worried the question. Someone suggested, "How about getting kids interested in hamming via comic books?" This eventually ended up with the ARRL sending out *Archie* ham comics. Tens of thousands of these later we still haven't seen any significant response. Do you suppose it may take more than one mention of amateur radio to get kids' attention? I notice that MacDonalds doesn't rest their whole business on one mention. Nor Pepsi.

Before I get into some possible ways of getting our message across to youngsters, let's just mull over this situation where our kids aren't reading any more than is required for school. That's bad news for them and for our society as a whole.

Firstly, since they haven't been reading, they may not even be aware of how seriously they're being shortchanged on their education. They may not realize that they are getting one of the poorest educations in the civilized world. Or that this has resulted in America losing its competitive edge in one industry after another.

Not knowing that they are being shuffled through our schools with a minimum education, they have no way to know that how educated they are in life depends almost entirely on their own initiative and that they're unlikely to get much guidance from their "teachers."

I was fortunate in a couple of respects. First, our school system wasn't nearly as bad 50 years ago as it is now . . . though it was bad enough even then. I hated it. Second, I had the marvelous experience of attending the Navy Radio Materiel School. How the government managed to actually do something right is inexplicable. No doubt a first. That school was fantastic. I believe it contributed significantly to our winning WWII.

The down side was that it was so good it soured me even further on our socialized compulsory education system.

The Reading Habit

Though I read quite a bit when I was young, it was mostly fiction . . . Tarzan, Tom Swift, Oz, Benchley, Potter, H. Allen Smith, and the wonderful Ernest Thompson Seton books, for instance . . . it wasn't until I got deeply interested in clinical psychology that I began to go heavily into nonfiction.

Kids today have a big world to keep track of. That means reading. I'd recommend *Newsweek* for general news (forget the daily newspapers), *Insight* for more in-depth news, and *The New Yorker* for real depth. I also highly recommend *The Public Interest* and *Foreign Affairs* for a better understanding of current events.

Reading these will also give you an enormous number of things to talk about on the air. And you'll be able to talk intelligently, not just express uneducated opinion based on a shallow understanding. People who've taken the trouble to know what's going on get fed up listening to that baloney.

I recommend that kids also keep an oar in the water on technology, too. They should have an understanding of current events in genetics, cosmology, particle physics, chaos theory, fuzzy logic, and so on. Magazines such as *Popular Science*, *Discover*, *Omni*, and even the *Scientific American*, will help keep you abreast of science developments.

If the Arabs we watched screaming and yelling in support of Saddam Hussein had had much education, I believe the whole Middle-Eastern situation would have developed quite differently.

How many kids today have an understanding of the major world religions? Of how they started? What the people believe?

Antenna Height Restrictions

A Florida ham complained that they've got a restriction on antenna

IT'S NICE TO FOOL MOTHER NATURE!

Unlike any other lightning protection device for coaxial transmission lines, I.C.E.'s Model 300 series requires no predetermined voltage to develop between conductors before voltage suppression begins. Units are constant drain, capacitor-blocked, non-DC passive, and each relies on a heavy discharge inductor paralleled with a ceramic gas-discharge assembly to provide a lightning-fast trap system for induced voltages.

Virtually indestructible, 300 series arrestors are built in 1/8" thick standard chassis enclosures with dual stainless steel mounting/grounding screws.

Over a thousand satisfied customers have chosen from the numerous models & connector choices offered. Each is packed with mounting hardware, storage box, and 4-page owner's manual.

(PATENT APPLIED FOR.)

SPECIFICATIONS

Attack time	Zero to 10ns, depending on induced waveform.
Surge current	8/20 us., 20,000 amps
Operating Temp.	-65 to 125 Celsius
Discharge Inductor	Toroidal, insulated.
Back-EMF ODU	600-1000V, ceramic body construction, G.I. Clare
VSWR	Less than 1.1:1 over rated spectrum
Insertion loss	Less than .1db
Impedance	50-75 ohms
Hardware	18-8 stainless hardware 8-32 stainless steel ground lug, 1/8" thick 5032-H32 case, 6-32 mounting hardware
Finish	Natural aluminum
DC resistance across	47K to 250K ohms, resistive
Capacitive effects	Less than 1pf
GOU specs.	Meets REA PE-80 IEEE 587 CCITT K12
Environmental	Recommended for indoor service at input bulkhead to station's grounding system. May be used outdoors if protected from direct rain exposure.
Warranty	One year standard

CIRCLE 132 ON READER SERVICE CARD

height in his neighborhood and the local authorities have ignored the FCC on the matter. He wrote to the ARRL and got stiffed. He wanted to know what I'd suggest he do. The local hams are at their wits' end.

I wrote, saying, "Yes, the ARRL certainly should do something about your lousy situation. That's what a real national ham organization should be set up to help with. The fact is that the League has been very reluctant to tackle legal cases to help hams. When I mention this I get angry letters claiming I'm attacking the League. No one ever tries to tell me it isn't true; it's just that I shouldn't mention it.

"Now, what to do. First, I recommend you start a petition around and get signatures. Get hundreds. What should the petition say? How about pointing out that in times of emergency, such as hurricanes, which are not unknown in Florida, the *only* practical source for emergency communications is amateur radio. You can quote from my editorials about the FCC's Long Range Planning Committee, which determined this was an absolute fact.

"To provide the needed emergency communications infrastructure, a service must already be in daily use–and this means antennas and towers. The beauty of amateur radio as compared to any other communications service is (a) amateurs are everywhere; (b) they fund their own equipment; and (c) they can provide long, medium or short range communications, as needed. I'd include some pictures of ham club communications buses and vans.

"Then get the signatures at every hamfest and other event. Don't let one single ham get away from Dayton without getting a signature. Get the manufacturers and dealers to cooperate with petitions at their booths.

"Politicians react very positively to long lists of signatures. That's what I brought to the FCC in 1973 when I initiated the biggest set of rule changes in the FCC's history.

"Find out who your enemy is. Which specific politicians are doing this? Then do whatever it takes to get them unelected. Make their lives miserable. Organize public confrontations, complete with the media invited. Picket.

"Who is the chair of the Florida League of Cities? Go after this person where he or she lives. Get local hams to picket this person as not caring about lives and families. Cite discrimination against technology. When a hurricane comes and lives are lost, and medicine and food are not available, then will the people who are supporting this monster put on some pressure?

"How about getting a video camera and staging some Mike Wallace-type live interviews with the offending politicians? You'll drive 'em crazy and get wonderful material for club meeting showings.

"I hope that is enough to get you started."

When you're faced with a problem like that, be creative. There's *always* a way to solve problems. . .even when you're dealing with the government. Well, almost always. . .there's always the IRS. . .

Kids

Have you been doing your homework like I asked you. . .or have you been doping off again? Well, while you were sitting there with a cold 807 in one hand watching a ball game, I was out there in the trenches for you. . .facing the enemy.

Wait'll you stand there, facing a whole room full of 10-year-olds, trying to explain amateur radio to them. You're not going to try and tell me that your local school isn't going to let you come in and talk to (with) the kids, are you? Give me a break! They'll be delighted and you know it. It's just that you haven't *bothered*.

Well, I put off some meetings at what I smilingly call "work" and had at a bunch of the local kids. I worked 'em over and got 'em all fired up. Now they're anxious to set up a station so they can get on the air and talk. What are you going to do about it?

You know as well as I do that you've got an old rig in the closet somewhere that you aren't going to use again. Even if it doesn't work very well (or at all), the kids will go bananas if they can get it and fix it. This is a lot better use for it than lugging it to a flea market and getting a few bucks. The money will soon be wasted on food and you'll have nothing to show for it except a little extra poundage on the scales. Well, I'll get you a letter from the kids telling you how much you've helped them.

Coincidentally, the same day as I talked with the kids in Antrim (NH), I got a call from the nearby Crotched Mountain Foundation. This is a rehabilitation center and special school for handicapped children. They're going great guns in getting their kids interested in hamming and they desperately need some gear for their station.

Kenwood, ICOM and Yaesu get a hundred or so requests for free rigs a week, so that's not where you turn. The real ham gear mother lode lies in your house. There are tens of thousands of old rigs out there with their electrolytics drying up and their transformers rusting.

A good friend of mine got the idea of collecting old, no longer needed oscilloscopes from labs and getting them to schools. This has almost turned into a business for him.

Well, I've got a little room left in my barn to store a few rigs so we can get them to schools that need them. I haven't got much room because we just cleaned up the barn and made enough room to build a state-of-the-art recording studio and that's filled a lot of the back of the barn.

The best bet will be for you to drop me a note telling me what you've got available in old ham gear. I'm starting with two local schools that need rigs, but I'll bet I'll get a hundred letters from other schools when they read this. I'll try and match your gear with a school. That way you'll know where it's gone.

If you'll start giving talks about how much fun amateur radio is to your local school kids, you'll get a real kick. They love the idea of talking to the world. They're excited about packet and talking with *Mir* and via our other satellites. They can hardly wait to start building things.

One of the projects I've got scheduled for my new recording studio is to start reading some books onto tape so we can put out books for kids on CDs and cassettes. I was amazed to find that almost 100% of the kids I was talking with are avid readers. Yep, they're actually reading books!

They'd all heard about the "Wizard of Oz," but most of 'em didn't know there are 13 Oz books. I'm planning on recording 'em all. When I was their age I read 'em all and loved 'em.

None of the kids (or teachers) had heard of Ernest Thompson Seton, so they've got a fantastic surprise coming when they hear me reading his books. I read 'em all when I was a kid. Over and over. They're wild animal stories told from the perspective of the animals.

I was surprised, too, that so many of their parents take time to read to their kids. Perhaps New Hampshire parents are different, but half of the kids in the class said their parents regularly read to them. That's what got me interested in reading. When I was young my mother used to read to me every noon when I was home from school for lunch.

For older people (and kids, too) I'm going to start reading the Kai Lung books by Ernest Bramah. Too bad if you don't know how wonderful they are. Maybe I'll get you to try a CD or cassette.

I'll be reading some poetry, too. . . probably starting with Eugene Field and his "Poems of Childhood." I've been surprised to find that many people aren't familiar with Field. Tsk.

It's fun to share enthusiasms with people. That's mainly why I'm into publishing. I'm sharing my love of music, poetry, books and amateur radio. You can share your excitement over amateur radio with the kids in your local schools. Help 'em get a club going. I'll see if I can round up some equipment from *73* readers to help. Let's dig out some of those old rigs, dust 'em off and see if they're working.

Send me a note telling me what you've got available. . .send it to: Rigs for Kids, *73 Amateur Radio Today*, Forest Road, Hancock NH 03449. 73

$329

Designed and built in the USA
Value + Quality from over 25years in ATV...W6ORG

With our all in one box TC70-1 70cm ATV Transceiver you can easily transmit and receive live action color and sound video just like broadcast TV. Use any home TV camera or VCR by plugging the composite video and audio into the front VHS 10 pin or rear phono jacks. Add 70cm antenna, coax, 13.8 Vdc and TV set and you are on the air...it's that easy!

TC70-1 has >1 watt p.e.p. with one xtal on 439.25, 434.0 or 426.25 MHz, runs on 12-14 Vdc @ .5A, and hot GaAsfet downconverter tunes whole 420-450 MHz band down to ch3. Shielded cabinet only 7x7x2.5". Transmitters sold only to licensed amateurs, for legal purposes, verified in the latest Callbook or with copy of license sent with order.

Call or write now for our complete ATV catalog including downconverters, transceivers, linear amps, and antennas for the 70, 33, & 23cm bands.

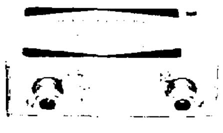
HIGH PERFORMANCE PRESELECTOR-PREAMP

The solution to most interference, intermod, and desense problems in repeater systems.

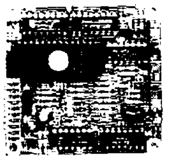


- 40 to 1000 Mhz tuned to your frequency
- 5 large helical resonators
- Very high rejection
- Low noise—high overload resistance
- 8 db gain—ultimate rejection >80 db
- GaAs fet option (above 200 Mhz)
- Cast aluminum enclosure
- N, BNC, and SO239 connector options

Typical rejection:
±600Khz @ 145 Mhz: 28db
±1.6 Mhz @ 220 Mhz: 40db (44db GaAs)
± 5 Mhz @ 450 Mhz: 50db (60db GaAs)
±20 Mhz @ 800 Mhz: 65db
±20 Mhz @ 950 Mhz: 70db

AUTOMATIC IDENTIFIERS

- Up to 8 EPROM programmed messages
- Adjustable audio, speed & interval timer
- "ID over voice inhibit"
- Low power option
- Modular design
- Message selection via binary input—TTL levels
- Size: 2.7 x 2.6 x 0.7"



NEW Model ID-2B

The ID-2B provides required station identification without troublesome diode programming. The "ID over voice inhibit" circuitry allows for courteous operation by not allowing an ID until the next squelch closing.

ID-2B Wired/Tested $99.95 **ID-2B-LP Low Power $109.95**

HAM HELP

Your Bulletin Board

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full (8½" x 11") sheet of paper. Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters l or i, or even the number 7. You may also upload a listing as E-mail to Sysop to the 73 BBS, (603) 525–4438, 8 data bits, 0 parity, 1 stop bit. Thank you for your cooperation.

Wanted: Instruction manual for operating EICO Model 232 VTVM. *Meyer Minchen AG5G, 4635 SW Fwy., Houston TX 77027. (713) 622–6161.*

A Kenwood TS-140S was stolen from the Towson State University ARC on Nov. 25, 1990. Its serial number is 9100556 and it has a TSU property tag #144378. It had no optional filters and was about a year old. The TS-140S was our only piece of high-quality modern gear and it will be extremely difficult to replace. Anyone with information should contact *John Egger K3GHH, Towson State Dept. of Economics, (301) 830–2954.*

Calling all Vietnam-era MARS Operators! MARS officials have asked Dr. Paul Scipione AA2AV (MARS callsign AAA9PR) to write a book about the history of MARS operations during the Vietnam War (1964–1975). Scipione has developed a database of more than 200 Nam MARS ops, but estimates there are several thousand more. If you are one, or know one, please contact Scipione for a MARS Nam questionnaire. His book (to be published in 1992) will have a section with the names and current callsigns and QTHs of MARS Nam ops, to help reunite old friends. Write *Scipione AA2AV, 5 Burr Drive, Metuchen NJ 08840*, or call *(908) 548–8096*.

Please help. I need some crystals for Heath HW-16 to get a new Novice on the air. I will pay the postage. Send info to *Jim Clark WD5HMM, Rt. 1, Box 468, Cleburne TX 76031*. Thanks.

I am a veteran of the Afghanistan conflict, and would like to organize a meeting with American ham Vietnam veterans to discuss world peace. Last summer nearly 80 Soviet vets got together and worked with the special call, R3AFG (Russia 3 Afghanistan). Their goal is to invite American vets to the Soviet Union during the summer of 1991. If interested please write to *Alex Marchenko UA0CT, P.O. Box 1, Garovka-2, Khabarovsk 682305, USSR.*

Wanted: A copy of the manual for Collins 516E-1 or 2 mobile power supply. I will pay costs. *J. Orgnero, Box 32, Site 7, SS 1, Calgary AB T2M 4N3, Canada.*

I am a Novice and would like to obtain info about equipment for fox-hunt sniffing. I need to know what companies sell it, what is commonly used, and how small the transmitters can be made. *Bob Walker, Box 65, Galiano Island BC, Canada.*

I need a copy of the schematics or booklets on the SBE-33 transceiver, the Hallicrafters SX-101 receiver, and the Hallicrafters HT-34 transmitter. If anyone knows of any upgrades or improvements to these, please let me know. I will pay reasonable copying costs. *Paul Christie ex K2UKT, 208-27 15th Road, Bayside NY 11360.*

Needed: Manuals for Regency MT-15 and MT-25 marine 12-channel, commercial BTH 201/301/204 etc., 1, 2 and 4 channel, and some UHF. Please send me a post/QSL card stating what you have, copy fee, or whether you are willing to lend for me to copy. Many thanks. *David J. Brown W9CGI, 14670 N. Cumberland Rd., Noblesville IN 46060*, or FAX via *Jim Adams WA9BHF, (317) 253–8384.*

I am looking for two books. One is the MCS-65 Users Manual for the 8085 microprocessor. The other is published by Zilog for its Z-80 series microprocessors, explaining pin functions and machine language instructions. Thanks, in advance, to all who can help! *Scott A. Littfin N0EDV, P.O. Box 1215, Hayward WI 54843.*

I need documentation and/or software/hardware supporting the RS Model III and a Sanyo "Silver Fox" MBC 550-2. Any help appreciated. *M.M. Barrette N1GPV, 21 Breton Ave., Sanford ME 04073-3236.*

I am 14, and working on my Novice ticket. I would like to ask all the hams out there if they have any extra stuff just collecting dust which could get me started towards my Extra license. I would also like to ask if any ham in the Modesto, California, area has any interest in helping me get my Novice license. I'm having a lot of trouble with the code. *Brandon Wilson, 920 Briggs Ave., Modesto CA 95351.*

Wanted: Literature for Cushcraft antenna models A-147-11, 124-WB and Ten-3. Also, schematic for Heath HWS-2 hand-held transceiver. *Glenn Torres KB5AYO, Rt. 1 Box 580-B, Reserve LA 70084.*

Law student gathering info for thesis. If you feel the FCC has ever violated your constitutional rights, please send a brief summary to *George F. Arsics, Jr., 2571 Bethany Ln., Powder Springs GA 30073.*

Needed: Diagram for a Bear-Cat BC-250 scanner and any info on modifications. Also need manual and diagram for Tempo One or FT-200 Yaesu transceiver. Any one have programs for RS Model 4 computer for ham radio? Need also diagram for CW/filter/enhancer that appeared in *QST* a few years ago. Will pay copying and shipping. Send quote to *Patrick Benesch KN4MA, Gen. Del., Loyall KY 40854.*

Please send me names and addresses of people or companies who supply communications software for the Atari 520/1040 STE computers. Also, systems to send and receive CW, RTTY (Baudot & ASCII), modified ASCII, etc. *Leonard Saddler, 1420 Reeve Ave., Bakersfield CA 93307.*

I need copies of any and all available documentation (manuals, software, schematics, etc.) for the Seequa "Chameleon" portable computer. This machine, circa 1984-85, had both 8088 & Z-80 CPUs, and could run MS-DOS & CP/M software. Will supply disks and pay costs. *T. Mark Long, 901 Chalk Level Rd. Apt. V-11, Durham NC 27704. (919) 471–3147. Evenings & weekends.*

DESPERATE!! I need an inexpensive tranceiver and/or antenna for any band 6 meters thru 440 MHz. Have my license but not a lot of cash to buy equipment. I hope someone out there can help me, I'm dying to get on the air. I'm not fussy. Please write me if you have a spare rig you would like to sell to someone who would greatly appreciate it. *Dave WB1FDZ, P.O. Box 892, Northboro MA 01532.*

I am in desperate need of an owner's manual for an IC-730. Will pay all expenses for good copy. Call collect between 8 a.m. and 1 p.m. CST. *(501) 898–6716.*

I am helping John Allen Phillips, 424 W. Cedar, Durant OK 74701 to become a ham. He has been blind since 1977. He has no equipment except a code practice oscillator I built for him. Any used ham gear would surely be appreciated. Thanks. *Randy E. Cassels KA5JTX, P.O. Box 11, Atoka OK 74525. Mr. Phillips' phone number is (405) 924–2386.*

I am looking for any information on any Wilson tribander 3-element beam antenna. I will pay any cost involved. *Don Lloyd KN5OQ, 810 Wolf Trail, Casselberry FL 32707.*

Old-timer, since 1929, desperately needs used HF transceiver, preferably small, like IC-735, FT-757, Argosy II, etc., in good working condition. Many thanks in advance and best 73. *Zbigniew M. Rybka SP8HR, ul.Radzynska 18 m.66, 20-851, Lublin 57, POLAND.*

Wanted: Manual/schematics for Scott Instrument Laboratories telemetry FM receivers, models 1312-1 through ? More than happy to pay for originals or copies. *W6HNI, P.O. Box 1017, Carpinteria CA 93014.*

I have a Kenwood TR-2500. I am looking for the TU-1 tone unit. Please contact me. *Ken Chaffee KK6VU, 36983 Oak Glen Rd., Yucaipa CA 92399.*

I am looking for the Ludvigson Tonegen, reviewed in the Feb. '88 issue of *73*. The address has changed and is not in the directory. Does anyone have a copy they could share? I will gladly pay postage and expense. *Gary Sherard WA5FLV, 700 D St. SE, Miami OK 74354, phone (918) 542–7142.*

Wanted: Digital readout. Modification kit for Ten-Tec Century 21 (Model 570). Thanks. *N0LHJ, 493 Ironwood Dr., Ballwin MO 63011.*

QRP DX?

I did something this year that I never intended to do. I've been telling people for years that I wouldn't do it, no way! But I did it anyway—I operated QRP!

I operated QRP during the early hours of the ARRL International DX CW Contest. I don't know what caused me to do this, excessive sunspots or middle-age crazies (my XYL suggests it is over-the-hill crazies). Whatever it was, I just sat down in front of my 100 watt transceiver/kW amplifier station and "unloaded" my transceiver to 5 watts and proceeded to work stations.

It was easy (uh, relatively easy), and within the first hour of the contest I had worked enough stations to qualify for the Worked All Continents Award. After that, with WAC under my belt, I was really hooked. The adrenalin was pumping, and I was having fun.

I started working on DXCC/QRP. It seemed to be as easy as working stations on a kW, but then I realized that it wasn't. It took a few more calls to work each station. I had to use good DX operating techniques; I was stalking new countries, aiming correctly, and hitting the target. One hundred QRP countries were within sight.

This brings us to this month's column, and the topic of champions—DXing techniques. We'll begin a series of discussions that may be of benefit to all DXers.

DXing Techniques

Though it helps, you don't have to have high power and big antennas to successfully work DX. In most cases, technique is more important than power. Most stations outside of the U.S. run 100 watts or less, but they are still successful.

What are good DXing techniques?

Almost anything you do that yields another notch in your country count is a good technique, as long as your behavior in the pile-ups is reasonable and ethical. You should not cause undue interference, call out of turn, call the DX station long distance to arrange a QSO, etc.

If you spend 15 hours in the same pile-up to work a station, your technique—if it can be called that—is faulty. *The secret to successfully working a DX station is to put your signal on the frequency where the DX station is listening.* It is that simple. But, of course, it helps if your signal is the only one on that frequency, and the DX operator is cooperating!

The DX Operator vs Technique

The best technique in the world, even coupled with high power and big antennas, is often of little use if the DX operator is a poor operator. Here are a few examples. A DX operator who sends CW at 50 wpm often creates confusion, because many calling operators cannot understand his instructions (such as JA only, Europe only, UP 10, etc.). A DX operator who asks for USA only, then proceeds to work Europe is asking for trouble, confuses the callers and makes your job more difficult. A DX operator who states "UP 10," but who in fact is working stations 5 kHz below or 40 kHz above his frequency is difficult to work.

Practical Techniques

Okay, let's discuss techniques. There are only a handful, but with numerous variations. Each one may be modified to suit your needs or the situation.

First: *Listen, listen, listen!* You must listen to the DX operator and understand how he is working other stations. It is usually foolish to jump into a pile-up without first understanding what the DX operator is doing, where he is listening, and whether he is working split or on his own frequency.

After listening to the DX station for a few minutes, confirm his identity. Then note whether he is taking full callsigns only, parts of callsigns, or repeatedly "QRZeding" when he cannot pick out a callsign. How fast is he working stations? Is he working stations on or near his own frequency? Is he announcing where he is listening? Is there a distinct break between each station he works?

Second: *Listen to the policemen.* The policemen on the frequency can often provide clues about the DX operator's operating pattern. If they continually say "UP 10, DWN 5," or such, the DX operator is working in split frequency mode, or "split" operation. That is, he's listening on one frequency and answering on another. His listening frequency may be either above or below his transmit frequency. In split operation, the separation from his frequency will usually be from 2 to 10 kHz on CW. On SSB, separations of 5, 50, 100 kHz or more are not unusual.

Third: *Listen to the stations he is working.* Listening is the name of the game. If you cannot hear these stations, try rotating your antenna to see if you can find them.

If he is working stations on or near his own frequency, determine how close to his frequency they are. And, is there a pattern? Always a 100 Hz higher? 200 Hz? Does he work stations farther away from his own frequency each time, but never more than a half kHz or so?

If the stations he is working are on his own frequency, your task is simpler in one respect, but more difficult in another. You'll be sharing the frequency with all of the other callers.

If you have determined that he is not working stations on his own frequency, your task is to find the pile-up of stations who are calling and working him. He is working "split," and he may be listening almost anywhere, but hopefully not too far from his transmit frequency.

The DX operator may specify where he is listening, or the policemen may offer a clue (as explained above). If not, then you must hunt for the group of stations calling him. This task is more difficult if more than one popular DX station is active in the same area on the band.

Finding the pile-up on SSB is easier if the DX operator is operating on what we call "the usual DX frequencies": 14145, 14195, 21295, etc. In this case, "the usual calling frequencies" are: 14150–160, 14200–210, 21300–310, or some reasonable variation. Don't forget to check below his frequency, too.

Until next month: listen, listen, listen, and try to understand what each DX operator is doing before you call and call. Next month, we'll discuss how to put your signal right where the DX operator is listening.

73 INTERNATIONAL

Arnie Johnson N1BAC
103 Old Homestead Hwy.
N. Swanzey, NH 03431

Notes from FN42

One of the great things about working for 73 is that I have access to many international electronics and ham radio magazines. Some of these magazines are published in English, and others are not. And I only speak, read, and write in one language, English.

I have a few of these magazines sitting on my desk right now. They represent the Soviet Union, Czechoslovakia, Switzerland, Italy, Germany, and Australia, each in its native language. What can I do except look at the pretty pictures?

Well, I can read the schematics to a great extent. Circuit layout, and the symbols for values and most components, are universal. In some countries, the convention is to use a comma instead of a period to represent a decimal, but that's not too hard to figure out. The only difficulty I might have is with some of the labels; inputs and outputs, for example, are in the native language.

In the text, the callsigns are in letters and Arabic numerals. I can see similarities among the languages, though I'm no linguist. Certainly, what's most important is that all these magazines were developed with the love of electronics and amateur radio as the focus. Regardless of the language, they convey that love, and also the desire to further our knowledge of the world around us.

I am sorry I don't understand all these languages, as I know I would learn a lot more about this hobby that I love. I had to put my desire to learn basic Russian on the back burner, as we say, because I had too many irons in the fire. Hopefully, I will be able to resume my attempt in the fall. Even a little learning makes the world a better place; though people speak different languages, we all have much in common.

A couple of items regarding the April column: The name of one of the members of the 4X90BS crew (Photo E, April 1991) was left out. He is Motti 4X4PE, 4th from the left on the top row between 4X6YY and 4X6EA. Next, look at Photo C. A new prefix for you prefix hunters? No; the photo was unintentionally reversed during production and printing. Sorry, Tino. At least we got the callsign right in the photo caption.—Arnie, N1BAC.

Roundup

Japan From the JARL News: The annual JARL-sponsored Ham Fair, one of the biggest events of its kind, will be held at the New Hall of the Tokyo International Trade Center at Harumi, Tokyo, as last year. Ham Fair '91 will run from Friday, August 23 through Sunday, August 25, 1991. Last year this fair attracted a total of 59,000 visitors.

On the first floor will be various events, including a much-waited special commemorative radio station, 8J1HAM. Not to be forgotten will be the JAIA Fair (sponsored by Japan Amateur Industries Association) displaying their tempting array of various updated and sophisticated equipment.

On the second floor, many amateur radio clubs will be giving a full account of their activities and selling heaps of "junk" at their own booths, midst a friendly and exciting atmosphere.

Next in *The JARL News*, the All Asian DX Contest Schedule has been changed so as not to coincide with the annual Ham Fair. Effective this year, the schedule is as follows: PHONE: The first Saturday of September, from 00:00 UTC through 24:00 of the following day (instead of the third Saturday of June); CW: The third Saturday of June, from 00:00 UTC through 24:00 of the following day, instead of the fourth Saturday of August.

Included in the JARL newsletter were "Rules of ARDF Competition Amended" and "Extension of the 'WARC '79' Award." Both provided lengthy information and will be placed in the 73INTL Special Interest Group portion of the 73 BBS (connect info provided on the "Table of Contents" page of the magazine).

U.S.A. Although most hams were aware that the April STS-37 shuttle mission had an all-ham crew, much of the public didn't know. Thanks to *The Wall Street Journal*, many more will now know. Featured on the front page of its March 28, 1991 issue was "Hams in Space," informing the reader that all five astronauts on the coming *Atlantis* shuttle flight are licensed amateur radio operators. Also, it stated that the first all-ham crew was inspired by its pilot, Ken Cameron, who's active in radio education.

U.S.S.R. Andy Fyodorov RW3AH writes: "Big Circle" is a unique undertaking that includes several dog sled expeditions to northern regions of Asia, America, and Europe.

In 1990, the "Big Circle" expedition passed across the Chukot Peninsula, and ended on Wrangel Island in the Arctic Ocean.

In 1991, there will be an expedition to the North Pole.

In the 1992–1995 period there will be expeditions in the "Super-Arctic Circle" series through the snow and ice of the Chukot and Alaska peninsulas, and the arctic regions of Canada, Greenland, and Scandinavia. Americans, Russians, and representatives of other northern nations will take part in these expeditions.

[Andy sent his QSL card which depicts the friendship that has developed between the U.S.S.R. and the U.S.A. Just think what might happen if more common ventures are started between countries throughout the world. Amateur radio has been doing these things for many years.—Arnie]

ISRAEL

Ron Gang 4X1MK
Kibbutz Urim
D.N. Hanagev 85530
Israel
Packet: 4X1MK@4Z4SV.ISR.EU

Israel gets 6 meters! I'm happy to report that since the beginning of February, a sliver of the 50 MHz band has been made available to Israeli radio amateurs. It should be noted that this band is not an amateur allocation here in ITU Region I, yet due to the interest shown by amateurs in Europe and Asia in the band, certain countries have been opening up some of the spectrum. Happily, Israel has now joined them, and 4X/4Z will be a sought-after prefix on 50 MHz.

Operating conditions are somewhat restricted: Only Class A licensees may operate on 6 meters and from 50.100 to 50.150 MHz with a maximum output power of 25 watts. Nonetheless, when the band is open, as it is now quite often here at the peak of Sunspot Cycle 22, you don't need too much power to get out!

By the time you are reading this, hopefully Morel 4X1AD will already have his SSB/CW station operating on the band. Six meter enthusiasts are advised to listen as well for weak FM signals, as it is possible that some stations will be activating military surplus gear.

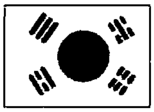
Lithuanian Amateur Radio Conference. By now, many of you have already made your plans for the Lithuanian Amateur Radio Conference scheduled for the first week in June in Vilnius, Lithuania. Even though we are still experiencing some political problems, conference plans are still continuing.

We are not the only ones that are continuing with our plans. Other organizations are holding conferences and group meetings, including an international folk dance festival. Come and have a good time with us.



REPUBLIC OF KOREA (SOUTH)

Byong-Joo Cho HL5AP
PO Box 4, Haeundae
Pusan
Republic of Korea 612-600

Commemorating the 30th Anniversary of Amateur Radio Operation. Thank you very much, everyone of the world, for your contacts on the air under the special callsign of HL30AP from September 1 to December 31, 1991. It has been 30 years since I began operating under the callsign of HM1AP *[the second first class amateur radio operator license issued after HM1AD]* when Korean nationals began operating in 1960.

I started up with a home-brew rig, using an 807 tube in the final and running 15 watts. I contacted many DX stations all over the world. I would like to express my sincere appreciation for all of your warm friendship and goodwill extended to me. I'll cherish the excitement and joy I've shared with so many amateur stations, and hope our mutual ham-life continues prosperous.

I have made a special QSL card for HL30AP, and I would like to send it to all who have made contact with me under that call. Please send your QSL with an SASE.

During March 9–12, 1991, I visited Taipei, Taiwan, for the inaugural meeting of the Chinese Taipei Amatuer Radio League (CTART). At the general

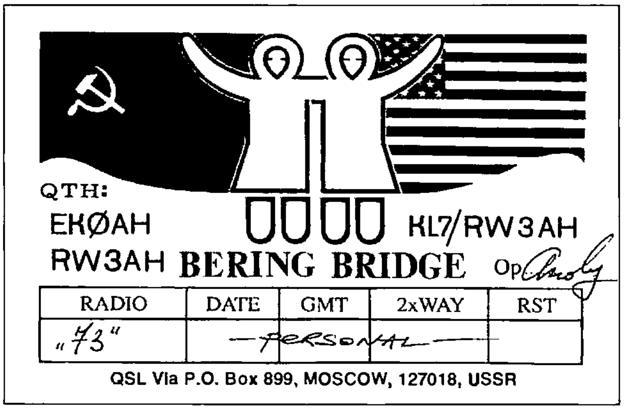


Photo A. The QSL card of Andy RW3AH commemorating the Bering Bridge, the bridge between the U.S.S.R. and the U.S.A.

Photo B. The special QSL card of Byong-Joo Cho HL3ØAP/HL5AP commemorating 30 years of amateur radio operation. Clockwise, beginning at the callsign, the photos show: 1961, 1970, 1975, and 1990

meeting there were many guests, including Mr. Rankin 9V1RH/VK3QV, chairman of IARU Region 3; Mr. Hara JA1AN, president of the JARL; Mr. Song HL1CG, on behalf of the KARL president; and Mr. Uchibori JA1IRT, editor of *CQ Ham Radio* (Japan). I attended as a guest of the KARL as an elder statesman (charter member). Some Okinawan hams and about 300 members of the CTARL attended. During this celebration, they operated their league station BVØARL.

If you need a contact from anyone in BV-land, I can introduce you to one of my friends who is very active on SSB and CW from Taipei. He is also a keen award hunter. 73 for now.

YL World '91. Last year a group of Swedish YLs attended a YL convention in Hawaii, and decided to arrange a YL meeting in Sweden in 1991. This event, called "YL World '91," will take place in Stockholm, Sweden, during the midsummer festivities. By the time this is in print, the deadline for registration is probably past, but if you are going to be in the Stockholm area around June 20–23, you may call Kerstin SM5EUU, phone +46 21 33 04 85, for information. SKØYL will be active during this event.

International CW traffic net. The Scandinavian CW Activity Group (SCAG) was formed in 1974. The idea was to practice message handling. Some difficulties were encountered in the beginning because of different thoughts about third-party traffic. Our thinking was that handling messages about amateur radio matters between licensed radio amateurs could not violate any third-party traffic restrictions. Why wouldn't you be allowed to send a message to a ham operator through another ham operator? If you can talk with him or her directly, why shouldn't you be allowed to have a message passed to him or her? However, to forward a message to a person outside the ham ranks is not allowed here. *[Maybe changes will happen—Arnie.]* SCAG is running an international CW traffic net every Saturday at 1100 UTC on 14.065 MHz. Net control station is SK7SSK. See you there.

Take to the Road

Now that Field Day is approaching, you might think about taking your ATV station on the road. Each year a number of ATVers set up at Field Day sites and have fun exchanging pictures.

If you plan to operate ATV during Field Day, alert the locals and rack up a few new points. It's also a lot of fun to show those who decided to stay home just how much fun you're having (mosquitos don't show up well on video). Who knows, maybe a close-up camera shot of some of that fantastic food may convince some more folks to come out and operate! The ATV crew at last year's Nashua (New Hampshire) Amateur Radio Club (NARC) site spent a lot of time filming their complete on-site kitchen. That way they were close by when the next batch of goodies appeared. Not only did they have a full-sized electric range (they even baked cookies!), but they brought along a refrigerator stocked with ice cream. I understand that next year they'll include a kitchen sink!

A Field Day site is also a great place to demonstrate ATV to your club members and any visitors. A couple of years ago, we encouraged a number of area groups to bring out ATV to their Field Day locations. To ensure that they had something to watch, Mel Alberty KA8LWR and myself went up in his Cessna 172 to about 10,000 feet. We had a blast working several sites across Ohio and Michigan.

Portable Demos

You don't have to wait for Field Day to set up an ATV demonstration. Summer is a great time to put on a show at your local county fair or special event. Rod Fritz WB9KMO did an interesting demo for the Brooks Institute of Photography in Santa Barbara, California. He set up a link from the institute down to a nearby shopping mall via 434 MHz ATV. One of the students at the institute put on a skit about repairing appliances. Down at the mall, people crowded around the TV set to watch "Mr. Fix-It Man." Little did they realize that the fix-it man could see them via a 10 GHz link back up to the Institute. In the middle of his spiel he'd point at one of the audience and ask them a question. You can imagine the shocked reaction. Some pretty lively exchanges resulted, all done via a full-duplex ATV link.

If you plan to do a number of "road shows," you may want to organize your equipment to allow for a quick setup. Members of the Bayonne Emergency Management Amateur Radio Club (BEMARC) in Bayonne, New Jersey, have been giving demos to a number of area radio clubs. John WA2QYX, Danny N2EHN and Mike KB2EQQ have modified Danny's van for some portable ATV action. When they arrive for a club demo, they usually set up the van at a nearby interesting location, such as a busy intersection or shopping area.

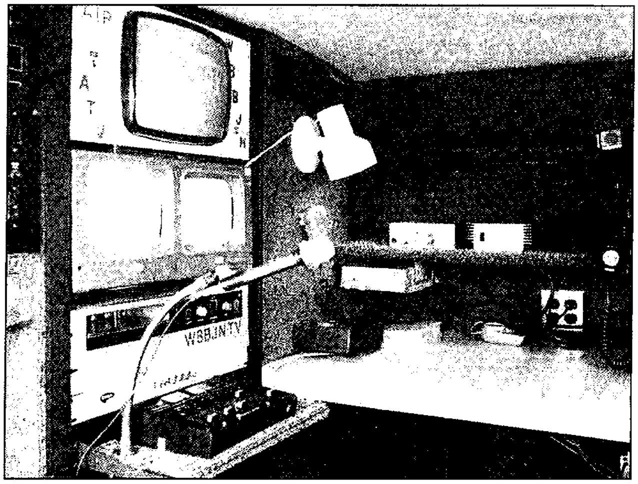

Photo C. Inside of the HAMCAM showing the ATV transceiver and 2m station nestled on shelves in the back of the van.

Mike KB2EQQ usually starts the ATV program inside the club and then has Danny and John transmit an outside view back into the clubhouse. Usually a few of the club members come out to be momentary TV stars. A few random interviews of innocent pedestrians may have the potential of a "David Letterman" style show. See "Hams with Class" in the February issue of *73* for more on the BEMARC club's activities.

If you plan on doing a lot of ATV road shows, you may want to build up your own dedicated minicam truck just like the commercial TV stations. Amateurs in central Ohio have done just that!

The HAMCAM

Gene Kirby W8BJN received an interesting offer back in July of 1989. A fellow ham who worked at a nearby commercial TV station (WBNS) explained that their station was retiring one of their RAPIDCAM remote TV trucks and wanted to offer it to the Union County Amateur Radio Club (Marysville, Ohio).

The club jumped at the chance, and proceeded to refurbish the aging vehicle. After a little body work and some fresh paint, they were ready to put in the radio equipment.

They installed a PC Electronics ATV transceiver (TC70-1) and beam antenna, video switcher, three rack-mounted video monitors, sound board, tape deck, VCR, amplifier and two video cameras. Next they installed a KWM-2 for HF, a 2 meter FM rig, a CB and a Civil Defense radio. They had a little room left over, so they threw in a scanner to monitor emergency service frequencies as well.

The completed HAMCAM has two operating positions. One is dedicated to HF communications and the other operates on ATV and 2 meter FM. Each position is designed for easy access to the equipment and is quite comforable for extended sessions due to the large plush chairs and air-conditioning (a heater is available during the winter).

Once at their destination, it just takes a few minutes to swing the antennas up to their operating position, set up the two TV cameras on tripods and put the HAMCAM on-the-air. After that, the operator uses his video switch panel to select between the two camera views and to watch any incoming ATV signals. The two camera views are continuously displayed on two of the monitors. The third monitor is used to receive ATV from a remote site or command center. They even have big floodlights installed on top of the van for night duty!

Emergencies/Demonstrations

The Union County club plans to use the HAMCAM to help out in emergencies, demonstrations, parades, fairs or anywhere a portable command station is needed.

You don't need an actual TV minicam truck to build your own HAMCAM. Good-sized vans can be obtained fairly reasonably if you're willing to do a little maintenance. It sure makes a good club project and can really help out your community in an emergency. 73

RANDOM OUTPUT

David Cassidy N1GPH

I didn't think this topic would come up again, but it seems the debate over no-code is STILL raging. Can you believe it? Here we are, over four months after the first no-code Technicians received their licenses, and a large group of Neanderthals within our midst continue to bitch, moan, argue and predict the doom and demise of amateur radio.

Today I received a copy of a letter, sent to the FCC by an amateur radio club in California (I won't embarrass the members of this club by revealing their name), signed by the president of said club, listing all of the reasons why this particular group of geriatric amateurs was opposed to the no-code license. If these folks wanted to have their opinions heard on the matter, why did they wait until April to do it? Kinda' late now, boys.

To be sure, there are plenty of intelligent amateurs out there who have a problem with eliminating the code requirement. Some of the more interesting QSOs I've had in the last few months have been lively discussions of this issue. But having a well-formed opinion and expressing it with intelligence is worlds away from what I'm hearing on the bands—the same old stupidity, parroted over and over, by a bunch of old men who probably haven't touched their code keys in 20 years and couldn't pass a 13 wpm code test if their lives depended on it.

One more time, for the brain-dead, let's examine the major objections to no-code. Pay attention. This is the last time we are going to go over this.

"Having a code requirement maintains the quality of amateur radio licensees. If we eliminate the code, ham radio will become like CB." Anyone who has this opinion obviously hasn't spent any time on the bands lately. The goofballs on 14.313 MHz, the illegal and shameful behavior of many trying to contact the Bouvet Island DXpedition (or any even slightly rare DX spot, for that matter), 10 meters during a contest weekend, AMers on 40 meters with 20 kHz bandwidths (I have nothing against AM, but I have a lot of problems with 20 kHz bandwidths)... All of these folks (and these are but a few of dozens of examples) are licensed amateurs who have passed a code test. If you're a rude and obnoxious jerk, a code test is not going to change that. If you're a courteous and thoughtful operator, the lack of a code test will not turn you into a net-jammer.

"We must maintain the code requirement because code gets through when other modes don't. It's vital in times of emergency." This argument may have had some validity 50 years ago, but with modern communication modes and equipment it is simply no longer true. You can put up a dipole, pump less than 100 watts of packet into it and get an error-free message, anywhere in the world, delivered in less than 24 hours. And you don't even have to be in your shack to do it. You could send a message to yourself before you got on a plane from New York to Los Angeles, and the message would be waiting for you before your plane landed. If I had an important message to send, CW is the last mode I would choose. It's slow, inefficient and more prone to operator error than any other mode.

"Morse code is a radio tradition that should be saved. It's a useful skill that all radio operators should know." This is the dumbest argument yet, but you'd be surprised how many times I've heard it. Being able to shoe a horse is a useful skill, but I don't think it should be a requirement for obtaining a driver's license.

"The no-code license was pushed through the FCC by the major equipment manufacturers, so they could make millions of dollars in new equipment sales." Oh, how I wish this were the case. I have a very large streak of 1960s' "angry young man" in me, and this kind of a scandal would be perfect. Unfortunately, it just isn't true. I speak with the marketing managers of every major amateur equipment manufacturer on a regular basis—some of them I consider friends—and not once has any of them even brought up the subject of no-code. For most of these companies, amateur radio is a small sideline to their commercial electronics business. They are not sitting around waiting to make their fortunes off of amateur radio. The only people getting rich off of amateur radio are the ARRL (sorry... I couldn't resist).

"Unless you give these no-code Technicians special callsigns, how can we make sure they're not operating illegally?" Boy, the dopiness just keeps on comin'. I have a 1 x 3 callsign. If you hear me calling "CQ" on 15 meter SSB, how do you know that I'm not a Technician? You can look me up in the *Callbook*, but that information is at least four months old. I could have upgraded since the last edition was published. How do we know that any of us are really licensed to be transmitting where we do? I'm sure that hundreds of amateurs operate out of their allocated frequency privileges. I've even heard a few that I KNOW were operating illegally. So what? Most amateurs are like you and me. They respect the FCC regulations and operate according to their license class. Does passing a code test guarantee that you will only operate within your assigned frequency limits? No, of course not.

When you come across someone on your local repeater, or when the regular group of crotchety old farts on 40m starts up again about no-code, please do us all a favor and tell them to shut up. Amateur radio has changed. The rule passed. The no-code license is here. Get over it.

I've received dozens of letters from no-code licensees. Some have told stories of friendly local hams, welcoming them to the hobby. Others have had stories of rude and obnoxious idiots refusing to talk to them because they haven't passed a code test (no great loss—these dopes aren't worth talking to anyway). Most of these new licensees have mentioned that they are continuing to study the code, so they can get on HF.

Those of you who were around when the Novice license was first instituted will see a big similarity. Novices were shunned. The Novice class was going to be the demise of amateur radio. The same thing happened with Novice enhancement. Letting the Novices on 10m was going to be the end of amateur radio. Hell, the same thing happened when SSB was introduced... or 2m repeaters... or pick any change since the days of spark gap.

How you or I feel about no-code is a mute point. It happened. It's done. Now, let's all move forward and start addressing the real problems in amateur radio. If you insist on clinging to this non-issue, then the least you can do is keep it to yourself. The rest of us have more important things to do.

Not Great, But Not Bad

Overall, June will be a fair month for DX, but not as spectacular as spring and fall. Sunspot Cycle 22 has begun to decline from its estimated peak in June 1989, and is now in its second downward year of an approximately six-year period when the sunspot minimum is expected (1995–96). DX will continue to be good to fair for the next couple of years, but you'll need more skill and information to maximize your success because opportunities will be fewer and farther between.

June always centers on the "DX Doldrums" because it marks the summer solstice, halfway between the spring and fall equinoxes when DX is best. The higher summer sun angle in the Northern Hemisphere heats the F2 layer, reducing ionization of the upper atmosphere. With the atmospheric noise levels and reduced ionization, DX opportunities are consequently reduced.

Although daytime DX will generally be poorer in June compared to winter, late evening DX may be better because of the longer hours of daylight. There are also VHF/UHF possibilities in June, and it's a good idea to look for sudden ionospheric and atmospheric disturbances that can promote them.

The expected poor days for this month will center around the 11th and the 22nd. The rest of June is expected to have poor to fair DX propagation conditions; but don't expect the results you get in spring and fall.

The charts may be used in two ways: To find an appropriate time and band to work the countries you need, or to take advantage of the operating hours you have available, and work those countries most likely to be open at those times. Then, consulting the daily calendar forecast, you can choose the days most likely to be best for success.

For more information about shortwave radio propagation, I recommend the *Shortwave Propagation Handbook*, by Jacobs and Cohen.

LETTERS

From the Hamshack

Dan and Sue Cashin, Havertown PA As semi-regular readers of *73*, we'd like to let you know we find it an interesting publication. We especially enjoy your "Never Say Die" column. It's thought-provoking, interesting, and just plain good common sense!

We've been considering getting our ham tickets, but have not quite decided what the hobby will do for us. We're dedicated SWLers and enjoy the world at our fingertips. What is the hobby of hamming all about? Is it a world of contests, quick contacts, and QSLs? Is the soap opera we hear on 14,313 typical of ham nets? What types of nets are there? This is a high cost hobby, and we've not hit the lottery yet.

I'd like to propose an idea to go along with your new *Radio Fun* publication. Why not a net like ANARC's Sunday morning SWL net? There could be gateway stations to answer prospective amateurs' questions. It could serve as a place where interested people could get straight answers from people in the hobby. ANARC is on 7240 LSB, 10 a.m. East Coast time, with Bob Brown KW3F as net control.

Keep prodding and pushing for progress, and who knows, maybe we'll get to talk on the air some day soon.

Amateur radio is mostly about a half million or so people around the world who are having fun. Some do it with nets, talking to people with similar interests. Some chasing DX and fighting the pileups. Some with a hand transceiver on their belt, keeping in touch with friends in the area. Some in club work. Some in talking through our several satellites. Some in bouncing their signals off the moon. Some in building kits and designing new equipment. Some in microwave experimenting. Some in exchanging messages via their computers and packet radio. Some using radio teletype. Some with slow-scan TV. Some with regular fast-scan TV. Some send miniature TV cameras and transmitters up in balloons. Some get together on Saturdays and try to find hidden transmitters. Some get involved with contests. Some go to rare spots around the world and operate for a few days, making thousands of contacts. Some spend their time teaching newcomers. Some write long editorials. Amateur radio is a whole bunch of hobbies. Oh yes, some get their fun by getting on 14,313 and cursing out the others. Some send endless "information" bulletins on 14,275. One ham recently chose to try and mess up the DC police... and got arrested for his trouble. Our hobby has something fun to do for every temperament.

Money? It's easy to get once you get the hang of it. I find the harder I work, the luckier I get.... Wayne

Jeff Wilson N9IMJ, Carlinville IL I read your magazine regularly, and I can honestly say that it is the best magazine printed in the field of amateur radio. I especially enjoy your editorials, and in particular the ones that display a "get up off your duff and do something for your hobby" motif. Frankly, I'm as lethargic as the next person, but I cannot understand why any ham who is perfectly capable of it won't in some fashion attempt to better the hobby or promote amateur radio to the public.

The area in which I reside has quite a few amateurs, but very, very few active amateurs—ones who still have and use a radio. About a year and a half ago, eight of us active hams formed a club. Despite our small size, we have managed to organize Field Day in an area where the public could see us and ask questions. Every year we provide communications for the Multiple Sclerosis Walk-a-Thon. Our club gives demonstrations for interested groups, and lately we have offered a class in amateur radio to about 12 people. I can't speak for the others, but I know I put in 3–5 hours a week on the class alone, and if only one person passed the test, I would still consider it time well spent.

I realize all this isn't very much, but if a club of eight members can do this, a club with 200 members should be able to do at least twice as much.

Richard L. Collins WB4DBV, Camilla GA I thought I'd write you about these two stacks of magazines I have. One stack sits so nice on the shelf, and the other is a job to get organized. The one that sits so nice is *QST*, and the other is your *73*. Why? Now after many long hours of deep thought, I've found the answer. The *QST* is read once, and the *73s* are read and re-read many times over. Keep up the good work. TNX fer a great magazine.

Thanks for taking the time to write—and glad you're enjoying 73.... Wayne

Martin E. McCoy WB8TCZ/7, Cheyenne WY The last "new" magazine I subscribed to was some Timex/Sinclair rag that sent me two issues, then promptly disappeared from the planet. I'm not worried, though. You seem to have a knack for doing things right!

I'm signing up for your new magazine, and if it looks good, I'd like to get a subscription for High School III. High School III is an alternative high school here for kids who aren't able to remain in a "traditional" high school. I've visited HS3, and they look like a great bunch of kids who are making the best of what they have.

Their library is very pitiful—there is no Dewy Decimal 621 section (electronics). I'm going to try to rectify that, and even try to introduce some of the students to ham radio. Wish me luck!! Looking forward to your new mag!

Steven Rosenberg KC6FYL, Sherman Oaks CA I just wanted to drop you a note to tell you how much I've been enjoying *73* lately. I upgraded to General a few months ago, and I moved to an apartment QTH. April's issue was great. I built Frank KB4ZGC's "Artificial RF Ground," and now wonder what I did without it. The simple construction projects are great. From the April and May issues alone I'll be busy building for some time to come—I'm getting ready to put the Color Burst Ether Duster together for some mountaintop QRP.

Thanks for paying attention to apartment ops with articles on indoor antennas. May's "Apartment Antennas: A Challenge," was very helpful. You're definitely improving *73*, and I hope you keep the technical articles coming. I'd love to see a home-brew SSB rig—call me a glutton for punishment.

I hope the new codeless Technician license will bring a new kind of ham to the local repeaters, as well as a bunch of computer types to packet who wouldn't take the plunge before. I'm looking forward to *Radio Fun*—I hope it can do the job and help get a whole lot more people licensed and on the bands.

Oh, I used an Uncle Wayne tape for only a couple of hours and I passed the 13 wpm with no trouble and virtually no study. I didn't think it would work, but it's almost subliminal. I couldn't copy anywhere near 100% on the 20 wpm tape, but when the exam came, it was like a walk in the park! I don't know quite how it worked, but it did.

Glad the code tape helped... look for you on 20m now ... Wayne

Bill Pitts KC4WJG, Troy AL Recently my interest in amateur radio was rekindled, and I made a firm decision to get my ticket. The war in the Persian Gulf made me realize that electronic communications are still important, and I wanted to be able to do anything I could to help.

I passed the tests and made Tech, but I want to tell you that most of the people who become interested don't get their licenses. They become discouraged and lose interest. I think I have a very good idea why.

I had to travel 50 miles to find a ham magazine (*73*, of course)... about a week [later] I got a list of clubs in the area that offered exams. With a Radio Shack Novice and Tech theory book, which I also had to travel 50 miles to find, I studied for three weeks. The ARRL test was not exactly streamlined (it took three hours), but I passed on the first try.

While waiting for my ticket to arrive, I located two other hams where I work. One had retired and wasn't very active on the air. He told me about the local club, and I attended the next meeting. Guess what—there was no program and no planned activities, however there was a good discussion on how well the military operators could copy code during WWII. When the time came for the next meeting, I went to where the first meeting had been, but no one else was there. The location had been changed, and they thought everyone knew about the change. I had left my phone number with the club president. Since I didn't have my license, I couldn't ask anyone on the air where the meeting was. I had met two prospective hams at the first meeting who were studying for their no-code tests. They didn't pass. I wonder if I will see them again.

I have been reading *73* since the November issue. I really enjoy your magazine. The first thing I read is the letters, and the second thing is your editorial. I have to agree with you. There are a lot of people in amateur radio who don't want things to change. They may be nice guys, but they are behind the times. Perhaps I am passing judgment too soon, but no one has invited me to see their shack. No one has offered to let me listen in when they go on the nets, or shown me how their rigs operate. Is ham radio a closed society, or is it possible that most of the older hams are simply unaware of the needs of new hams?

I'm not giving up. I'm studying for General right now. I'm also studying your magazine. I want to build at least some of my equipment. I work for an aircraft manufacturer in the electrical and avionics fields, and I work with VHF and UHF radio regularly. I also have worked with computer hardware and software for many years. I taught myself to program in several languages. I can't wait to try packet and some of the other digital modes. What I'm trying to say is that I'm not stupid, and I think I could make a significant contribution to the local club, but they don't seem to care if I or anyone else gets a good start. If you could publish some articles dealing with simple receivers and transmitters, and some of the accessories to help operate the shack, I'm sure it would be worthwhile. If the old-timers won't teach us what to do, maybe your magazine will.

Bill, maybe we should start publishing the names of rotten ham clubs who are doing all they can to hurt amateur radio. We could also publish the names and callsigns of the club officiers. Maybe we can shame them into doing something... or at least get them to resign and let someone with a pulse take their position. Congratulations on getting your license. Look for me on 10m.... David N1GPH

J. Frank Brumbaugh KB4ZGC, Buffalo NY All authors appreciate comments and requests for additional information about their published articles, but those requesting such information should think about the cost of postage—not just for the one letter they hope to receive, but to consider that a number of other hams have also written the author for information—and enclose an SASE as an act of courtesy. The author's time and talent go into these replies, which he is pleased to do free of charge—but please, don't expect him to pay your postage bill as well. An SASE will guarantee a reply. I am 70 years old, living on very inadequate social security checks, and just can't afford to pay postage for those hams who want something from me but who lack the courtesy to enclose an SASE. I do not like to disappoint anyone, but I have to be realistic.

*Thanks for the reminder, Frank. All writers appreciate an SASE—*a self-addressed, stamped envelope. *When no SASE is enclosed, many writers do not answer requests.... Linda KA1UKM*

Tom Spellman KB8EOG, Leetonia OH I must confess, I enjoy *73*! The features on the latest equipment, the well-done projects. I would like to see some sort of goof-proof projects designed to help you learn something, so I can get my three kids involved more. They are primed by the things they see me do with amateur radio, and I catch them thumbing through *73*. They do ask questions. Yes, there are young people interested in ham radio. Yes, the children are interested in computers, science, and space. The middle child, 13-year-old Heather, did a science fair project on OSCARs. We can keep the hobby growing with a bit of encouragement to these kids.

Keep blowing the whistle on those lead-bottomed foggies who wouldn't share a frequency with a youngster even if they knew they would lose it because it isn't used (220).

Paul KI4CH, Chattanooga TN Just wanted to let you know how much I like your magazine. What I like are the articles on how to build it yourself. One of my favorite columns is "Above and Beyond." I've been a ham for about 22 years and have been wanting to get into working with microwave. Another column I like is "ATV." I'm happy to see that you don't use over half of your magazine writing about contests. Keep it technical, how-to, build-it-yourself. 73

NEVER SAY DIE

Wayne Green W2NSD/1

License Fees?

First, thanks to all of you who sent me clippings from newspapers and magazines about the FCC's plans to auction off the spectrum to the highest bidders. Anyone like to guess what country starting with "J" will probably end up owning everything?

In line with this thought, the question of license fees for amateurs has reared its ugly head again. Yes, I know, the knee-jerk reaction is to fight furiously to keep getting the free ride we've been enjoying. After all, I can hear you trying to ask me seriously, don't we provide communications during emergencies? Yep, sure, sort of.

And don't we train people in technology so they'll be available during wartime? Come on, you don't really believe that old baloney, do you? We haven't been able to provide any useful fodder to the military since WWII, 50 years ago. Yes, we were extremely valuable then. But our ham gear today is so far behind in technology that it's pathetic. We're generations behind and falling further back every year. Heck, we've still got some old coots who honestly believe that CW still lives. Talk about fossils!

Heck, if any Gulf War communications equipment comes onto the surplus market, most of us wouldn't have a clue about what to do with it. What are you going to do with spread spectrum surface mount technology microprocessor controlled radios?

Let's not try and use bluster and exaggeration to keep from paying our share this time. In fact, I suggest we go the other way and not just endorse the idea of license fees, but ask the FCC for even higher fees than have been suggested.

Higher fees? The man's gone daft in his dotage. Hams pay money? Everyone knows hams are the cheapest, most miserly group yet to appear on this old earth. Every ham knows that hams long ago won the concept of cheap away from the Scots. I'm exaggerating? Oh yeah? Ask any ham dealer how much I'm exaggerating. Any of 'em. You'll hear war stories you won't believe of cheapness gone berserk. We're talking world class cheap. We're talking hams who will spend three days shuttling between ham dealers at Dayton to drive the price of a new rig down another two dollars.

Wayne's Proposal

Look, since several of you have begun to notice the lack of youngsters in our hobby, and I think that most of us will agree that socking a young newcomer with a high entry fee isn't too clever, I propose that we ask the FCC to not charge hams under 21 any license fee. That make sense?

Yes, I know, the kids today are sporting $100 sneakers, even though they've never even learned to tie the laces. Perhaps we should encourage "Sesame Street" to do a special on shoelaces.

And I see their expensive designer jeans (with the knees torn out). And their Nintendo games. But if you stop and think about it, the kids with the most money are those running drugs and may not be exactly the kind of kids we're looking for. Even if they did get ham licenses we wouldn't understand them over the air since they speak some strange dialect made up largely of one 12-letter word.

The FCC, to simplify their tremendous work load (am I being sarcastic?), now deals out 10-year licenses. That's okay with me. Now I can forget to renew my license every 10 years instead of every five. But that tends to escalate any nominal yearly license fee into fairly large numbers.

I don't think any of us who are actually using our license would argue that we get $100 worth of enjoyment out of it a year. But lordy, that's $1,000 for 10 years. Holy moly! Panicsville.

A $3-a-year fee has been proposed. Well, since I'm suggesting that we let the kids in free, how about the rest of us ponying up a crummy $5 a year to make up for the difference? That's $50 for 10 years. That's about what a dinner for three costs if one person doesn't eat. Even cheapskates like me find a lunch for four goes over $50. Maybe it's the dessert that does it.

Even retirees should be able to eke out $50 for the privilege of irascibly driving the rest of us bananas with their endless exposing of the vacuity of their lives for the next 10 years.

Perhaps we should put in a proviso that our widows can apply for a refund for the unused portion of our fee in case we win our treasured Silent Key certificate before our license runs out. I had a letter from an XYL saying her husband had died that morning and she'd like a refund on his *73* subscription.

What to Do

This is the hard part. It means you've got to find someone you know who can write and get them to do some letters for you to sign urging the FCC and the appropriate senators and congressmen to make that a $50 fee for 10 years, with no fee for anyone under 21. I'd suggest you write the letters yourself, but I've been asking you to write to me for more than 30 years and I haven't heard from you yet, so it's obvious that . . . etc.

Of course I realize that, since you agree with me 100% of the time, there isn't any real urgency in your writing. After all, as long as I don't hear from you, I'll know that you are in total agreement with me. Right? Yes, I truly believe that. Nothing else makes any sense.

The FCC's Secretary gets mail at Washington DC 20554. Your senators and the senators on the subcommittee involved with this mess, Ernest Hollings (D-SC) Chairman, Daniel Inouye (D-HI), Dale Bumpers (D-AR), Frank Lautenburg (D-NJ), Jim Sasser (D-TN), Warren Rudman (R-NH), Ted Stevens (R-AK), Mark Hatfield (R-OR), Robert Kasten (R-WI), Senate Office Building, Washington DC 20510. Reps. Neal Smith (D-IA) Chairman, Bill Alexander (D-AR), Joseph Early (D-MA), Bob Carr (D-MI), Allan Mollohan (D-WV), Nancy Pelosi (D-CA), Hal Rogers (R-KY), Ralph Regula (R-OH), Jim Kolbe (R-AZ), House Office Building, Washington DC 20515.

The easy approach is to write your letter on a computer and then just change the salutation as you print it out for each senator or congressman. Oh yes, please run off an extra copy of your letter for me.

Living Longer

Lost some of your zest for amateur radio? Maybe it's time you got out of your old rusty rut and tried something new? Even the best of things get old after a while. Yes, even sex . . . unless you find a new partner. That seems to perk up even the oldest of codgers. It sure upsets their wives, though.

You know as well as I that it's having interests and goals that keep you alive. This is why so many men die shortly after retiring . . . retiring to enjoy their "golden years." Some gold. They should be called the wooden years, because that's the box they're in . . . or else a small vase on their widow's mantel.

Through *73* I can lead you to water, but I can't make you drink, no matter how much I hoarse around. Or hearse around. We can run articles telling you how much fun packet is, but we apparently can't get you to give it a try. Ditto slow-scan, RTTY, moonbounce, DXpeditioning, QRP, and so on.

Right now the biggest need our hobby has is not for you to keep yourself alive, mumbling inanities endlessly on 20m and begging for QSLs. It's to adopt a youngster and exercise your atrophied elmer muscles. We need a serious attack of mentoring.

Don't just sit there limp and jelly-like. Get some fire in your endocrine system. Call the principal of a local school and see if they have a program for people to come in and talk with their students. And if not, why in the hell not? Then go in and talk to the kids about amateur radio. Get 'em excited. And even better, offer to help 'em get their licenses.

We've got something over 400,000 licensed hams who seem to be at least partially alive . . . of which maybe half are even remotely active. I define "active" as being able to find a rig if pressed by a phalanx of steel-eyed, armed FCC inspectors.

It's no wonder we're seeing our ham bands being used more and more by criminals to make their operations easier. What's more secure these days than our ham bands? The Medford (MA) police (none of them hams) used 2m HTs to rob banks and stores. I guarantee we're not using our bands much. Heck, I take my 2m HT along when I travel and call in on every repeater I can find. I'll bet I get an answer on one out of 10. Phooey.

What little activity we have today seems to be concentrated in DX pileups on the low bands, where a couple dozen DXers spend their evenings jamming each other to get a QSL from some exciting place like London or Paris.

Lloyd and Iris are going strong, going from country to country on what seems to be a lifetime DXpedition. The only pity there is that they so seldom write to share their exciting adventures. The next time you work them, see if you can get in a couple words between your call and their signal report to suggest that they should at least take a few minutes a day to write something to help get kids interested in the hobby.

I've DXed from enough rare locations to know that every country visited holds a fascinating story. Did I tell you about my visit to Western Samoa, where I operated 5W1AZ? Did I tell you about how the natives will promptly kill you if you hit one of them with a car? And how they walk in difficult-to-dodge bunches down the middle of the only road on the island at night? Did I tell

QRX . . .

Packet Challenge

On January 25, 1991, the FCC sent violation of Part 97 notices to 11 amateur packet operators, fining several of them $300 for allowing the dissemination of a message allegedly posted by Joseph L. Reed WA3QNS of Norristown, Pennsylvania, on the N3LA/Rolf Jesperson BBS in Spring City, Pennsylvania.

The message publicized a 900 telephone number and urged readers to call the number to register opposition to the war in Iraq. The message did not mention a reported $10 charge for using the 900 number. Amateur operator Russell "TJ" Tjepkema of Virginia Beach, Virginia, believed the message was a business communication outlawed under Section 97.113(a), and reported the matter to the FCC in Norfolk, Virginia.

J. Jerry Freeman, FCC Engineer in Charge of the Norfolk field office, issued the citations "after consulting with many others." Until then, most amateurs believed that only the originator of a prohibited transmission was responsible for message content. Such is not the case, says Freeman: "...the amateur rules provide that the licensee of an amateur station shall be responsible for its proper operation.... Section 310(d) prohibits a radio station licensee from giving his or her license or any of the rights conveyed by the license, to anyone else...." Freeman emphasized that the FCC licenses individual amateur stations, not systems or networks, and that all amateur service rules apply to each amateur station even when it is operating as part of a system.

More than 50 petitions have been filed with the FCC, seeking clarification of responsibility for messages sent through digipeaters, packet bulletin boards, and voice repeaters. As of April 26, four had been formally accepted for commentary.

Packeteers and sysops of BBSs are worried that if every message has to be evaluated before transmission, it will mean the end of packet as we know it. Although Freeman has seemingly backed off a bit by canceling the fines—and In most cases dismissing the charges against BBS operators who have taken corrective action—some angry packeteers are seeking to oust Freeman from government employment.

Freeman W4JJ, an Extra Class amateur himself, says, "Amateur radio operators are very resourceful. As I said before, they may not abdicate their responsibilities, and I believe they will come up with a system which will be able to prohibit dissemination of unauthorized traffic." When asked about the negative effect having to manually evaluate each message for content would have on the amateur's ability to handle traffic, Freeman replied that, "An amateur who retransmits a business or prohibited message is violating the rules. If there is an emergency, their procedures could be changed...they could have various degrees of readiness." TNX *W5YI Report, Vol. 13, #9*, and *Westlink Report, Nos. 600* and *601*.

It's Official

Amateurs must be **off** 220–222 MHz by midnight, **UTC** on August 28. That's 8 p.m. Eastern Daylight Time on August 27. The FCC issued its final Report and Order in PR Docket 89-552 on April 29. At that time, it also adopted rules for the use of 220–222 by the Private Land Mobile Service.

Basically, the FCC has divided the 2 MHz slice of spectrum into 400 five kHz-wide slots to create 200 narrowband channels. Ten of these will be reserved for government use. UPS will be the main beneficiary of the new channels.

The Eastern VHF/UHF Society is having a "transition night QSO party," henceforth to be known as "The 220 QSY QSO Party" to mark this "ending and new beginning." It will be in two phases, two hours before and four hours after the change. For complete rules, send an SASE to the Eastern VHF/UHF Society, Thomas J. Kirby W1EJ, 1 Meadow Knoll, P.O. Box 455, Pelham, NH 03076. TNX *Westlink Report, No. 601, B-N-T Bulletin, Vol. 19 Issue 5*, and the Eastern VHF/UHF Society.

Recognition of PRB-1

The Florida Legislature passed HB-203/SB-598, reaffirming federal guidelines in PRB-1. Passage of this bill, which became law on April 28, makes Florida the first state in the nation to recognize PRB-1, the FCC's Private Radio Bureau declaratory "Memorandum Opinion and Order," issued on September 19, 1985. In part, PRB-1 states that "State and local regulation of a station antenna structure must not preclude amateur service communications. Rather, it must reasonably accommodate such communications, and must constitute the minimum practicable regulation to accomplish the state or local authority's legitimate purpose."

Section 166.0453 of the Florida bill covers amateur radio antennas. It forbids local governments to enact unduly restrictive antenna ordinances that do not conform to the limited pre-emption titled "Amateur Radio Pre-emption, 101 FCC 2d 952 (1985)," also known as PRB-1.

ARRL Northern Florida Section Manager Rudy Hubbard WA4PUP originated the idea of pushing for a state law recognizing PRB-1. ARRL State Government Liaison John Hills KC4N of Tallahassee pursued Rudy's idea of asking Hurly Rudd, a neighbor and legislator, to introduce HB-203 in the 1991 session. Many Florida hams wrote, phoned, or telegrammed their district representatives, while Southern Florida ARRL Section Manager Dick Hill WA4PFK and staff pushed hard, too.

Adding to the fervor was a prosecution in Orlando of a ham who violated a blanket 25-foot tower limit under a theretofore ignored Orange County ordinance passed in 1979. According to Rudy, officials held further action in abeyance pending the outcome of HB-203/SB-598.

While future antenna restrictions are not totally banned, local politicians will be slower to think of them in the future. The legislation does not affect private contracts, such as land covenants and deed restrictions. Home and land buyers should research such restrictions before closing on a sale. TNX *Balanced Modulator, Vol. XXVI, No. 5.* TNX also Jim McMillan for sending us an early article on the proceedings. Referenced also was the ARRL's *FCC Rule Book*.

Bigger and Better

The best guess is that well over 35,000 people attended the 1991 Dayton Hamvention. The official attendance was 32,716, which didn't include several thousand youngsters who were admitted free to introduce them to amateur radio. That this 40th edition was bigger and better than ever—12% larger than last year—is a good indication that amateur radio is indeed alive and thriving.

More than $110,000 in prizes was donated by the amateur industry and awarded to lucky ticket stub holders. There was a separate prize drawing for the young people who were admitted free. One conventioneer won an ICOM IC-2SAT in an unusual way: He turned in $1,700 that he found in a folder with no identification. Earlier, however, the money had been reported as lost. Though it wasn't ICOM who lost the money, the firm wished to applaud WA8OKA for his honesty.

The first Hamvention took place in 1951 at the Dayton Biltmore Hotel. Six hundred people showed up to inspect the wares of seven exhibitors and to attend six forums. This is a far cry from 1991's three hundred plus exhibitors and 51 forums on diverse subjects.

In 1964 the Hamvention moved to Hara Arena, where it has been held ever since. New this year were large tent-booths for flea market dealers who couldn't obtain a commercial booth inside the center. Even though there were more sellers than ever, it was a sell-out. TNX *W5YI Report, Vol. 13, Issue #10.*

Help Save Our Bands

Write your congressmen in support of H.R. 73, the Amateur Radio Spectrum Protection Act of 1991. Introduced by Congressman Jim Cooper of Tennessee, a member of the House Committee on Energy and Commerce, this amendment to the Communications Act of 1934 would help prevent further

QRX . . .

Photo A. One of the most frequently heard voices in the Milwaukee, Wisconsin, area is that of Theodore Maddox WA9QQJ, recipient of a Good Guy Citation for his work with Novices. You may have heard him handling traffic when he was active with Navy MARS, too, call N0HEL. After the Navy, Ted joined a CBer's club in order to teach ham radio to CBers, which he did with great success. We salute Ted for his contribution to ham radio.

loss of our amateur radio spectrum. (See the March "QRX" for more details if you wish.) Tell your Congressmen that Jim Cooper has authored H.R. 73 to prevent further erosion of frequencies allocated to the Amateur Radio Service. You might mention that there are nearly half a million hams nationwide. Include the number of hams in your county or state, since this means potential votes. TNX Art Smith W6INI and *Counterpoise, Vol. XXXIII, No. 5.* Excerpt from article.

News from *Mir*

To help expand manned amateur radio in space activities, ICOM and PacComm recently donated gear to the Soviet space station *Mir*. According to Soviet amateur radio space operations coordinator Boris Stepanov UW3AX, the ICOM IC-228 2 meter FM transceiver and the PacComm "Handi Packet" TNC unit are already in orbit.

British astronaut Helen Sharman is presently being briefed by UW3AX on *Mir* amateur equipment operation. At the date of this writing (May 16) she was expected to launch around May 18 and rendevous with *Mir* a couple of days later. Operating from *Mir*, she was to use the callsign GB1MIR/U. If all went as planned, by now Helen would have contacted nominated schools in the United Kingdom, giving the results of and observations on various experiments being conducted aboard *Mir*. Undoubtedly there will be future opportunities to listen in on the 144 MHz contacts. TNX *Westlink Report, Nos. 600* and *601;* and John A. Magliacane KD2BD, CompuServe Space News

Tiny Cameras

The size of a thumbnail? According to an article in the April 25, 1991 *Wall Street Journal*, researchers at Edinburgh University in Scotland have developed a single computer chip that incorporates all the circuitry needed for a video camera. It does both light sensing and signal processing. Even with the lens that fits on top of the chip, it is still only the size of a thumbnail. When they become available, they may cost as little as $40 each.

While the researchers only envision its use in automatic teller machines for security, other people see more exciting possibilities, such as baby monitors, picture telephones, bar code readers, robotic vision systems, rocketeering, ballooning, and yes—you guessed it—ham amateur television, or ATV. *TNX Miles Abernathy N5KOB.*

Calling Ham Scouts

If you've combined amateur radio with Boy Scout/Explorer activities, Hal Camlin W3QLP would like to hear from you. With the help of the Baltimore Area Council of Boy Scouts, he is writing a book, the *Scouting and Exploring Ham Radio Manual*. Write Hal Camlin W3QLP at BSA Post 73, 7506 Jacquill Road, Glen Burnie MD 21061-3812. TNX *W5YI Report*, Vol. 13, Issue #10.

Writers Wanted

Radio hobbyists who like to write, and writers who are radio hobbyists, are being sought by Tiare Publications. Tiare is interested in developing new titles in all areas of amateur radio. If interested, ask for a copy of the Tiare "want list" which is available for an SASE. TNX Tiare Publications, P.O. Box 493, Lake Geneva WI 53147.

Photo B. Five-year-old Veronica Harrington KC6TQR of Long Beach, California, passed her Novice exam last April. Currently, she's studying for her Technician upgrade so she can get on the local 2 meter kid's net. Veronica also enjoys 10 meter voice. Her mom, Ann N6YGP, and dad, Curt N5HMR, helped her learn code and theory. Her other interests are ghost stories and vintage horror films.

Micro ATV Transmitter

Can the Dick Tracy video wristwatch be far away?

by Mike Henkoski KC6CCC

Ever think about going pedestrian mobile with ATV from your shirt pocket? If so, here's a project that will enable you to do just that! Thanks to the availability of a new packaged oscillator produced by RF Monolithics, Inc., of Dallas, Texas, the dream has now become a reality.

Most non-synthesized methods of transmitter design for VHF and above require the use of frequency multiplier stages in conjunction with standard crystals. Physical limitations placed on the crystal are such that fundamental frequencies over 20 MHz are not practical, due to the fragile nature of the quartz wafer.

There is, however, another way of gaining higher oscillation frequency using the same quartz material: Use a SAW (Surface Acoustic Wave) resonator. A SAW resonator is formed by placing a pattern of metal reflectors on the surface of a quartz substrate. Using this method, oscillation will occur at much higher frequencies than by conventional means, and you'll be able to achieve fundamental frequencies of more than 1 GHz. This resonator, when combined with microchip technology, will provide a packaged oscillator capable of producing over 5 milliwatts of continuous output in the UHF 70cm ATV band.

Normally, the cost to engineer and produce this type of device would be prohibitive to the amateur radio community. However, as luck would have it, the ATV segment of our band in Germany is used for license-free devices such as car alarms, garage door openers, etc. In looking through the spec sheet from RFM, I noticed that one of the frequencies they produced for the European market was nearly right on top of the 434.00 MHz ATV frequency (see Photo B).

Because of the frequency involved, and the small size of the components used, this project may prove difficult for beginners. Use of SMD (Surface Mount Devices) helps to lessen the effects of stray inductance and capacitance, but the small overall size of the project may still be a real challenge. Some standard components were used in noncritical areas. The primary goal was to end up with a stable and reproducible design.

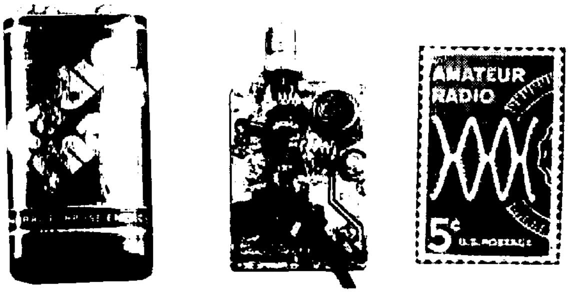

Photo A. The assembled micro TV transmitter.

A Few Tips About SMDs

You have to be able to see it to work with it—use of a magnifier of some sort may be helpful. Sharp tweezers are a must.

Use a small pencil-tip soldering iron with about a 35 watt rating. Make sure the tip is kept clean, and don't linger on the components too long.

When installing a component, tin the pad area lightly, position the component, then tack one side into place. Check the position, then solder the other side. Apply gentle downward force to the component to maintain position. *[Ed. Note: Before you tackle the micro ATV board, you may want to get a bag of SMD resistors from Radio Shack and try your hand at soldering a few practice components on a scrap piece of PC board.]*

Take your time. Fortunately, the parts count is not very high—I assembled the first unit in about two hours.

If you wish to etch your own board, remember that feedthrough positions are not all reflected on both halves; some are on one side, the remainder are on the other. Drill all the holes indicated on both sides independently.

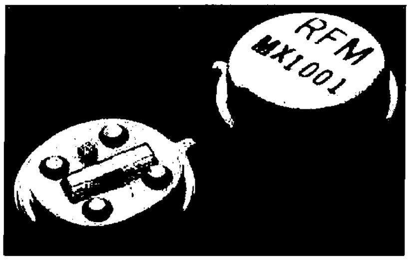

Photo B. The RF Monolithics SAW oscillator module. (Photo courtesy of RFM.)

The winding and placing of the coils require special attention. The closer the coils are made to the dimensions indicated, the easier the tune-up will be.

What Does What

The heart of the micro ATV transmitter is the Micro Transmitter Module by RFM. It consists of a SAW resonator, along with associated circuitry—all contained within a 5-lead TO-39 package.

The device has a maximum rating for the supply of no more than 10 volts, and a power output rated at +7 dBm, or 6 mW. *[Ed. Note: The micro-TV transmitter is designed to operate from a 9 volt battery (7–10 volt operating range). If you plan to use a power supply greater than 10 volts, you must use a voltage regulator IC to drop the voltage below 10 volts.]*

Pin 2 is provided for external modulation input, but for this project it is unusable because the maximum modulation rate allowable is 50 kHz. This pin is tied high through R1 and bypassed by C1. Pin 3 is available for power output adjustment. The value of R2 is set at 33k to allow maximum output power. Pin 4 is VCC with Pin 1, connected to the junction of L1 and C2, providing output tuning. C3 and C4 provide for proper RF bypassing of U1.

The output at L1 is coupled to the secondary L2 which feeds the base and bias network. C3 provides impedance matching to the base of the amplifier/modulator Q1.

Output to the antenna from Q1 is provided by way of matching network L3 and C4. L4, C5, C6 constitute a low-pass network ensuring adequate suppression of the 2nd harmonic (35 dB down). R5 lowers the Q of L3, which provides for greater stability of Q1 for changes in VSWR at the antenna. R5 also serves, together with C7, to block RF from entering the modulator. C10 through C13 provide additional bypassing of the power supply.

The modulator consists of R6 used to match R7 video gain control to the incoming video impedance of 75 ohms. If a 100 ohm value for R7 was available, R6 would not have been necessary, but it's difficult to find chip pots less than 500 ohms. C7 provides DC isolation and impedance matching to the base of video amplifier Q2 and pedestal clamp D1. Vari-

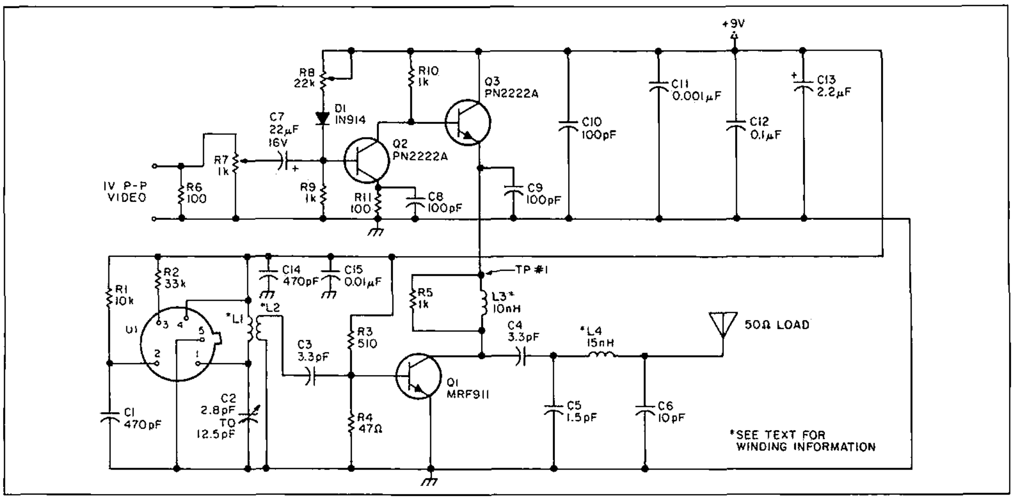

Figure 1. Schematic diagram of the micro TV transmitter.

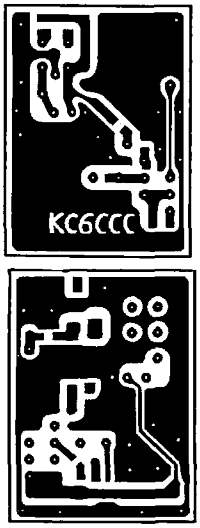

Figure 2. PC board foil patterns. (a). Bottom layer. (b). Top layer. Use a #74 size drill bit for all holes. Be sure to solder jumpers between the top and bottom layers where indicated for efficient grounding.

able resistor R8 sets the proper pedestal clamping and restores the DC level. Without clamping and DC restoration of the video waveform the sync pulse amplitude tends to change with variations of scene illumination. This has the undesirable effect of loss of sync and tearing of the picture.

Resistors R9, R10 and R11 provide proper bias and gain set for Q2. Capacitor C8 serves to boost the high frequency response of Q2 to allow for good resolution and color saturation. Transistor Q3 serves as an emitter follower modulator stage.

Transistor Q1 is run at only 25% of its maximum to ensure low intermod products and also to avoid compression of the horizontal sync. Heat-sinking is accomplished by contact with the PC board clad.

Coil Winding

Coil winding is simplified by using machine screws of the proper size and thread as forms. The wire used may be either insulated or not. I used 24 guage bare tinned wire (available from Radio Shack) on mine because you don't have to strip the coating. Wind each coil tightly on the form and bend the leads to shape while it's still on the form (to avoid distorting them).

Assembly

Install all SMD chip components first, caps and resistors. Then install transistor Q1, making sure to pre-trim the leads first. Leads only need to be about 1/16" long. The collector is the longer of the leads. When trimming to size, cut the collector at a slight angle to differentiate it from the others.

After prefitting the transistor onto the board, place a small amount of heatsink compound underneath. All that is needed is a 1/32" dot—too much may make soldering the leads more difficult than necessary.

Next, install all the coils, starting with L1. Solder L2 onto the ground plane on one side, then C3 at the other. The final position of L2 should be such that L1 and L2 appear to be one continuous coil as viewed from directly above. If the two are too far apart, there may not be enough coupling between them.

Install Diode D1, then transistor Q2. Now all the remaining components can be installed. Solder the battery clip leads to the board, observing the proper polarity. Use mini coax to connect the output to the antenna dummy resistor. Also use coax to connect to the video-in on the board. Connect the other side to the female RCA.

Tune-Up

Now we are ready for the final test and tuning, but before continuing use an ohmmeter to check the resistance of the circuit through the battery clip. It should be no less than 400 ohms. If it is, *stop now* and check for shorts.

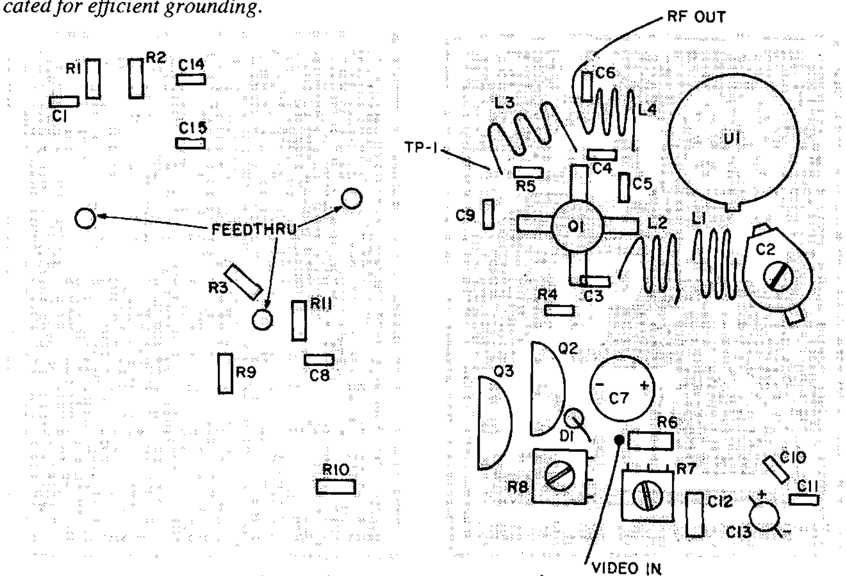

Figure 3. Parts placement: (a) Bottom side. (b) Top side.

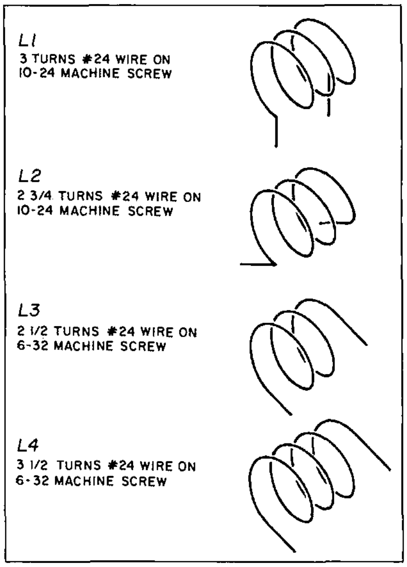

Figure 4. Coil winding details.

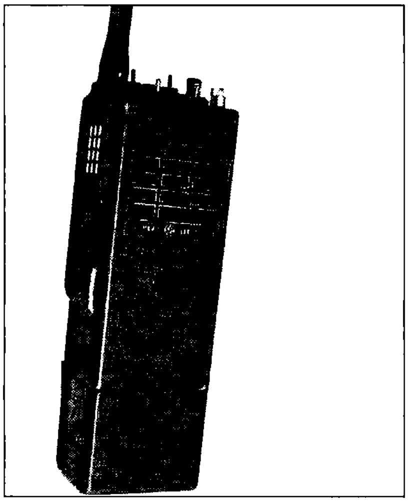

Photo C. Build your own "Lookie-Talkie". The micro ATV transmitter and a GBC CCD-100 or a Micro Video Products micro-TV camera can be easily mounted in an old 2 meter HT case. Note camera lens in center.

Connect a 47 ohm ¼ watt resistor with short leads (dummy load) between the antenna output and ground. Connect a standard 1 volt peak-to-peak video input. Connect an oscilloscope to TP-1, the modulation input to Q1. Apply power to the transmitter. Adjust pots R7 and R8 for 6.5 volts peak-to-peak video at TP-1. What we are trying to do at this point is set the waveform right between the positive rail and ground without compressing either the whites at the bottom or the horizontal sync at the top. The DC level at TP-1 should be approximately 3.3 volts with a 9-volt supply.

Next, adjust C2 to give maximum power output using an RF voltmeter placed across the dummy load. A standard DC voltmeter could be used to adjust the power out by inserting a 1N914 diode between the multimeter and the hot side of the dummy load resistor. Connect the anode of the diode to the load and the cathode to the plus lead of the meter. Adjust for the maximum voltage indication. An alternate method of adjustment would be to use a signal strength meter or wattmeter. Most wattmeters will give some sort of usable indication for peaking.

Remove the dummy load resistor and connect the transmitter to a 70cm antenna—I use an HT rubber duck from my handheld—and observe the picture. You may wish to make some minor adjustments to R7 and R8 at this point.

The peak power output (as indicated on a spectrum analyzer) has been between 80 and 100 mW at the horizontal sync tip. Remember, power meters don't indicate in the same manner, so power output as measured using a meter may be somewhat less. If you have a spectrum analyzer available, you can fine tune by expanding or compressing the coils. Be careful not to short the windings.

Note: Some parts of the country use 434.00 MHz as a repeater input. Please check with the ARRL repeater directory to see if there are any ATV repeaters that may be affected by your transmissions when operating ATV from R/C aircraft. Most ATVers use a 2 meter simplex frequency for coordination of activity. Some of the more common frequencies are: 144.34 (Midwest), 145.17 (Phoenix), 146.43 (West Coast) and 147.45 MHz (parts of Ohio). Check the local activity before you transmit so as not to interfere with other ATV transmissions. Also, other local ATVers will enjoy flying along with your R/C plane if you alert them. Test flights have shown that interference to even weak stations can be minimized by maintaining a distance of at least 15 miles from an ATV repeater.

There are many uses for the micro ATV transmitter. My favorite happens to be flying it in model aircraft. I have also taken one of these transmitters aloft using a kite, and I've even attached one to a model RC car. There have been numerous balloon launches using ATV as a payload. This micro package, used to drive an SAU4 brick-type power amp (such as a PC Electronics PA-5), would make a nice payload. You could also build your own "Lookie-Talkie". Mike WA6SVT put one in a 2 meter HT case along with a micro TV camera (see the Parts List for camera sources) and had a blast carrying it all over the Dayton hamfest (see Photo C). Bring along a pocket LCD TV and you now have instant 2-way video communications in a very compact and portable package. Have fun. ■

Parts List

Part	Description	
All resistors are surface mount type, ⅛ watt, 5%.		
R4	47Ω	Radio Shack 271-313
R6,R11	100Ω	Radio Shack 271-313
R3	510Ω	Mouser 260-511
R5,R9,R10	1kΩ	Radio Shack 271-313
R1	10kΩ	
R2	33kΩ	
R7	1kΩ surface mount pot.	Mouser 321-3100-1K
R8	22kΩ surface mount pot.	Mouser 321-3100-22K
L1-L4		See text for winding info
All capacitors are surface mount type NPO, 50 V unless otherwise specified.		
C5	1.5 pF	Mouser 140-CC501N1.5C
C3,C4	3.3 pF	Mouser 140-CC501N3.3C
C6	10 pF	Mouser 140-CC501N100D
C8,C9,C10	100 pF	Mouser 140-CC501N101J
C1,C14	470 pF	Mouser 140-CC501N471K
C11	0.001 µF	Mouser 140-CC501B102K
C15	0.01 µF	Mouser 140-CC501B103K
C12	0.1 µF	Mouser 140-CC502B104K
C2	2.8-12.5 pF trimmer	Mouser 24AA071
C13	2.2 µF, 16V tantalum	Radio Shack 272-1435
C7	22 µF, 16V tantalum	Radio Shack 272-1437
D1	1N914 diode	Radio Shack 276-1122
Q2,Q3	PN2222A NPN transistors	Mouser 592-PN2222A
Q1	MRF911 NPN transistor	RF Parts, Inc. or ECG63
U1	MX1020	SAW oscillator (RFM)
Misc. parts:		
2′	#24 solid wire	Radio Shack
1	9V battery clip	Radio Shack 270-325
	Mini coax RG-174 type 50Ω	Belden
1	Female RCA phono plug	
1	Female SMA connector (optional)	E.F. Johnson 142-0701-201 or equiv.

Kits or Assembled/Tested:

A complete kit including SAW oscillator, blank PC board and all components is available for $89 ppd. from Elktronics, 12536 TR 77, Findlay OH 45840. (419) 422-8206. Also available as separate items are the blank PC board ($19) and the 434 MHz SAW oscillator ($30).

Assembled and tested micro ATV transmitter boards (catalog #ATVM-70) are available for $119 from PC Electronics, 2522 Paxson Lane, Arcadia CA 91007. (818) 447-4565.

Please include your callsign with your order.

Tropo Time is Now!

Talk thousands of miles on the VHF/UHF bands.

by Gordon West WB6NOA

Hooking up with a repeater 300 miles away, direct, on FM, is often possible during the summer and fall months. If you own a VHF or UHF mobile or base unit with SSB capabilities, your long-range contacts on what are normally short-range frequencies can really get exciting. And if conditions are just right, you can access an FM repeater over a thousand miles away! Imagine that.

Photo A. The KH6HME beacon site at the 8200' level of Mauna Loa volcano, on the big island of Hawaii.

The phenomenon for long-range VHF/UHF and microwave DXing is called tropospheric ducting. But don't confuse "tropo" with E-layer skip (Es), which may only last for a few minutes on 2 meters. The latter is the result of ionospheric reflections from high altitude, densely ionized clouds caused by wind shears. Tropospheric ducting, created by temperature inversions, may last for days and sometimes even weeks.

Super Mirages

Picture the tropospheric duct as an inverted mirage that occurs in the atmosphere above us. You've all seen a mirage, where you look DOWN the road and see the shimmering blue sky refracted from ABOVE by the sharp boundary layer of hot air lying inches above the ground. In a tropospheric duct, a sharp boundary of hot air associated with a high pressure system sits above us, causing VHF and UHF signals to refract along the bottom side of this layer, which might hug the horizon for over 2,000 miles!

In rare instances recorded in Santa Barbara, California, and Key West, Florida, the tropospheric duct became so extensive that observers reported seeing distant land masses appearing upside down, shimmering, out at the horizon! This optical super-refraction is the same atmospheric phenomenon that lets you see the glow of the big city lights hundreds of miles away, and also lets you receive TV channels from three states away! This usually happens in summer and fall.

The VHF and microwave radio horizon is generally 4/3 the visual horizon. The slight bending, or refraction, of straight-line VHF/UHF and microwave frequencies is similar to the bending effect you see when you put a rod in a glass of water. The refractive index of water is different from the refractive index of air, however.

Under normal weather conditions, the radio refractive index of air, represented by the symbol "N" for "Normal," is slightly over 1 (more specifically, 1.000345 to 1.000300). Pressure decreases with height in a logarithmic manner at about 1 mb for every 10 m in altitude. Temperature decreases 20 degrees Fahrenheit for every mile of increasing altitude in the troposphere up to approximately 40,000 feet. Along with pressure and temperature dropping as altitude increases, water vapor content also drops. (This is what is meant by "normal weather conditions.") The air is very dry when you are up there in a jet, flying across the U.S.

Decreases in temperature and water vapor are what most affect extra long-range VHF/UHF and microwave DX. When the weatherman talks about a high pressure system settling in for a few days with an expected temperature inversion, get ready for the possibility of a major "bump" in the normally smooth refractive index. At about the thousand-foot level, the inversion causes the temperature to quickly increase instead of decrease, as would be normal; and water vapor content abruptly drops; the air gets dry as a bone inside this thin inversion layer.

An inversion layer strong enough to create a big DX tropo duct develops as part of a stationary high pressure system. The high pressure "cell" is characterized by air descending toward the surface of the earth. As the air begins to drop, it gets warm. They call this "subsidence." At about

Photo B. Paul Leib KH6HME inside the beacon shack ready to work long-haul VHF and UHF DX back to the mainland.

Continued from page 14

the 1,000 foot level within the high pressure air "fallout," surface winds—especially those cool moist winds associated with large water masses—keep the descending air from bottoming out on the surface of the earth (ocean or land mass). This creates a band of warm dry air associated with the high, "capping," cool moist air below it. If the winds are gentle, this inversion layer may extend for hundreds or sometimes thousands of miles, and VHF and UHF waves are caught up in it. It acts like a waveguide; the radio waves go and keep going, with almost no attenuation.

Bruce Eggers WA9NEW, an expert in the study of super refractivity, says, "In the Northern Hemisphere, there are two very permanent high pressure systems which combine all the parameters contributing to super refractivity and tropospheric ducting...the Pacific high to the north and east of Hawaii, and the East Coast of the U.S. where the Gulf Stream brings warm water north along the coast. And in the Southern Hemisphere, there are some interesting potential tropospheric ducts, from the most southern islands in the Pacific (Pitcairn) to Chile and Peru. There is also the path between St. Paul and Perth, over the Indian Ocean."

Experts agree it is relatively warm dry air, associated with a high pressure system over cool, moist air, which can trigger extra long VHF and UHF/microwave ranges. These same conditions may also occur behind cold fronts, and in advance of warm fronts, where propagation will occur at higher frequencies like microwaves, rather than VHF frequencies. This is because the frontal zone is just the right thickness, neither too high nor too low.

The most consistent summertime and fall record-breaking tropospheric duct occurs between California and Hawaii. The discovery of this yearly phenomena was confirmed on July 8, 1957, when John Chambers W6NLZ in California successfully contacted Ralph Thomas KH6UK on 2 meters, repeating the 2,540 mile haul on the 220 MHz band from two years before. Then Louis WB6NMT made the grade on 70 cm in the early '70s. In 1983, Chip Angle N6CA and Paul Lieb KH6HME made a record-breaking contact on the 1296 MHz band. Paul and Chip have set their sights on the microwaves beyond 1296 MHz, and who knows when the California/Hawaii duct may support two-way communications as high as 10 GHz?

But nothing is more important than knowing when the band is open. Even the very best tropospheric duct will be an absolute loser if the gangs in Hawaii and the mainland don't realize the band is open.

The California–Hawaii Duct

In the United States, automatic beacons of 100 watts or less, operating on VHF/UHF and microwave bands, assist in the detection of a long-haul duct. It takes an SSB transceiver to pick up these beacons. The most distant beacons heard are on the 8,200-foot slopes of Hawaii's 13,680-foot Mauna Loa, an active volcano.

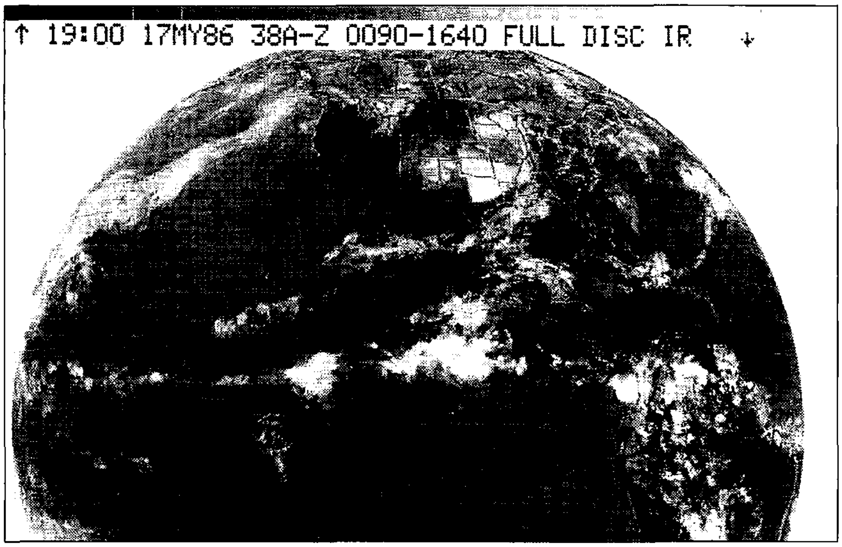

Photo D. A high pressure system sitting between California and Hawaii can be seen as a smooth haze on this satellite photo. A spectacular 1296 MHz opening occurred this day.

All beacons operate simultaneously in the CW mode, identifying KH6HME. The 2 meter beacon signals at 20 wpm, with a rise in the final steady tone by approximately 100 Hz. The 432 and 1296 MHz beacons operate at 13 wpm.

Hawaii ham Paul Lieb KH6HME is the main man at the beacon location. Hawaii television Channel 9 has allowed Paul and his beacons to occupy a metal building that's precariously perched on the side of the Mauna Loa volcano—a volcano that sees red hot lava activity just a few miles south of the beacon location!

Paul is alerted to the reception of the beacon signals by West Coast amateur radio operators. The beacons have been heard as far north as Oregon, and as far south as Mexico.

"When I get the phone call that the beacons are coming in, I pile all of my transceivers into the back of my station wagon, and take the one and a quarter hour drive from Hilo to the Mauna Loa beacon location. And as I go

KH6HME Beacon Characteristics

Beacon Location	19° 35'19" N; 155° 27'10" W
Elevation	8200 feet on the side of Mauna Loa volcano
6 meter beacon	50.061 MHz, 20 watts, 3-element beam, toward the mainland
2 meter beacon	144.170 MHz, 60 watts, into a pair of home-brew 7-element yagi (NBS) horizontal antennas
222 MHz band	No beacon, just two-way
70 cm beacon	432.075 MHz, 35 watts output, into a pair of long-boom horizontal yagis
ATV	434.000 MHz (on command, alternates with the CW beacon), 80 watts peak video output into a pair of K1FO beams.
900 MHz	two-way equipment
23 cm beacon	1296.000 MHz, into a stack of 4 loop yagis
Liaison frequency	28.885 MHz USB, 100 watts into full wave loop

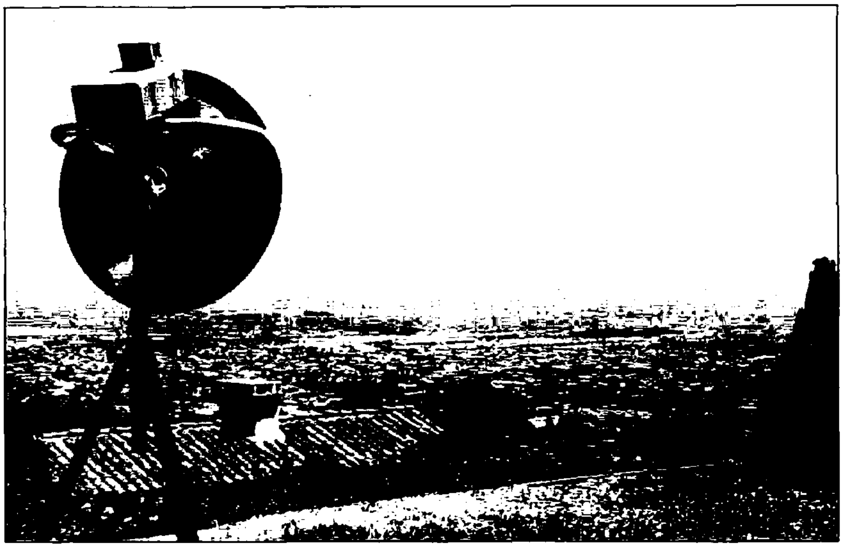

Photo E. *Will 10 GHz contacts be possible between California and Hawaii? (Author's setup at Palos Verdes, California, pointed towards Hawaii).*

up the mountain, passing through the different tropospheric levels, I can hear the mainland FM music broadcast stations get louder and louder," says Paul. He also gets the word out on the local repeater to Russ KH6FOO, Al KH6IAA, and Jack KH6CC, that tropo time has arrived. These operators give additional contacts to the mainland when the tropospheric duct gets low enough to their home locations.

"When I get to the site of the beacons, I can usually look out on fog and low clouds approximately 500 feet below our 8,200-foot elevation. The air is sometimes quite warm, and this tells me I'm right in the middle of the duct."

A New Challenge for ATVers

This year, Paul is trying a new mode of communications between Hawaii and California: amateur television at 434 MHz. Using PC Electronics' equipment, a Mirage 80 watt repeater amplifier custom-tuned by PC Electronics, and the Elktronics' video ID board, a new type of world record may soon be set for all ATVers to enjoy. FM signal strengths will need to peak well over S-9 in order for an ATV signal quality of P3 to be achieved, but in the past, 60 dB over S-9 narrowband FM signals have easily made the grade. According to Paul, "Sure, it can be done if the tropospheric layer achieves just the right thinness to trap the 434 MHz ATV signals."

If you are not equipped with an SSB transceiver, you can still make some long-range tropospheric duct contacts on FM. Between Texas and Florida, 25 watt FM rigs have sufficed. Just a few years ago, a widespread opening allowed mobiles in Boston to work mobile stations in Florida on 146.520 MHz FM! And most recently, FM hand-held contacts took place between Miami and Cuba—albeit both stations were using handhelds atop tall buildings. Nonetheless, the tropo duct allowed them to exceed FM handie-talkie range well beyond what could ever be expected under the best of conditions.

This summer, keep an eye on your television for signals from an outside antenna system showing up on normally unused channels. If you're on cable television, chances are the only way to detect a long-haul tropo duct is interference lines coming in over the master cable link receive station.

You can hear a tropospheric duct quite easily on your automobile or home FM stereo receiver. Once again, tune to frequencies not normally used in your area, and listen for distant stations. Same thing with your FM 2 meter and 432 transceivers—listen to repeaters coming in on frequencies that are normally absolutely vacant. Try programming repeaters over 200 miles away into your mobile, and wait for a hot, windless day to see whether or not you can pick them up.

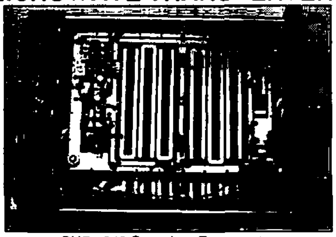
Every summer, long-haul tropospheric band openings occur to span distances well over 1,000 miles in the United States, and also between California and Hawaii. Sure, big directional antennas will give you the edge over smaller systems when the band opening is beginning to form, but once the tropo duct gets into full swing, almost any kind of VHF antenna should work the path well.

On FM, stay with vertical polarization. On sideband, most beacons and most DX stations operate horizontal. Cross-polarization within a duct could knock down signals by as much as 9 dB—so keep your antennas in the same plane.

Who knows what will happen with global warming, and with the warm ocean currents now beginning to form in areas that, normally, have been cool? This could be the best year ever for anyone with any type of VHF or UHF transceiver, including a handheld, to enjoy the excitement of long-haul DX tropospheric ducting.

You may contact Gordon West WB6NOA at 2414 College Dr., Costa Mesa CA 92626. Please include an SASE if you request information.

MICROWAVE TRANSVERTERS



SHF 1240 Complete Transverter

SHF SYSTEMS No tune linear transverters and transverter kits for 902, 1269, 1296, 2304, 2400, 3456 MHz. All use 2m i.f.@13.8V. Kits include mixer and L.O. P.C boards, xtal and all components. Built units include I.F./D.C. switchboard, connectors and compact low profile housing. Other frequency options in amateur band available.

DIGITAL VOICE RECORDER

VERY SIMPLE

Due to its advanced circuit design, the operation of the DVM-58C Digital Voice Recorder is as easy as 1-2-3.

1. Connect DC power source
2. Hook up a microphone
3. Start recording
(and, believe it or not, it's done!)

VERY USEFUL

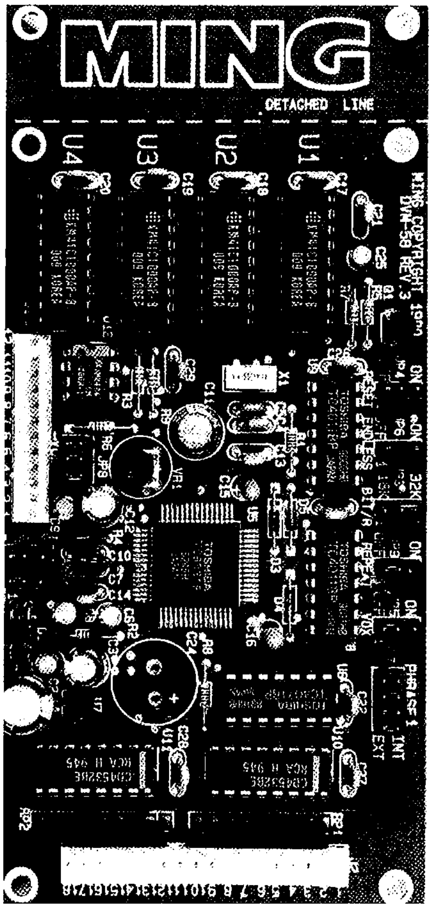
When you need something for your projects or any "Top Secret" invention, the DVM-58C is your best solution for all the followings:

1. Instant recording and playing, no rewind, no hassles.
2. Multiple message applications.
3. HAM radio communications.
4. CB radio communications.
5. Telephone applications.
6. Verbal instruction and warning systems

VERY ECONOMICAL

UNDER **$90**

with 1 Meg DRAM onboard.
(Additional DRAMs available at extra charge)



VERY POWERFUL

State-of-the-art technology & circuit design make the DVM-58C Digital Voice Recorder very powerful, compare following features:

- Very low standby current - only 8mA w/ 4 Mega DRAM.
- On board 0.5W audio amplifier w/ volume control (internal or external).
- ADM (Adaptive Delta Modulation).
- Selectable 16K/32K bps sampling rate.
- Memory expendable up to 4 Mega DRAM which gives you total of 2 minutes recording at 32K bps.
- Selectable "REPEAT" mode switch.
- 16 variable length messages each w/ direct triggering terminal enables you to play back any one of the messages at anytime you want -instantly.
- Selectable "VOX" automatically starts recording when you start talking.
- "AUTOMATIC RESET" simplifies single message recording operation.
- EOS (End of Sentence) output lets you control other device at end of the message in play back mode.
- "ENDLESS RECORDING" option allows continuous recording that can be stopped at any time to review past conversation.
- Reserved space for 0.1F/5.5V Gold Capacitor used for memory back-up system during short power failures.
- PCB dimensions 5.75" X 2.75" X 0.5".

Antennas by the Yard

HT antennas that really measure up!

by Ruston Cable WA6TLK

I wanted a rugged walkie-talkie antenna that would be tough, and also give me a little better performance than the standard rubber duck. This antenna is it. You can literally tie it in a knot without damage.

The required materials, shown in Photo A, are: an unpainted steel tape measure, binding post to male BNC or UHF adapter (Pomona P/N 3430 for BNC and P/N 1698 for UHF) and, not shown, some ½-inch PVC shrink tubing in the colors of your choice. *[Ed. note: If you can't find these adaptors at your local electronics store, they are available from Newark Electronics (312) 784-5100, P/N 35F1070 or 35F1069. Also Circuit Specialists (800) 528-1417, P/N 3430-0 or 3430-2.]*

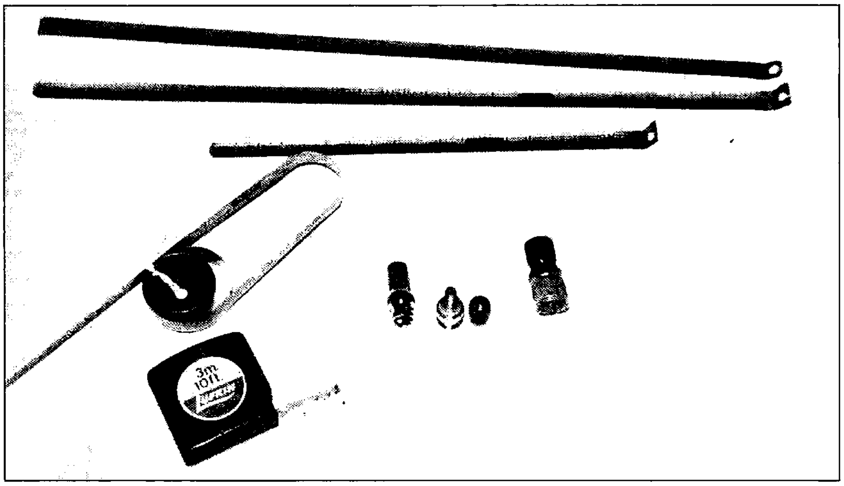

Photo A. Materials required.

Construction

If you haven't figured out what we are going to do yet, it's simple. Open up the housing of the tape measure, using whatever means is required. Inside you will find a nice roll of stainless steel antenna material, already marked off for you in inches, centimeters, feet, etc. Now, using whatever mathematical formula you like, calculate the length of tape needed for a quarter-wave length on the particular band for which you are making the antenna. Remember, these antennas can be made for any frequency: Civil Air Patrol, marine, MARS, scanner or aviation. I am using the amateur 2 meter band version for demonstration purposes. Construction for any other band is exactly the same.

Using a pair of scissors, I cut the length for the antenna to 21 inches. Remember to cut yours longer than calculated because it's a lot easier to cut the extra off than it is to add what you don't have. I then took a household ¼-inch paper punch and punched a hole near one end of the piece of tape (see Photo B). If you don't have an unpainted tape measure, now is the time to remove the paint from around the hole you just punched, using some fine, wet and dry sandpaper. This will insure a good electrical connection with the adapter. Also, trim off the corners on both ends of the tape using the scissors, then sand the ends to remove the sharp edges that are created from the cutting. Trust me, they are there and cut like a razor blade.

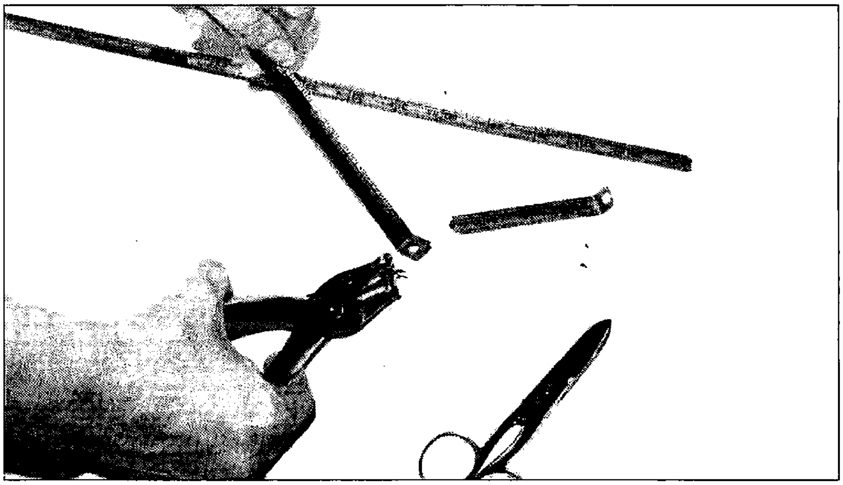

Photo B. Punch a ¼-inch hole near one end of the tape.

Now, the adapter. It doesn't matter if you're using the BNC or UHF adapter, the procedure is the same. First, remove the pretty-colored plastic-covered captive thumb nut. These thumb nuts are not intended to come off of the adapter under normal use, but they will if you use more then average force to unscrew them. If you have a really stuck one, use two pairs of small pliers and unscrew the thumb nut from the binding post.

You now have the two basic parts for the antenna. Run the binding post screw through the hole in the tape and screw the thumb nut back on as tightly as you can, using the pliers if necessary. Then, bend the steel tape flush up the side of the thumb nut. Put a piece of tape or rubber band around the antenna element and thumb nut to temporarily hold it in place. You now have an antenna ready to be trimmed to the desired frequency.

Tuning and Using the Antennas

To tune the antennas, I used a Bird Model--

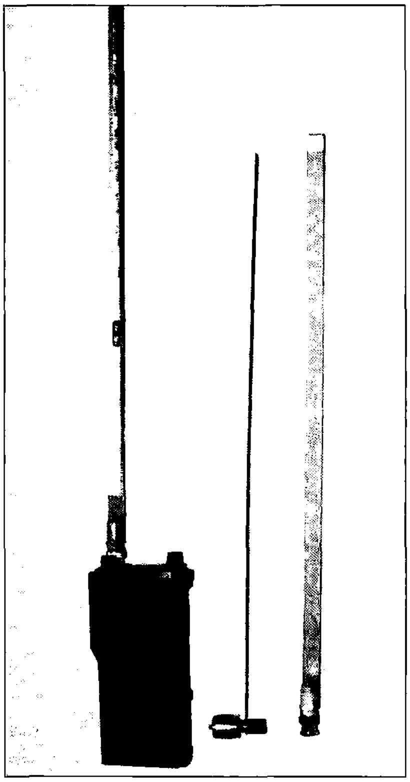

Photo C. The finished antennas.

43 thruline wattmeter and an ICOM 2 meter rig installed in the car. Use whatever setup you have to monitor the reflected power, VSWR or field strength. As shown in the picture, the actual trimming was done with my trusty scissors. The first reading on the Bird showed quite a bit of reflected power. And, knowing it was too long, I started cutting off ¼-inch pieces of tape from the top of the antenna until the reflected power started coming down toward zero. I then shaved off small pieces to get zero reflected power in the center of the band. The actual length turned out to be exactly 17 inches.

As a finishing touch, I offer two suggestions. Either cover the entire antenna with the PVC shrink tubing, or add just a small piece, about four inches, over the thumb nut area to hold the antenna element in the vertical position. The one with the small piece of PVC at the nut is a little more flexible, and lighter. It's your choice. It's best to use a heat gun to shrink the tubing over the antenna and connector. You can also use the hot burner of an electric stove as long as you keep in mind the PVC will melt and burn, so keep it from touching the hot element, but near enough to get good shrinking action. On the antenna that I covered completely with PVC, I added an extra piece of tubing over the thumb nut area to give it a little more rigidity and sturdiness in the base area.

That's it. After you make one, it takes about five minutes to make the next one. One option, if you want still more rigidity, is to put two or three antenna elements together and cover them all with the piece of PVC. I used three pieces of steel tape: one the length cut for least reflected power; the others one-third and one-half that length. This gives the antenna a tapered effect, with maximum flexibility toward the top of the antenna. No adverse effect was noted in the reflected power by the added layers of steel tape. The finished antennas are shown in Photo C.

Originally, I used these antennas to replace the rubber duck antennas on walkie-talkies and other radios that search-and-rescue ground teams use. These radios are configured as back-pack radios, freeing the hands of the person carrying them. These antennas will take the abuse of going through the woods, and they will spring back. When they do give out, they are easily duplicated.

I have found one problem with the antenna completely covered with PVC. If it is rolled up to fit in your shirt pocket, or some other small storage area, it will not unroll quickly. However, this problem occurred at −10° F. Keep this in mind if you expect to be hamming in cool weather. 73

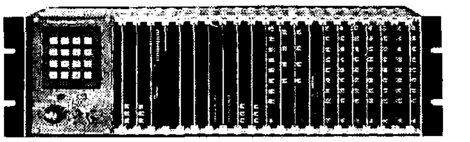
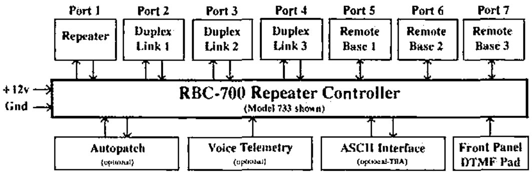
MULTIPLE REPEATER - LINK - REMOTE BASE CONTROLLER

Finally a controller that has solved control and audio interconnect problems between multiple radios. Your radio system can grow to multiple sites and stretch for hundreds of miles - and yet any radio can be fully controlled from any designated input.





The RBC-700 Repeater Controller is designed to support Repeater systems that require multiple radios connected together at a site. The RBC-700 utilizes a true 7 x 7 audio matrix switch which allows several conversations between ports at the same time. In the illustration above the 733 model is supporting a Repeater, 3 Duplexed Links to different sites, and 3 Remote Bases. Using simple commands, a user could tie the Repeater and a Remote Base to one Link, while the other Links are communicating through your site, holding separate conversations. Or, connect all of the ports together - like a big party line !!

Several models are available and are software configurable to support up to 3 Repeaters, 5 Duplexed Links, and 4 Remote Bases. A group or club can start with the basics and expand their controller anytime by simply adding boards and software. Free software upgrades for one year after delivery. Finally, a real controller for the Linked system operator !

Multiple Independent Repeater control	**Easy servicing**
Up to 5 Duplexed Links	**Intergrated Autopatch**
Up to 4 different Remotes	**Expand at any time**
Recorded Natural Speech Telemetry	**Programmable Scheduler**
Programmable Macros	**+10v to +14v Supply**
Connect / Disconnect multiple Ports	**Standard 5.25" Rack Mount**
Internal Receiver Squelch processing	**Card-Cage design**

The VOR-2 Video Operated Relay

P.C. Electronics
2522 Paxson Ln.
Arcadia CA 91007-8537
Price Class: $45.
Tel. (818) 447–4565

Control your ATV repeater with this versatile circuit.

About eight years ago the members of the Keystone VHF Club in York, Pennsylvania, decided to build an in-band ATV repeater (439.25 MHz in, 426.25 MHz out). We decided to add a UHF FM receiver from Hamtronics for center carrier audio detection. Most importantly, the receiver would pick off the necessary AGC voltage to drive the COR (Carrier Operated Relay), which activated the repeater exciter upon receiving a signal.

Upon completion of our repeater, our worst problem was receiver desense. This manifested in two ways: interference on the transmitted video in the form of cross-hatching, and an inability of the center carrier FM receiver to properly drive the COR.

Using a spectrum analyzer and judicious tuning of the exciter and PA stages, John Shaffer W3SST eliminated all but a vestige of desense. However, we were never able to make the center carrier receiver drive the COR reliably. We had to come up with something else.

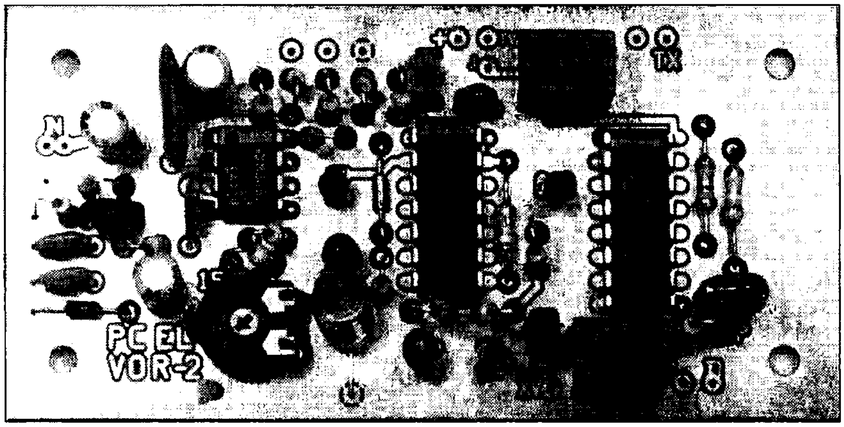

Photo. The P.C. Electronics VOR-2 Video Operated Relay.

The First VOR

When we began, there were no pre-packaged ATV repeater controllers. Builders of ATV repeaters had to use their ingenuity to obtain proper COR control, receiver "hang time," legal video ID, and the like. I decided to use my knowledge of TTL logic to design a complete ATV repeater controller.

Building the timers, relay drivers, and video switching circuits went quite well. I decided to get rid of the center carrier receiver COR and opt for a system driven by the detection of horizontal sync on the video carrier.

In theory, this would be much more immune to "falsing" and desense than the previous system. The heart of this system was a VOR (Video Operated Relay) board manufactured by PC Electronics in Arcadia, California. This circuit was designed around a NE567 PLL chip tuned to lock on 15.750 kHz. It was connected to the video output of the repeater receiver, and upon receipt of a bona fide ATV signal, would drive a relay and key the repeater exciter.

Initial tests were quite promising. When a strong ATV signal came on-line, the VOR worked perfectly. When the signals got weak (P2 or less), or the transmitting station did not have the correct sync to video ratio, the system would drop out. Since the video waveform is quite complex, the original VOR did not always "see" sync when the signal was weak (mixed with noise) or clipped (distorted/low in amplitude).

This first controller and the repeater functioned well under most conditions, however, and we lived with this system for several years.

The VOR-2

Recently, the club decided to build a cross-band ATV repeater (439.25 MHz in/923.25 MHz out). All components were purchased from P.C. Electronics in Arcadia, California. As I started to design a new controller, I noticed an interesting product offered by P.C. Electronics: the VOR-2 Video Operated Relay.

The VOR-2 senses horizontal sync, locks on it, and picks up a relay. It is also designed around the NE567 PLL. There are many substantial improvements and additions to the original VOR design, however. Baseband video from the receive system is connected to the input of the VOR-2. From here it is routed to a sync stripper where good clean horizontal sync is picked off and presented to the 567 PLL. THIS CIRCUIT WORKS WELL!

On our repeater it will key up very reliably on signals down to the level of P-0 (sync bars only!). The "lock on" frequency is adjustable, with an on-board trimpot. This should be set with a frequency counter connected to the appropriate test point with no video applied. The locking range is advertised as plus or minus 800 Hz.

Absolutely everyone who has tried can bring up our repeater, so I have no reason to doubt this. We have users running old monochrome line-frequency derived cameras, camcorders, computer generated graphics, and plain old lousy sync, and they all key the repeater equally well. There is also a built-in 10-second "hang time" to allow for repeater ID and to keep noisy or weak signals from dropping in and out. This delay is adjustable by changing the value of a resistor.

A Complete Repeater Controller

As well as providing excellent COR capabilities, the VOR-2 has virtually all the features of a complete ATV repeater controller. There are two relays on board the VOR-2. One keys the transmitter under control of the NE567 PLL, the other automatically switches the received video to the input of the transmitter when a valid video signal is present. This second relay also switches the exciter video input to an alternate video source during the 10-second hang time when no video carrier is present.

A video source such as a camera aimed at the repeater's callsign, computer graphics with the repeater's ID, or a video character generator/ID board such as the Elktronics VDG-1, will provide excellent and completely automatic video ID. If a video carrier is present

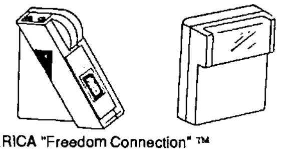
Wireless Remote Control For NINTENDO™ VIDEO SYSTEM

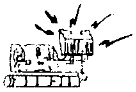


CAMERICA "Freedom Connection" ™
Turns your wired Nintendo™ control paddle into a remote control unit. Infrared remote like those used on TV's and VCR's eliminates messy wires. Allows players more mobility. Two players can use one remote unit except on games where they play simultaneously. In those games two "Freedom Connections" units are required. A well-known national discount toy chain sells these for more than twice our price. Operates on 4 AAA batteries (not included). CAT# IR-1 $9.95

HALL EFFECT SENSOR

Microswitch # SS41 - Tiny, solid state switch reacts instantly to proximity of magnetic field. Operates at extremely high speeds, up to 100 kHz. Case size: 0.12" X 0.17" X 0.06" thick. 4.5 Vdc to 24 Vdc supply voltage. 10 ma. sink type digital output. Operating gauss - 15 to 40. P.C. leads.
CAT # HESW-2 75¢ each • 10 for $6.50
100 for $60.00 • 1000 for $500.00

FLASH ASSEMBLY



This NEW compact flash assembly comes from a U.S. manufacturer of cameras. Unit operates on 3 Vdc and measures 2 1/2" X 1 1/4". Ideal for use as a strobe, warning light or attention getter. Complete with instruction on how to wire.
CAT# FSH-1 $3.75 each 10 for $35.00

SWITCHES

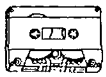
Mercury Tilt Switch

0.2" diameter X 0.65" long mercury tilt switch. S.P.S.T. Closes circuit when switch is tilted approx. 5 degrees.
CAT # MS-3 $1.00 each • 10 for $9.50 • 100 for $85.00

Rotary BCD Switch

EECO # 2310-02G - BCD 10 position rotary switch. DIP configuration fits in standard 8 pin I.C. socket. Right angle style. Screwdriver actuation. 0.42" cube. CAT# RDIP-2
$1.75 each • 10 for $16.00 • 100 for $145.00

HIGHEST QUALITY METAL C-60 CASSETTES (Erased)



Premium quality metal tape in C-60 cassettes (30 min. per side). One of the finest "brand-name" tapes on the market, in durable, clear plastic transport mechanisms. Recorded and bulk erased, the record-protect tabs have been removed and therefore, need to be taped over to re-record. Audiophiles will appreciate the wide dynamic range of this tape. If your cassette deck has a "metal" setting you will hear the difference. A real bargain!
CAT# C-60M $1.25 each • 10 for $10.00

for more than nine minutes on the repeater input, the VOR-2 will automatically switch to the second video source for about five seconds to meet the FCC's ID requirement. Both of these periods may be changed by changing the appropriate resistors on the VOR-2.

We have the VOR-2 and an Elktronics VDG-1 Video ID board packaged together in a Bud RF-proof mini-box in our repeater. Together they function as a complete ATV repeater controller in an area of about 7" x 4" x 2". We had only one problem with the VOR-2. Because the NE567 PLL COR is extremely sensitive, we had some very slight receive desense that caused the VOR-2 to lock on itself. This was cured by installing the VOR-2 in an RF-tight box, using feed-through capacitors on all inputs and outputs and an interdigital filter on the 439.25 MHz receive feedline, and keeping the receive and transmit antenna separation greater than 10 feet. This repeater has been in operation for over a year now with no other problems.

Other Uses

The VOR-2 can be used for applications other than repeater control. It may be used to activate a VCR whose input is set to the repeater output frequency (through a downconverter). The relays on the VOR-2 may be interfaced to the VCR to operate the record function when video is present. An interface could also be built to apply or remove AC power from the VCR if desired.

An inexpensive Sonalert may be purchased and energized when video from the repeater is present, which would be an excellent way to monitor activity when you're away from the shack. This would also be a good way to monitor security at your club site. In your shack, the VOR-2 could be used to energize your ATV equipment when video is detected from any video source. Finally, the VOR-2 could relieve you of remembering to video ID your station at the appropriate 10 minute intervals.

The documentation supplied with the VOR-2 consists of a single data sheet. Full schematics are included, as are suggested operating configurations. This is more than adequate, considering the ease of hooking up this circuit. Don't let the VOR-2's simplicity fool you, however. The VOR-2 coupled with some form of video ID generator fulfills all the requirements of a capable ATV repeater controller. 73

The Megaloop

Perfect for megalomaniacs.

by Stan Gibilisco W1GV

Have you ever wondered what would happen if you connected your HF transceiver via a transmatch to an infinitely longwire? Or to a wire 100 miles long? Or to a loop running all the way around the state line of, say, Kansas?

Most hams have heard old-timers tell stories of finding an unused telephone line a few miles long and using it as an antenna to work the world on a few watts.

A couple of years ago, following a serious accident, I returned to my parents' home to recuperate. I got on the air with the help of some old ham friends who donated time, muscle, and equipment. During that winter, I put up a longwire measuring 880 feet, and got great results. It was a good performer on all bands 80 through 10 meters, and wasn't bad on 160, either. Mel Larson KCØP had advised me to put up a longwire if there was any opportunity; he said I wouldn't regret it, and I didn't.

Nor do I regret my most recent experiment, a huge horizontal loop of wire that I call the megaloop.

A Far Out Concept

An infinitely longwire or loop, if either were possible, would have certain characteristics. First and most significant is that a change in frequency would make no difference whatsoever in the performance of the antenna in free space. It would have an infinite number of current loops, no matter what the wavelength of the signal applied to it. The impedance would be purely resistive; there would be no standing waves because no power could be reflected from the end of an endless antenna.

I've done some experiments that suggest that an antenna of about 50 wavelengths or more may be considered, in practice, infinitely long. As the electromagnetic field propagates from the feedpoint of such a longwire, the current and voltage loops diminish in magnitude the farther one gets from the station. See Figure 1(a). This is because the field radiates as it travels, and this radiation, along with ohmic loss in the wire itself, dissipates the signal. Even with a perfectly conductive wire, this effect would take place, solely because of the radiation resistance of free space. By the time the field has gone about 50 wavelengths, most of it is gone forever into the vacuum of space. If the longwire were a loop measuring, say, 100 wavelengths in circumference, you'd observe a similar effect. See Figure 1(b).

The vacant field to the north of my parents' house measured about 700' x 1200', the long way being east-west. In 1987-88, I ran the 880-foot longwire from the house to the west-northwest; in 1989, I ran a loop around as much of the field as I could manage. I don't know exactly what the circumference was, but it was probably about 3800 feet, or 0.7 miles.

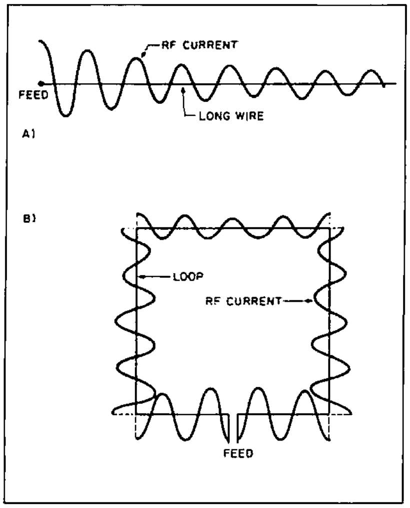

Figure 1. Current intensity diminishes as the electromagnetic field travels away from the feedpoint. (a) An antenna 50 wavelenghts long may, in practical terms, be considered infinite.... (b) A 100-wavelength loop with similar characteristics.

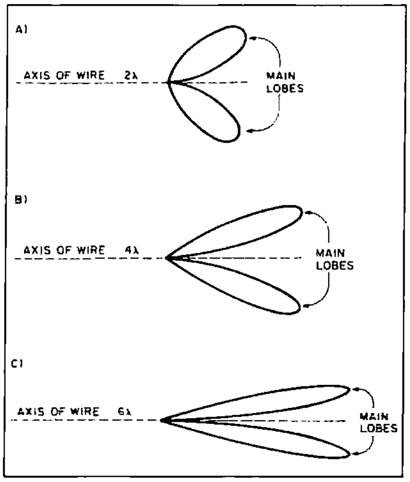

Figure 2. Main lobes for terminated longwires at different wavelengths.

Directional Effect

This is the second most important characteristic of an arbitrarily longwire. A large, strong lobe develops when a wire becomes more than a few wavelengths long. There is a limit to how much gain can be realized from this lobe. See Figure 2. This is because of the effect of radiation loss mentioned above; but certain long-wire configurations, like the terminated rhombic, can have around 30 dB of power gain relative to a half-wave dipole.

Minor lobes, now shown in Figure 2, also appear, and they become more numerous as the wire is made longer. An infinitely longwire would theoretically have infinitely many minor lobes. A wire 50 wavelengths long would have so many minor lobes that we might think of them as a single field; they would tend to blend together because of wire sag and ground effects from nearby objects.

Bending the wire into a loop might be expected to eliminate the directional effects and cause the minor lobes to more completely blend. The result would be a fairly uniform radiation pattern as long as the loop was small enough to allow some of the electromagnetic field to travel all the way around. A loop of infinite circumference, or many miles, would behave essentially as a straight longwire fed somewhere along its length and running off forever in opposite directions.

My loop was about 100 wavelengths at 10 meters, 50 wavelengths at 20 meters, and 25 wavelengths at 40 meters. Especially towards the top of the HF spectrum, the megaloop is like an infinitely long, straight wire. But at 80 and 160 meters, it is not so overwhelmingly large, and can be expected to have nearly omnidirectional characteristics. The polarization would be horizontal on all bands. The antenna height above ground would ideally be at least a quarter wavelength, or 33 feet at 7 MHz, 66 feet at 3.5 MHz, and 130 feet at 1.8 MHz. I was able to get most of the antenna up about 50 feet, the height of trees around the field. I got wires over the trees using kites of the inexpensive, dime-store variety (bat kites).

And the Third Characteristic...

Diversity! The antenna covers such a large area that if fading is taking place in one spot, reception may be good at another spot. This diversity effect is observed with all longwires or rhombics, and it works for the phasing type of fading, where different components of an incoming field arrive in phase some of the time, and out of phase some of the time.

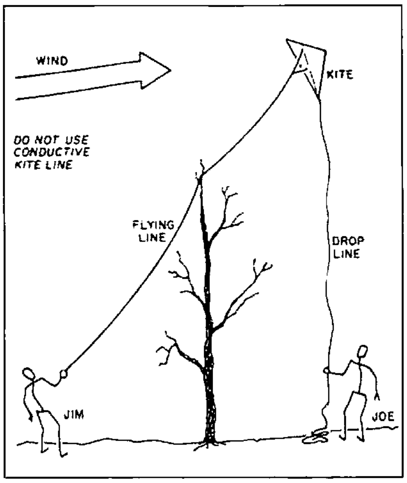

Figure 3. The kite technique works best with two people, so one can guide the flying line, and the other, the drop line. Only nonconductive line should be used for this operation.

Fading that occurs because of ionospheric absorption or a change in the maximum usable frequency (MUF) won't be reduced by diversity techniques. It's reasonable to expect that the diversity of the antenna would operate in transmit as well as in receive mode so that other stations would note less fading with the megaloop than with a small antenna such as a quarter-wave vertical, under conditions when multipath fading occurs.

The vacant field was scheduled for development, so the time was limited. I had to try out my idea of the megaloop during the winter of 1989–90, or never. This, plus the desire to grandly command the helm of such a device, motivated me to do it. Also, I hadn't heard much about anyone else having done it, though surely it has been tried before.

Materials

I used aluminum fence wire, Baygard®6 for the radiator. This six-strand wire, reinforced with nylon, is light and strong. It comes in rolls of a quarter-mile each. I bought three of these and used just about all of the wire for the megaloop.

With some nylon twine and a few old bat kites, I snagged the wires up in the trees, even though the wire is bare. In Minnesota, trees are fairly good insulators if it is below freezing. A good breeze, about 15 mph, facilitated the kite technique. See Figure 3. Also indispensable were warm mittens, as the temperature hovered around zero.

Feeding and Grounding

The megaloop can be fed in two ways. The preferable method is to bring the ends of the loop together into a parallel-wire line. See Figure 4(a). Then, to connect this line to the output of a transmatch equipped to deal with this kind of line.

If your transmatch does not have a two-wire line output, you may connect one end of the loop to the center conductor pin of the coaxial output, and the other end to chassis ground. See Figure 4(b).

Or you may leave one end of the loop free and connect the other to the center conductor pin or single-wire terminal. See Figure 4(c).

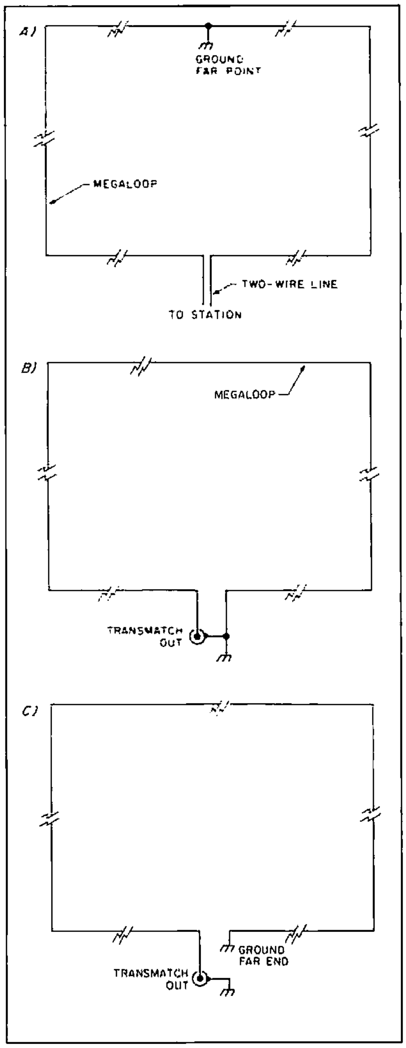

Figure 4. (a) Two-wire line is the preferred way to feed the antenna. (b) You can also feed the antenna with a transmatch having only single-wire or coaxial output. (c) An alternative method of coaxial feed.

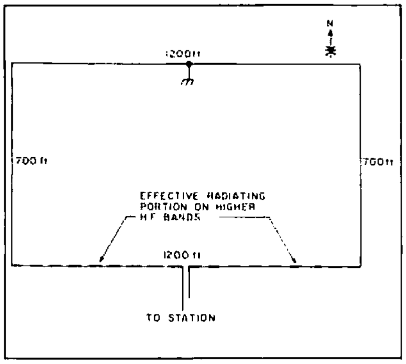

Figure 5. On the higher HF bands, only the southernmost leg of the loop at W1GV was really contributing to the radiation and reception in the megaloop antenna system. Nonetheless, the same basic advantages were realized.

In this case, the megaloop becomes a long wire bent into a circle.

I would recommend methods 4(a) or 4(b), but whichever method you use, a transmatch is necessary.

If the feed method at 4(b) is used, the loop is grounded for direct current, and this is good. Such a large antenna will develop electrostatic voltages because of atmospheric effects. It will actually be a hazard in or near thunder showers unless it is grounded for direct current. *Always, always disconnect the antenna from the rig when you are not on the air, winter or summer, storms or no storms. And never operate during thunder showers or lightning.*

With method 4(a), the loop should be grounded for direct current at a point opposite the station, or as nearly opposite as you can get. An eight-foot ground rod, driven into the earth well away from tree roots (copper can kill trees), and some buried radials, will ensure that you don't get clobbered when you touch the antenna wire. Some transmatches "ground" the antenna via the output of a two-wire feed balun. Do not rely on your transmatch for grounding, however, since some do not have this feature.

Putting It to the Test

Whatever theory may tell us, the way to decide how well an antenna works is to use it. Just because it will produce contacts does not mean that an antenna is a good radiator. I have worked stations over 1000 miles away by loading up a pair of ground rods spaced a quarter-wavelength on 20 meters. And you can work DX on a lightbulb.

Since I knew that a quarter-wave vertical with several radials is not a bad antenna, I compared the megaloop with a balloon-supported vertical on 40, 80, and 160 meters. A length of tubing was sufficient for a quarter-wave vertical on 20, 15, and 10 meters. (My radio doesn't cover the new WARC bands.)

The quarter-wave out-transmitted the megaloop on 160, and was comparable with the megaloop on 80 meters. Of course, that's no surprise. The megaloop did work better for close-in stations on 80; that may be attributed to the better high-angle radiation from the megaloop on this band.

As for reception, the megaloop was superior to the balloon vertical on 160 meters. The vertical was just too noisy. There was little difference on 80 meters, although some close-in stations were louder on the megaloop than on the vertical. The megaloop at W1GV was center-fed and grounded (marginally, because the earth was frozen) at the far side. This might be expected to reduce noise somewhat, along with the horizontal polarization and the comparatively low placement of the antenna (only 50 feet above the ground).

On 40 meters and above, verticals and the megaloop were just about equal for transmitted and received signal strength. This would be the expected result; both antennas are omnidirectional (essentially) and neither has any appreciable gain, except maybe on 10 and 15 meters. The feedpoint at W1GV was roughly in the middle of a long east-west run of wire,

Lightning Protection

Want some peace of mind?

by Frank A. Finger NU1A

We've all heard gruesome tales of damage caused by lightning. Many articles have been written about how to protect your valuable electronic equipment. All of the suggestions are valid, and if followed, will give some measure of protection. In this article, I'll cover some new methods as well as some of the accepted schemes. Anything to protect that expensive equipment is worth trying!

Believe It or Not

While reexamining one of my old physics books, I came across a formula for the discharge from a sphere. My attention was attracted to the following sentences. "It has been previously shown that the maximum charge that can be retained by a conductor in air is limited by the fact that the air itself becomes conducting at an electric intensity of about 3 x 10^6 volts per meter. $V_m = a \bullet E_m$. E_m is the maximum voltage; a, the radius of the sphere. For a sphere one centimeter in radius, E_m = 30,000 volts, and no amount of 'charging' can raise the potential of a sphere this size, in air, higher than 30,000 volts."

The implications of this are almost unbelievable.

Since the maximum potential at the sphere is directly proportional to the radius, suppose we make the radius very small? A pointed wire or rod is a sphere of very small radius. Now this pointed wire will discharge into air at a potential of a few hundred volts! This means that the area around the tip of the wire can not exceed a few hundred volts, and it will be impossible for a voltage buildup of the extremely high potential needed for a lightning strike. Boy, can we use something like that!

Automobile antennas used on cars in the early '30s were just a piece of hard wire mounted on an insulator. The wire would wipe electrons from the air, and as charges built up they would discharge into the air. The result was static. Using the above theory, an engineer came up with the idea of putting a small ball on the top. This increased the discharge potential so that discharges were no longer causing noise and we had quiet reception at last. Those little balls on the ends of our auto antennas are not just for decoration.

The Genesis of Lightning

As a thundercloud builds up, strong air currents form inside it, updrafts being the strongest. As particles of air pass particles of moisture, electrons are dislodged. In a short time, this creates large areas of negative charge and positive charge. Eventually, the voltage reaches the breakdown point, and lightning discharges the areas.

As the cloud moves across the sky, a charge of equal but opposite value follows along on the ground under the cloud, much like the shadow a low-flying airplane would make. When the charge builds to several million volts, we eventually have a lightning bolt, which discharges the area. Then it begins all over again.

As the ground charge passes under your tower, it charges up your tower and reduces the distance from the ground to the cloud by several tens of feet. If the charge reaches a critical value, we have lightning hitting your tower. The challenge is how to prevent this high charge buildup.

The Pointed Rod

Using the theory noted above, let's mount a very sharply pointed rod on a pipe extending above your beam or tower. Theory says the potential at the sharp point can not exceed a few hundred volts. This will NOT allow the charge to build up to the millions of volts needed for discharge. The result: no lightning strike! Why do you think they make lightning rods pointed? You guessed it—someone already thought of this, but failed to apply it to amateur radio! I am re-inventing the wheel, so to speak.

I live on a hill above a lake. I have two towers, the tallest being 60 feet. The beam support pipe sticks up another eight feet, and mounted to this is my sharply pointed rod. In 20 years I have never had a lightning hit, although trees around the neighborhood and some TV antenna towers have been hit.

The United States power squadrons say that you have a cone of protection spreading out from the point at about a 30 degree angle. Nice protection for the home and the trees in the yard.

Yes, theory really works.

Using Inductance

Often lightning strikes nearby, inducing large pulses of energy into nearby telephone and power lines. The large pulses find their way into our homes via the wires. Transistorized and integrated circuits are especially vulnerable. What can we do?

Again, let's go to theory. Remember the coil? It offers AC resistance called inductance. The lightning-induced pulses are half cycles of alternating voltage at very high frequencies, so a coil in the attachment cords should work quite well. Let's tie several plain knots in the cords and we have quite effective protection. Sounds silly, looks ugly as sin, but it works great.

I have seen receptacles blown out of the wall, and the equipment with knots in the cords undamaged. It works. Easy coils, I call them. The coiled cords on telephone handsets are good protection to a person talking on the phone during a thunderstorm. Lots of inductance there.

Those of us with computers and modems to the telephone line can protect our modems with knots in the cord, though it would be neater, and probably more effective, to wrap the cord a number of turns on a ferrite core.

At the base of your tower, it's a good idea to install a gas discharge tube in the coax line. Next, you can use inductance again by making a small coil of several turns in your coax cable, taping them in place with electrician's tape. It doesn't affect your RF energy. The coils impede the lightning pulse, and the gas discharge tube passes it to ground.

Of course, a good ground system will help immensely. Run a good ground wire from your tower to a good ground rod, then around your house to the telephone or power company ground rod. This wire buried under a few inches of earth will give a good ground. If you have several towers, adding a good ground wire to connect them all provides additional protection. I once asked an engineer how large a wire to use. He said, "The fatter the better." But I think a #6 or #8 guage wire gives reasonably good protection for the money.

A G.E. engineer discussing similar protection for their remote repeater sites on mountains said that measures like these probably provide about 90% protection. He said that someday the granddaddy of them all might come along and zap your installation, but the items suggested would be about as good as you can do.

Another suggestion was to run about two lengths of iron conduit up the tower leg and strap it tightly to the tower, then run the cables through the conduit. It will act as a one-turn short and prevent the pulses from propagating down the coax and into the house.

I never disconnect my radio equipment during storms, and I've never had any damage. It is nice to be able to so cheaply protect my equipment and home at such reasonable cost. A few knots, a pointed rod, a few feet of ground wire, and a couple pieces of pipe sure can give you peace of mind. 73

The Flight of STS-37

The first "all-ham" crew.

by Philip Chien KC4YER

The flight of STS-37 was a shuttle mission that seemed to be designed specifically for the amateur radio community. All five astronauts had their ham licenses, and the ham activities would include slow-scan, packet, and voice operations, and the first attempt to receive live television aboard the shuttle, plus—with some luck—a direct contact with the Soviet space station *Mir*. The mission would also include the deployment of one of the heaviest scientific spacecraft launched and the first post-*Challenger* spacewalk.

The *Atlantis* launch had originally been planned for November 1990, but hydrogen leaks in the main propulsion system delayed the launch until April 1991. The delay actually helped in one way: Pilot Ken Cameron KB5AWP convinced his fellow crewmembers (Commander) Steve Nagel, (and mission specialists) Jay Apt, and Linda Godwin to get their ham tickets, but (mission specialist) Jerry Ross was the hold out. Jerry promised the rest of the crew that if the launch delayed beyond November he would get his ticket, and when the launch was delayed he kept his promise and got his technician's license. The crew was extremely enthusiastic about the SAREX experiment, and Steve Nagel quipped, while introducing the crew, "Other crews may claim to have a ham or two aboard, but this is the first 'all ham' crew."

Pre-Launch Tests

To check out the SAREX hardware on *Atlantis*, Lou McFadin W5DID, an Aerospace Engineer at the Johnson Space Center (JSC), came to the Kennedy Space Center (KSC) along with Jerry Coles KB5ARA of JSC, John Stahler WB6DCN of Robot Research, Andy Bachler N9AB of the Motorola ARC, Schaumberg, Illinois, and Kai Siwiak KE4PT of Motorola, Ft. Lauderdale. KSC ham Mike Peacock KC4UGT loaned us his transceiver and helped us as a third hand and escort (see Photo E). (*Atlantis*'s hangar, the Orbiter Processing Facility, is considered a hazardous facility because of the poisonous fuels and high pressure gasses, and whenever anybody's in the building they have to be escorted by a trained person like Mike.)

While plenty of tests had been performed in the JSC shuttle simulators, a set of SAREX tests was planned for KSC using *Atlantis*'s flight hardware. These tests would verify the actual SAREX flight hardware in the identical configuration which the astronauts would use during their mission.

Photo A. Liftoff of the Atlantis. *Photos A-F courtesy of NASA.*

Photo B. Pilot Ken Cameron KB5AWP makes a voice contact while in orbit.

Preparing the orbiter for flight is always an extremely hectic activity with many different tasks going on at the same time. We set up the prototype ROBOT box, a Sony Camcorder, a Panasonic VHS VCR/monitor, a 2 meter transceiver, and a Grid computer—basically non-flight versions of the SAREX hardware—plus a fast-scan TV transmitter on a test table close to *Atlantis*'s crew cabin. Since we were just a couple of feet away from the orbiter and it wasn't going to move anywhere, we didn't need a tracking antenna. Our fast-scan TV antenna was a helical antenna mounted on a broom handle stuck into a vise.

It took about 90 minutes to get everything configured in *Atlantis* and on the workbench.

Photo C. Mission Specialist Jay Apt N5QWL with SAREX equipment at the ready.

Photo D. Mission Specialist Linda Godwin N5RAX prepares to make a few ham contacts.

Photo E. (l to r): Kai Siwiak KE4PT, Andy Bachler N9AB, Lou McFadin W5DID, John Stahler WB6DCN and Jerry Coles KB5ARA perform pre-launch tests of the SAREX hardware as KSC technician Renee Wolf looks on. On the workbench (l-r) the PGSC (Payload General Support Computer)—a modified Grid laptop computer, the SAREX ROBOT box, and the Panasonic VCR/monitor.

Everything was ready, and the voice, packet, and slow-scan tests went fine. We QSOed the shuttle from the ground using handheld 2 meter transceivers. The voice quality was excellent—but of course we were right next to the shuttle and didn't have to compete with anybody else! Technically, though, we could say that we had QSOed *Atlantis*'s SAREX—even though it was just a couple of feet away! We weren't able to complete the fast-scan TV tests due to a faulty test transmitter. It was determined that the ATV receiver in the orbiter was functional, however. After a final verification, the SAREX hardware was packed in its flight locker and shipped to KSC on March 21st and installed in *Atlantis*'s crew cabin.

Liftoff!

Atlantis's launch was planned for April 5, 1991, at 9:18 a.m. EST. Bad weather at the launch site, and range requirements, delayed the launch by 4 minutes and 45 seconds to 9:22:45 a.m. The ground shook and the skies roared as *Atlantis* took off on the 39th shuttle flight—just one week before the tenth anniversary of the first shuttle launch. Within three hours Ken opened up the middeck locker where the SAREX hardware was stowed and set up the rig next to his seat on *Atlantis*'s flight deck.

Atlantis was placed in a 28.5 degree inclined orbit to permit as much payload as possible, and was launched into a fairly high orbit (460 km or 243 nm.) to place the Gamma Ray Observatory as high as possible, permitting the longest possible lifetime. The high altitude increases the look angles for ground viewing stations, an extremely important issue for viewers at high latitudes. Since *Atlantis* was launched relatively early in the morning, most U.S. passes occurred during the daytime, much more convenient than STS-35's nighttime passes. However, with a planned five-day mission, STS-37 was the shortest SAREX flight to date.

As a secondary payload, SAREX only gets access to the orbiter's resources (including crew time) when it doesn't interfere with other operations. During the STS-35 Astro-1 mission last December, *Columbia* had to be pointed precisely to aim it at different objects in the sky. The continuous pointing resulted in relatively poor antenna angles. For STS-37, *Atlantis* was positioned for the best reception for many of the planned SAREX contacts.

School Contacts

NASA flies SAREX as part of its education program to help inform the public, especially students, about the space program. Consequently, the primary scheduled SAREX activities are pre-arranged contacts with schools. For STS-37, the schools were: Clear Creek independent school district, Houston, Texas; University School, Shaker Heights, Ohio; Discover Center Museum, Rockford, Illinois; Potter Jr. High School, Fallbrook, California; Hanover Elementary School, Bethlehem, Pennsylvania; several interconnected schools in southwest Oklahoma; Lyman High School, Longwood, Florida; Monroe Central School, Parker City, Indiana; Beaver Creek Elementary School, Dowington, Pennsylvania; and Reizenstein Middle School, Pittsburgh, Pennsylvania.

SAREX in the Future

NASA's current shuttle manifest does not show any official assignments for future SAREX flights, but there are several opportunities. AMSAT and the ARRL have asked NASA to fly SAREX on the STS-42 mission, currently scheduled for early 1992. On that mission the astronauts will operate the International Microgravity Laboratory (IML-1), a set of Spacelab microgravity experiments. IML will be launched into a high inclination orbit which will cover the Earth to 57.1 degrees north and south of the equator. The SAREX team is especially interested in flying high inclination missions to permit wider access to more hams around the world, especially U.S. hams in the central and northern latitudes. In addition, SAREX may fly on the STS-45 ATLAS-1 (ATmospheric Laboratory for Applied Sciences) mission in April 1992. It's likely that if schools continue expressing interests in participating in SAREX contacts, there will be more amateur operations aboard the shuttle in the future. The best way to let NASA know that there is interest in SAREX is to send letters to NASA's Education and Public Affairs departments at NASA Headquarters, Washington DC 20546. Letters to the ARRL and AMSAT are appreciated, but NASA needs to know that hams and teachers are interested in SAREX and the shuttle program.

If you're a teacher interested in participating in future SAREX missions, or know a teacher who may be interested, contact the ARRL at 225 Main St., Newington CT 06111. For the hams who cooperate with local schools, it's a rewarding activity and an excellent way to spend an afternoon (or evening or morning, depending on when it occurs). For the teacher it requires a fair amount of planning ahead of time, especially preparing the students and informing them about SAREX and the shuttle missions where you will be participating in. There can be frustrations—when the shuttle launch delays, when the encounters occur at inconvenient times (like during vacations or lunch time), when there isn't a high quality connection, etc. Everybody learns a lot even when things don't go perfectly, but when everything works—it's fantastic!

The Phone Bridge

To extend SAREX's capabilities to contact more schools outside of the flight path, the SAREX team uses a set of relay stations and phone bridges. The Figure shows how the phone bridge works for a typical school contact. The pre-arranged relay stations which communicate with the shuttle are located in Holtsville, California; Corpus Christi, Texas; and Ft. Myers, Florida. Other relay stations are located in Ecuador and Brazil for more southern orbits, and Australia for additional Australian school contacts. The relay stations use a phone network to conference call with SAREX control and a local ham contact close to the target school. The contact near the school patches the phone bridge into the local repeater, and the students talk on the repeater via a control operator located at the school. It's extremely complicated, and with five separate RF and hardwire segments there are occasional dropouts or weak connections.

Ask an Astronaut

The first STS-37 school contact was with students from Clear Creek independent school district who visited the Johnson Space Center and SAREX Control (see Photo F). As *Atlantis* came over his horizon, Ralph Warner N6MNN tried to contact the shuttle. It took several tries and about four minutes to get a good connection with Ken aboard *Atlantis*. The strength of the signal for this pass was fairly low, and the ground stations had to repeat the questions so Ken could understand them. As the orbiter went across the country, Bob Douglas W5GEL in Corpus Christi, Texas, and Don Carlson W4RDI in Ft. Myers, Florida, took over. All together, Ken and Commander Steve Nagel answered ten questions about their mission and training during *Atlantis*'s 19-minute pass.

I visited Lyman High School in Longwood, Florida, on flight day two to watch their attempt to talk to *Atlantis*'s crew (see Photo G). Joe Laughlin KC4UBY teaches a popular "Space, Technology, and Engineering" class and went all out for the SAREX contact. An essay contest determined which students would get to ask the astronauts questions. He took the lucky students to the Kennedy Space Center to see *Atlantis*'s launch on Friday.

The Lake Monroe Amateur Radio Society had set up their gear in Lyman's auditorium. John Rothert KC4IYO at the school contacted Joe Singer N4IPV at his home via the local repeater. Joe was connected via the phone patch with SAREX control and the relay stations.

For this pass, the California, Texas and Florida relay stations were used to relay questions from Potter Jr. High School and Monroe Central School, too. By the time SAREX control got to Lyman High School there was barely time for student José Lopez to ask Ken his question. Unfortunately, by the time Ken understood the question and started answering, *Atlantis* had passed over the Atlantic Ocean and out of range of the Ft. Myers relay station.

The next school contacts, an orbit later, went better. Ken talked with students at the Pennsylvania schools, and once again the last school didn't get a chance to get their question answered. Since the shuttle's orbit precesses to the west, the relay stations for that pass were Ted Jaramillo HC5K in Ecuador and Junior Torres DeCastro PY2BJO in São Paulo, Brazil. Ecuador wasn't able to connect to Ken successfully, but Junior was able to connect with Ken and patch in the students via the phone bridge.

We heard the good news just after that pass was completed. Since it had gone well, and the astronauts were willing, a backup pass would be used for Lyman High School and Reizenstein Middle School because we didn't get our questions answered! We immediately called the students who had gone home and told them to come back—they were going to get another chance!

As with the first time, Joe Singer called the phone bridge and we talked to him via the Lake Monroe repeater. We were hooked up with the relay stations over the phone bridge as the shuttle came over the horizon at Ecuador and everything was set. Then disaster struck—the repeater went down! Fortunately, the repeater came back up just in time

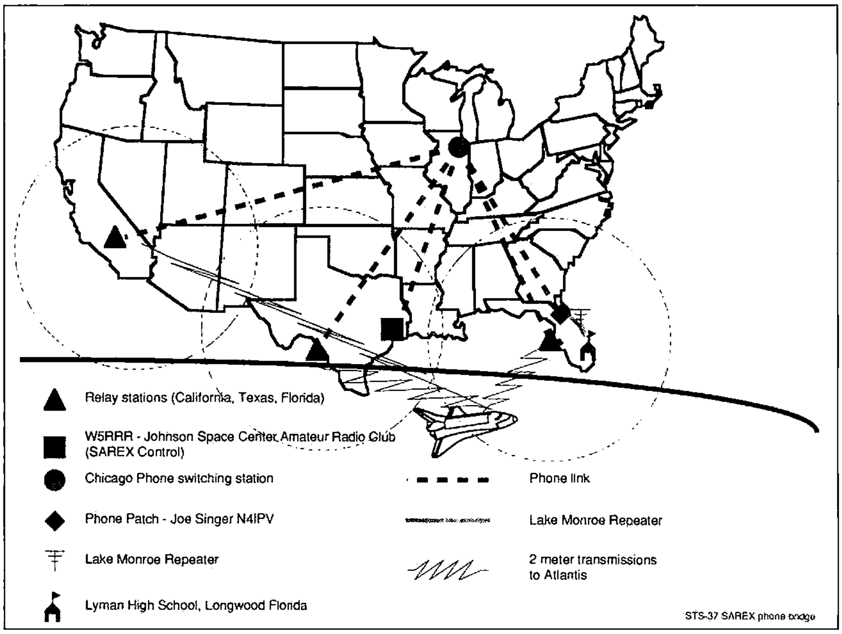

Figure. The intricate telephone bridge network made extended school contacts with the Atlantis a possibility thanks to relay stations located around the world. Figure by the author.

SAREX Comments From the Crew of STS-37 (from the Post-Landing Crew Press Conference)

Ken Cameron explained to us about the STS-37 attempts to contact *Mir*: "We had a couple of tries at contacting *Mir*. The ground had sent up messages letting us know when we had close passes, or what we call conjunctions. The closest was about 190 km. We called them repeatedly. There were arrangements for them to listen on a certain frequency. Unfortunately, there was still a lot of interference, probably due to other folks using their radios for other reasons on that frequency. We called them and we heard them calling us back. So, depending on your definition of real contact, I felt we contacted them. Certainly there were two small spacecraft up there orbiting the Earth, which were calling out for each other. That in itself is fairly significant—even if we didn't exchange words of great diplomatic importance. We were both up there, little points of light, and we tried to reach each other and share the view and share our thoughts. I really couldn't get an RST in the conventional sense—it was almost a one or a zero the way the radio was working. I heard Musa speaking English. I also heard over that area of the South Pacific what I thought at first was Russian, but I think it was just some other language that someone was transmitting in the area. I really couldn't tell. I tried Russian myself on Musa, but it probably didn't sound so red hot if they heard it. But I did my best after some college Russian classes. But Musa was speaking English."

Jerry Ross added: "We also did see *Mir* go across the sky just as the ground called up to us to look at the Big Dipper, and we poked our heads in all different windows and I was the first to spot it. Everybody else got a chance to see it, also."

Jay Apt said: "For all of us, it was a pretty profound experience to look up there and see the only other folks orbiting the planet, pretty close. I guess we were about 60 miles apart at the time. Just knowing that each spacecraft carrying its own world of oxygen and food was orbiting nearby and thinking to ourselves that that was pretty neat. And, there's probably never again going to be a time when men and women aren't continuously in orbit above our planet."

We asked Ken's crewmates how they felt about SAREX, and whether they would like to fly with it again.

Steve Nagel said: "Well, Ken was the 'primary ham,' as I called him. But I sure enjoyed the contacts I established. I had one where we talked to the students at Clear Lake here and I found that extremely enjoyable. I enjoyed having it on board. And Ken actually did manage the cables very well."

Linda Godwin said: "I think that all of us wish we had another day up there just to do more SAREX so we could have more time on the radio. I had one pass across Australia where I made some contacts, and one in New Zealand. It's kind of amazing that you're talking to the people down on the ground and you have a direct link with the folks down there you're seeing out through the windows. It's great."

Jerry Ross said, with a chuckle: "This was my first and ONLY two-way link on ham radio. So I have a very unique situation in the ham world."

Jay Apt said: "I felt privileged to be able to have direct contact with folks we were flying over. Jerry and I were talking one night about how neat it was to look down and think of all the cultures who were spread out below you and what those people were like, and I thought it was pretty neat to just have a way to talk to those people and learn about their cultures. I did talk to some folks in Australia and some folks in Hawaii, in addition to some of the school contacts we made. I think it's good for us to maintain some awareness that there's people on the ground different from you."

as Junior was about to complete his contact with the shuttle. SAREX control told us to ask our question and José and Jennifer McCarrick asked Ken questions about the Gamma Ray Observatory and how the body changes in space.

On the next day, when the astronauts woke up, they had several messages in their morning mail waiting for them in their TAGS (Text And Graphics System)—NASA's fancy term for a FAX machine. The SAREX sheet included "Thanks for going for the backup bridge on rev. 21. The kids at Reizenstein and Lyman were thrilled." That was an understatement!

All ten groups of U.S. schools were able to get through successfully during *Atlantis*'s flight. Unfortunately, everything didn't work as well as the school contacts. Several gremlins crawled into the system and the packet and slow-scan modes didn't work as well as predicted.

Packet and Slow-Scan TV

The packet and slow-scan television hardware is contained in the ROBOT box. The same box had flown with Tony England W0ORE on the Spacelab 2 mission in 1985 and was upgraded to add packet capabilities. Unfortunately, something happened between the last time the box was checked out on the ground and when the astronauts set it up in orbit, and the box would not work in its packet or slow-scan receive mode. Ground stations could hear the packet beacon and receive slow-scan pictures from the shuttle, but the astronauts couldn't receive slow-scan from the ground. The SAREX engineers thought that the problem was probably caused by a loose or broken cable and were anxious to get the hardware back so they could determine where the problem was and prevent it from happening again. *[Ed. Note: A broken*

wire in one of the cables was indeed the culprit!]

The astronauts still had the capability to transmit slow-scan pictures and sent many images of the crew cabin as well as the EVA activities. In addition, they made the best of the situation by spending more of their time in voice mode than originally planned.

Shuttle-*Mir* Contact

The Soviet *Mir* spacecraft was in an orbit which repeated around the earth at a similar rate to *Atlantis*'s orbit. While the two spacecraft were in widely separated orbits, they did pass close to each other on many occasions. The biggest problem preventing a ship-to-ship contact was crew schedules—both crews have to be available at the same time. During the STS-35 mission, *Columbia*'s crew tried to contact *Mir*, but the visiting *Mir* crew had just completed a docking and were shutting down systems on the ferry *Soyuz* spacecraft.

The most important technical problem is not the obvious one, the Doppler shift, but the relative velocities between the spacecraft. Since the spacecraft are in different orbits, they could be several thousand kilometers apart at one point, and a minute later be within a couple of kilometers of each other, and then thousands of kilometers apart in another minute. Besides limiting contacts to relatively short conversations, the antenna's pointing angles can be critical as the spacecrafts move relative to each other.

The most obvious problem for communications, language, was actually a non-problem. Musa Manarov U2MIR speaks English quite well and is extremely popular with hams around the world. On the U.S. side, while he hadn't used it in a while, Ken Cameron had studied a couple of years of Russian in college.

On the first flight day, Ken tried unsuccessfully to QSO *Mir*. The crew tried many times and did, at one point, hear the *Mir* cosmonauts. Musa (operating U2MIR) later confirmed hearing the *Atlantis* as well. This contact was the very first time that astronauts aboard a U.S. spacecraft had contacted cosmonauts aboard a Soviet spacecraft directly. (During Apollo-Soyuz, all radio communications between the spacecrafts were via their own ground stations.) Curiously enough, one of the first confirmations that Musa had heard *Atlantis* came from Ron Parise WA4SIR (who operated SAREX onboard the previous STS-35 mission), after talking to *Mir* from the Soviet mission control center he was visiting at the time!

Live Video Uplink

STS-37 was also the first attempt to receive live television aboard a U.S. spacecraft. Since *Apollo 7* in 1968, U.S. astronauts have sent back thousands of hours of inflight video, but have never seen broadcasts from the ground. The only monitors aboard the shuttle are closed circuit displays to monitor the shuttle's systems and on-board video cameras. During the *Spacelab 2* STS-51F flight, the astronauts got to see still frames for first time—via SAREX's slow-scan receiver. Until STS-37, no live television (fast-scan) had ever been received aboard a U.S. spacecraft.

Andy Bachler N9AB, a member of the Motorola Amateur Radio Club in Schaumburg, Illinois, developed the SAREX side-window-mounted antenna, and the fast-scan video hardware. Besides Andy's station, the other video uplink sites were Kai Siwiak KE4PT in Motorola, Ft. Lauderdale; Jim Steffen KC6A in Long Beach, California; and the Amateur Radio Clubs located at NASA's Goddard Spaceflight Center WA3NAN in Greenbelt, Maryland (using the U.S. Naval Academy's 40' dish in Annapolis), the Johnson Space Center W5RRR in Houston, Texas, and the Marshall Spaceflight Center WA4NZD in Huntsville, Alabama. The videos prepared for uplink included *Atlantis*'s launch, a videotape of the Gamma Ray Observatory's Payload Operations and Control Center at Goddard, and even an amateur video production.

During the first fast-scan uplink, *Atlantis* was not able to get a viewable picture, probably because of the orbiter's attitude. On the second and third attempts, the video uplink stations at Long Beach, Goddard, Marshall, and Schaumburg were able to uplink live video to the astronauts.

A Bonus Day

The deployment of the Gamma Ray Observatory and the spacewalk went fine, and *Atlantis*'s crew packed up their crew cabin to prepare for a landing on Wednesday April 10th. Unfortunately, the weather wasn't cooperating and the winds were too high. Flight controllers decided to keep the shuttle up for another day and wait for the weather to improve. There wasn't enough time to justify opening up most of the other experiments for just one more flight day, but the astronauts did take out the SAREX handheld transceiver and several cameras to take additional pictures of the earth. The bonus day resulted in *Atlantis*'s crew time being almost completely dedicated to amateur radio and unplanned QSOs! A couple of hams have kidded that SAREX got promoted from a secondary payload up to primary! Unfortunately for U.S. hams, the passes during that bonus day were primarily over South America and Africa. The next morning the crew was ready to come home again, and the weather cooperated. *Atlantis* landed at 6:55:29 AM PDT, 28 minutes short of a six day mission.

A Memorable Mission

During *Atlantis*'s 93 orbits, the five astronauts had talked with lots of hams and students around the world, received live video, and accomplished the first direct communications between a U.S. and a Soviet spacecraft. If they had only stayed up long enough for me to make a successful QSO (sigh)! 73

Software for the Ham Shack, Part III

Useful ham calculations you can program yourself!

by Bill Clarke WA4BLC

Another month has passed, and it's time for Part III in this series. By now you have become used to working with the formulas you added to the system last month. Using a computer for mathematical computations sure does make life easy.

Let's add a little more to the system. This month the MAIN MENU will grow to seven choices. Added will be:

6 - RADIO HORIZONS
7 - OHMS TO RESISTOR COLORS

Module Six

Figuring VHF/UHF ground waves is important when installing home and repeater antennas. The maximum usable distance for ground waves depends on the height of the antenna. This module asks for the antenna's height, then gives the maximum ground wave in miles. The figures are for flat terrain with the receiver at ground level.

Module Seven

Ever start a small project and list all the resistors you'll need, then have to stop and figure out the color codes? This handy module asks for the resistor value in ohms, then gives you the colors of the bands you will want to look for.

Entering the Listing

Before you add program lines from this month's listing, you must first LOAD "HAM2". After it's loaded, LIST it. Then you're ready to start typing. As before, don't worry if some of the lines appear out of order. The computer will straighten everything out.

Note modifications for the C-64 (see the listing).

After you have completed typing in all the lines, SAVE your work under the name HAM3.

Using the New Program

Load the new program by typing LOAD "HAM3" and pressing ENTER. When the computer signals READY on the screen, type RUN and press ENTER. This should be old hat by now.

The next thing you should see is the MAIN MENU for your new Ham System. It now shows seven selections: ANTENNA DESIGN MATH, TRANSMISSION LINE MATH, OHM'S LAW, POWER FORMULAS, EFFICIENCY FORMULA, RADIO

C-64 Modifications for HAM3

Don't forget about the modifications listed in Part 1 for C-64 users, and the following:

Replace the listed lines as follows:

```
610 INPUT "ANTENNA HEIGHT IN FT";H
616 PRINT "MAX HORIZ DISTANCE IS: "FNA(D)" MI"
731 PRINT "THE RESISTOR COLOR BANDS ARE:"
732 PRINT F$"/"S$"/"T$
```

Listing for HAM3

```

Program listing.

The Megaloop

Continued from page 30

and it might be expected that much of the electromagnetic field would radiate off along this part of the loop before reaching the parts running north-south. See Figure 5. I tried testing this directional effect, favoring east and west on 10 and 15 meters, but I didn't get any conclusive results.

The primary effect I was looking for was the diversity in the presence of multipath fading. This I did indeed observe, especially on the higher bands. But I wasn't surprised. Contacted stations reported less fading from my signal on the megaloop, compared to the verticals. I have experienced this advantage of geographically large antennas in the past, with the 880-foot long wire that I put up, and also with various kite-supported sloping longwires.

So what's the great advantage of a megaloop? For me, it was a chance to satisfy my megalomania, to do something before the real estate was no longer available. It was a temporary, wintertime antenna, and I'm glad my parents let me do all this experimenting there. I took the antenna down as soon as I had established that it worked; I didn't want this huge lightning attractor giving my mother anxiety all summer long. Now all that wire sits in the basement, awaiting some other grand project such as the 3/4 mile kite sloper . . . maybe. 73

by Dick Goodman WA3USG

SSTV with the Robot 1200C Scan Converter and the Martin Emmerson EPROM Version 4.0

Martin Emmerson G3OQD
6 Mount Hurst Rd.
Hayes, Bromley
Kent, England
Tel. (011) 44-81-462-4223
Price Class: EPROM Version 4.0, $140;
Crystal Oscillator Board, $60.
Cashier's check; Call or write for exact pricing.

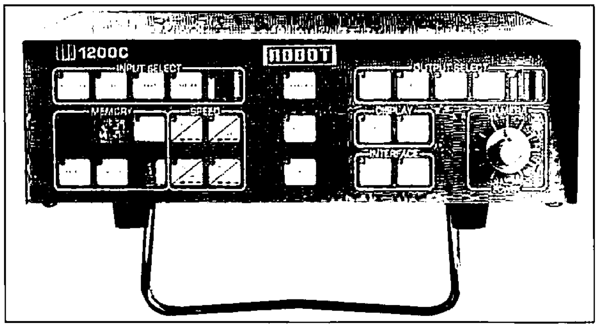

Photo A. The Robot 1200C scan converter.

Slow-scan television (SSTV) has evolved slowly but steadily in the last several years. Various transmission and reception standards have come and gone. Several companies have produced SSTV equipment and then disappeared from the scene. One company has been a mainstay in the field of SSTV: Robot Research of San Diego, California, manufacturer of the Robot 1200C scan converter (Photo A). While Robot's "bread and butter" is no longer in the amateur field, they still periodically schedule production runs of the 1200C.

Approximately three years ago, Ben Blish N4EJI (now AA7AS) created an SSTV system called the "Black Belt System," based on the Amiga 500/2000 computer. The Amiga Video Terminal (AVT) contains all current modes of SSTV, including those of Robot. It also includes its own special AVT protocol that proved superior to Robot. The complete AVT system is presently being marketed by AEA and is an excellent way to enter the wonderful world of SSTV. As new standards and protocols are developed, they may be easily incorporated into the AVT software.

There are other SSTV systems available. Research and development by other companies is moving at a dynamic pace, but at this time Robot and the AVT system are neck and neck in the forefront of SSTV technology. If there is an advantage of one system over the other, I would say it is in the field of marketing. The AVT system is being sold by AEA and other dealers. It has national advertising and support. Pick up a copy of virtually any amateur radio magazine and the AVT system will be advertised. Robot Research has limited exposure. The Robot 1200C is currently available from PC Electronics in Arcadia, California. Robot Research will also take orders directly at the factory.

With the impressive capability of the AVT system, its national exposure, and the ease of updates to the software, I felt that it was going to rapidly become the dominant SSTV format. Then Martin Emmerson G3OQD of Bromley, Kent, England, developed an updated EPROM for the Robot 1200C that incorporated virtually all existing SSTV modes including those used in the AVT system.

Robot 1200C Basics

The Robot 1200C scan converter is a complete, stand-alone SSTV system that requires only a video camera, radio transceiver, and television set (or video monitor) for operation. It does not require a computer. With these items, full color, high resolution pictures may be sent and received from virtually anywhere in the world.

Unfortunately, Robot decided not to support anything other than Robot modes of SSTV. This caused few problems when only Robot SSTV systems were available, but as time passed other systems were developed. An example of this is the Volker-Wrasse system used by European and other DX stations. This was incompatible with any Robot SSTV system, including the 1200C.

Even with these shortcomings, the Robot 1200C survived. While not as sophisticated as the AVT system, the Robot 1200C required very little additional equipment for its operation. It also contained a video digitizer that allowed grabbing full color frames from any video source. These frames may be stored in the Robot's internal memory and displayed on any television. The picture may also be transmitted, via the connected radio transceiver, anywhere that voice contact is possible. That's pretty impressive for a box about 11" x 4" x 12". The AVT system needs an Amiga computer along with the AVT SSTV hardware and software. If pictures from a video camera are to be sent, you must also get a video digitizer board and install it in the Amiga.

What makes the Robot 1200C incompatible with other SSTV systems is the program stored in its internal EPROM. But, this program could be rewritten to add other SSTV protocols, stored on a new EPROM, and put in place of the original Robot EPROM.

Modernizing the Robot 1200

The Martin Emmerson EPROM Version 4.0 (Photo B) contains all existing Robot modes

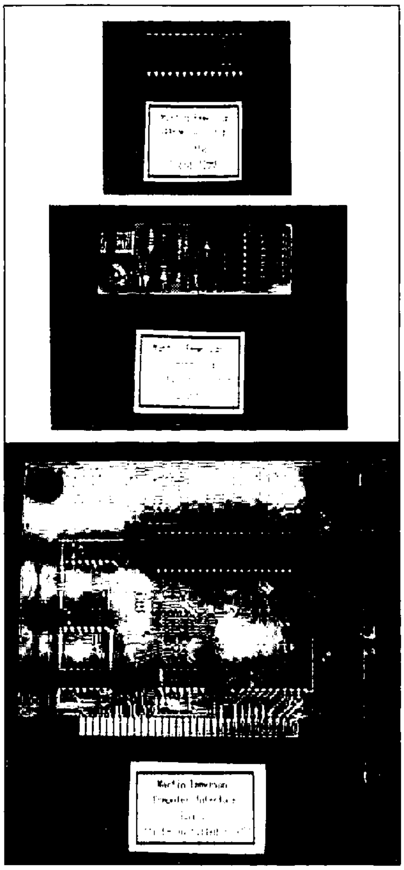

Photo B. The Martin Emmerson EPROM Version 4.0, crystal controlled oscillator board and the optional parallel port board for the IBM PC.

and virtually all current SSTV formats used anywhere in the world! Its additional features may be controlled from the front panel of the Robot 1200C, or operated remotely with enhanced features via computer control. It should be stressed, however, that a computer is *not* necessary to use any of the new SSTV modes.

To take advantage of all the features of the new EPROM, the Robot 1200C must be modified. The procedure is not difficult but, as with all Robot-related modifications, documentation is difficult to come by.

The procedure is basically threefold. First, unplug the original Robot EPROM and plug in the new Version 4.0 EPROM in its place. Second, install a crystal-controlled oscillator board (see Photo B). This involves removing a chip from the Robot, plugging the oscillator board into the empty socket, and placing the removed chip in a socket provided on the oscillator board. Third, replace all 64K memory chips in the Robot with 256K RAM ICs. This last modification also involves soldering a series of jumper wires to the Robot's motherboard, changing a jumper pin, and replacing an IC. Depending on the production run of the Robot, the IC may have to be unsoldered. The entire modification took me about two hours (I had to unsolder the IC).

Once the modification is complete, the Robot has the capability to store four high resolution color pictures in its internal memory (instead of one picture). This memory can also be used by Robot control programs (with an IBM compatible computer) for truly spectacular capabilities and special effects. More about this later.

The Emmerson EPROM

I ordered the Martin Emmerson EPROM directly from Mr. Emmerson in England. It took about six weeks to arrive as it was just coming out of beta testing. The EPROM is customized with your callsign, so it can be used only by the owner. It is apparent that Mr. Emmerson put quite a bit of effort into the development of the program on this EPROM. This "customizing" will prevent users from copying the EPROM and passing it on (unless you want others on the air displaying your callsign). I feel that the price for this chip is in line with what it will do.

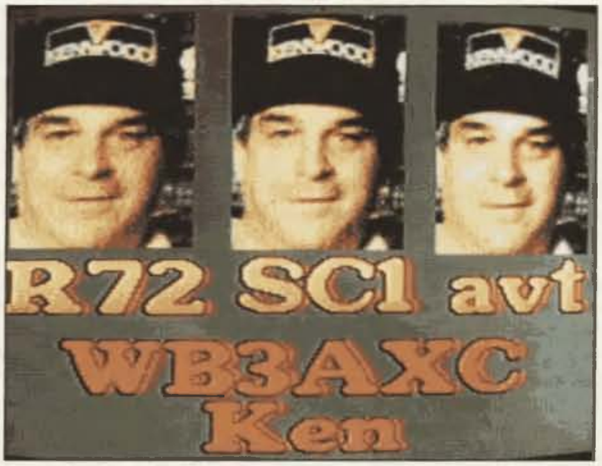

Photo C. Comparisons of Robot 72-second, Scottie SC1 and AVT 94-second pictures as received over a noisy UHF FM path. (This display and labelling was done with the Hi-Res 1.4 control program.)

Photo D. SSTV reception from Jim K4TGC on 14.233 MHz, using 36-second Robot protocol.

Photo E. WA3USG's family, transmitted on 2 meters and relayed back over a 35-mile path.

I also ordered the crystal oscillator board from Mr. Emmerson. The EPROM and oscillator board arrived intact from England, packaged ruggedly for shipment. The documentation provided is adequate. It consists of 12 high quality typewritten pages and several diagrams. Installation instructions are reasonably clear. If you have any questions, get on 14.230 or 14.233 MHz and holler for help. I can almost guarantee that during virtually any waking hour, there will be someone on frequency who has performed this modification! Instructions are also provided for replacing the 64K RAM with 256K chips.

What will the Martin Emmerson Version 4.0 EPROM do, once it is installed and all modifications are complete? All Robot modes are left completely intact and functional, and you will have many new ones. The four Scottie (SC-1) modes are used by many DX stations and US stations. It is not unusual to hear stations exchanging pictures, using the Scottie modes for hours at a time. It is interesting to compare the Robot modes with that of Scottie. In almost every instance, a picture received will look noticeably better when received via the Scottie mode, as opposed to the Robot protocol.

There are also the Martin and Wraase modes. These are used primarily by DX stations and are not as popular as Scottie.

Finally, there are the AVT modes. Two are provided: the 94-second and the 188-second. Each of these modes has a QRM and narrow bandwidth toggle (as does the actual AVT system). Pictures sent and received in the AVT modes are, in my opinion, the best of all protocols! Noise and QRM affect the received picture much less noticeably than in the other modes.

While difficult to objectively quantify, I ran some experiments on a UHF path of about 35 miles. I used frequency modulation, and carefully controlled signal levels to yield approximately 50% quieting. The S-meter was constantly observed to assure compliance to a controlled standard. Ken Starck WB3AXC, using a Robot 1200C, digitized a picture of himself and sent it in Robot 72-second color, Scottie SC1, and AVT 94-second. Each picture was saved in one of the four internal Robot memories. Photo C shows the results of this experiment. The difference between these modes on HF using SSB are even more dramatic. Documenting and recording these differences is difficult, however, as conditions on HF change drastically from one moment to the next.

The Results

Perhaps the best thing about the Martin Emmerson EPROM is that it makes the Robot 100% compatible with virtually any SSTV standard in existence. The picture quality in any of these modes can be very good indeed. Photo D shows a picture received on 14.230 MHz from Jim K4TGC in Pulaski, Tennessee, using 36-second Robot protocol. Conditions were good and there was very little interference. Photo E is a relayed picture of

my family that I transmitted to another station on 2 meters. The other station, located about 35 miles away, stored my picture in the Robot's internal memory and sent it back.

The Robot 1200C with the Martin Emmerson EPROM really shines when used under the control of an IBM compatible computer and proper Robot control software. The Robot 1200C has a rear-mounted parallel port, using a DB-25 connector, that may be interfaced with a PC clone.

To take advantage of this feature, a special parallel interface board must be installed in your computer (Photo B). I purchased mine from Martin Emmerson, but as of this writing others may be available that will work equally well. *[Ed. Note: Another appropriate parallel interface board is the PIO-12 made by Keithley Metrabyte Corporation, 440 Myles Standish Blvd., Taunton MA 02780. Phone: (508) 880-3000.]*. Inquiring on 14.230 MHz will also yield information on other possible manufacturers. A cable connects the interface board in the computer to the Robot rear parallel connector.

There are several excellent Robot control programs on the market that are a subject in themselves. Basically, these programs allow the operator to enhance the operation of the Robot 1200C. Pictures saved in Robot memory may be manipulated, changed in size, and cut and pasted with other pictures. Pictures may also be saved as disk files for permanent storage and recall. Hits in the picture as a result of noise or fades may be eliminated or minimized.

Special test patterns and graphics may be called up and displayed and transmitted. The picture shown in Photo C was composed with a PC and a Robot control program called "Hi-Res, Version 1.4" by Tom Jenkins N9AMR. The Robot may also be commanded into transmit or receive, SSTV modes changed, and video inputs/outputs selected. Other popular control programs are SCAN (written by Bert Beyt W5ZR), SSTV (originally written by Jim Williams KC5VC, modified by G4UKL and now offered by Garnet "Beb" Bebermeyer WB0UNB) and IMAGE (offered by Dick Isely WD9GIG). These control programs offer different features and really expand the capabilities of the Robot 1200C.

In summary, the Robot 1200C is the only true stand-alone SSTV system available. With it, a video camera, and a transceiver, you have a complete SSTV system. All that is required is a connection to the receiver's audio, transmitter audio in, and video in from any video camera. A conventional color TV or video monitor will display the captured pictures.

The Robot 1200C is capable of capturing full color video frames from any NTSC color camera, such as a camcorder. It will also function well with monochrome cameras. It is possible, using red, blue, and green filters, to store and send full color pictures using only a monochrome camera. With the modifications described, it will hold up to four high resolution color images in its internal memory. These may be images received off the air, or images captured from your camera. It will store up to 12 low resolution images, such as eight-second black-and-white pictures. All SSTV modes may be selected from the front panel without a computer. The addition of the Martin Emmerson EPROM Version 4.0 has updated the Robot 1200C to a state-of-the-art SSTV system, second to none.

I would be happy to answer any questions in reference to the EPROM Version 4.0 or the Robot 1200C. I hope to hear some new voices on 14.230 or 14.233 MHz. SSTV takes place daily on these frequencies. Drop on by and give a call, someone will be there to help you. ■

Contact Dick Goodman WA3USG at 199 Maple Lane, Mechanicsburg PA 17055. Please send an SASE for any information you request.

TRIDON 2000 AM 450 MHz TRANSCEIVER $324.95

TRIDON FM TRANSMITTERS 900 MHz 1200 MHz $359.95

1 450 TRANSMITTER
Power output is 3W peak; two independent audio systems (Sub-carrier and On-carrier). 10 pin camera connector on back-BNC or RCA connectors on front; SYNC stretcher for optimum composite video; standard crystal frequency: 439.25 MHz or 434.00 MHz; powers video camera (10 pin connector), requires 13.8V DC at 600 MA plus camera power (1 amp); RF tight aluminum cabinet with brushed aluminum panel; size: 2.2" x 5.25" x 5.5".

2 450 TRANSCEIVER
Power output is 3W peak; 10 pin camera connector on back panel, BNC or RCA connector on front panel; monitor video from camera or detected video output; all new video and audio circuitry with SYNC stretcher; new two channel audio system on transmit; new more powerful video transmitter; standard crystal frequency: 439.25 MHz or 434.00 MHz; .8 dB NF GaAsFET pre-amplifier; RF tight aluminum cabinet with brushed aluminum panel; size: 2.2" x 7" x 5.75"; relay switched antenna.

3 FM TRIDONS Both Have:
Pre-emphasis circuitry. "N" connector; RF tight aluminum cabinet with brushed aluminum panel custom designed by W9YL; cabinet size: 2.2" x 6.2" x 5.5"; requires 13.8V DC at 2 amps; large heat sink
900 MHz: 915 MHz FM-ATV transmitter; power output is 8W; 4.5 MHz audio Sub-carrier; uses new phase lock loop crystal controlled exciter.
1200 MHz: 1255 MHz FM-ATV transmitter (any optional frequency); power output is 4-5W. 6 MHz audio Sub-carrier.
440 MHz FM-ATV Tridons available on special order.

Call or write for our complete ATV brochures including 450, 900, 1200 MHz transmitters and receivers, antennas, amplifiers, and line samplers.

Price Class: Kit, $50; Assembled, $70.

The ATV-3 Downconverter

Tune in to ATV with this economical kit.

Photo. The completed ATV-3 downconverter kit mounted in a case.

It's becoming more difficult to find companies willing to cater to the kit builder, but there are a few brave souls out there who have continued to supply project kits to those folks hopelessly addicted to rosin smoke. One of those companies is Communication Concepts, Inc., which has supplied many different types of linear amplifier and ATV-related kits to hobbyists for many years. Their ATV-3 GaAsFET Downconverter is a relatively new kit that has not received much fanfare.

The ATV-3 hooks up between your TV set and a good 70 cm antenna. With the ATV-3 in-line you can tune the entire 70 cm ATV band and convert it down to channel 3 or 4 on your TV. Although the converter tunes from 420–450 MHz, the commonly used ATV frequencies are 439.25, 434, 427.25, 426.25 and 421.25 MHz.

I discovered the ATV-3 after scouring the countryside for a reproducible kit for a group kit building session at our radio club. After putting together the kit from CCI, I was satisfied that it perfectly suited the requirements I had established for our kit building session: The quality of the double-sided printed circuit board and components is superb, and, most importantly, the sensitivity and performance of the finished product was much better than I expected!

Let's break out the magnifying glass and take a closer look at this kit.

Assembly

The total construction time ended up being about two hours. Due to the complexity of mounting several components, a beginner kit builder might want to get some help from someone a little more experienced in mounting the four surface mount capacitors and the two small toroidal inductors. Most of the other 52 components would not really pose a construction problem to a beginner. By following the step-by-step assembly instructions, and referring to the illustration, proper component placement is a breeze.

After helping to assemble 25 other circuit boards, I have cataloged a few possible "problem areas" that may be a concern to the novice kit builder. I talked with Roger Southworth, owner of CCI, and he plans to incorporate some of these suggestions in the next edition of the construction guide. Here, briefly, are my construction tips:

•The #30 gauge wire supplied for the 15-turn toroid inductor is the supplied red wire, and the #24 gauge wire for the 5-turn/3-turn toroid inductor is green.

•Q4, an MPSH-81 transistor, should be mounted as close to the printed circuit board as possible. Mounting this transistor at the prescribed height of ¼" may cause the transistor to "ring." It could also create a self-oscillation, causing a raster-type blank screen image to appear within the passband of a received ATV signal.

•Before soldering them on the circuit board, cut the leads short on the supplied MRF 966 and the MRF 901. This will make it easier to install the other components once the transistors have been soldered in place.

•The varicap diode, MV2205, is actually an MV2105. This will be corrected in the next printing of the instruction guide. In mounting the varicap diode, make sure that the flat part of the TO-92 case goes against the trimmer capacitor, C-23.

•The two "hairpin" type inductors are not drawn to scale. Be sure to follow the directions and make them 0.4" high off the printed circuit board. Their width can be governed by the pre-drilled holes in the printed circuit board.

•Keep all lead lengths as short as possible, including the lead lengths of the exposed center conductor of the 50 ohm transmission line.

•You might want to opt for purchasing a panel-mounted potentiometer. That way you can change ATV frequencies once you have mounted this circuit in a shielded enclosure.

•The "double balanced mixer," a rectangular can with eight pins, can be installed improperly if you're not careful. Once it is soldered in place, it would be almost impossible to remove it if you installed it backwards. There is a blue-colored alignment pin which is mentioned in the instructions. Follow these instructions carefully to ensure proper installation.

Alignment and Testing

If you have assembled the kit properly, a "smoke test" will certify your expert kit building techniques. The alignment process can be as important as making sure that the kit was assembled properly. If the kit falls off on performance, you can be almost certain that the kit has not been properly aligned. If you do not have a service monitor, it is absolutely imperative that you have a friend transmit an alignment signal on 70cm ATV. Do not attempt to align the downconverter with an ATV transmitter located in the next room—overloading the downconverter with a transmitter two feet away will make the alignment process frustrating, if not impossible.

Roger's suggestion of starting off with a commercial UHF signal as a means of rough alignment is helpful. Once you have found a commercial UHF signal and you step through the alignment procedures, ask a friend who has an ATV transmitter to supply an alignment signal (which is an order of magnitude weaker than a commercial station) for your final tweaking. If the transmitted signal is located a few miles away from your downconverter, this will help you in ensuring that the system is properly aligned and the downconverter is not being swamped.

By tuning capacitor C5, any commercial UHF television images can be effectively notched out. This adjustment may not be readily apparent, since C5 has literally no effect on the received 70cm signal. If images appear within the ATV range of the downconverter tuning potentiometer, this is the first setting to check in order to properly notch out these MEGA-ERP power television signals.

How Does It Work?

Out of the approximately 25 different hams who participated in the Dayton Amateur Radio Association kit building session, there wasn't a single dissatisfied customer. On-the-air tests with another commmercially available GaAsFET downconverter showed a slight edge when compared with the ATV-3 (weak signal reception). I couldn't see any detectable difference on stronger local signals. Even though I'm near several large commercial TV stations, the ATV-3 performs well with little interference from these stations.

This kit allows you to enjoy the best of both worlds. . . the chance to burn your fingers on the ol' soldering iron *AND* the satisfaction of constructing an extremely high-quality circuit.

Other Comments

This kit does not come with an enclosure or AC adapter. For the kit builders, I came up with a number of local sources for the hardware and chassis that we ultimately used for this project. For the type and size of enclosure you choose for your downconverter, you are limited only by your imagination. A simple power supply can be fabricated with a handful of junk box parts, or a visit to your local Radio Shack.

With kits still available from folks like Communication Concepts, the revered and esoteric art of electronic kit construction will remain alive and well. . . for those who love the smell of burning rosin flux in the morning!

BARTER 'N' BUY

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The *73 Flea Market*, Barter 'n' Buy, costs you peanuts (almost)—comes to 35¢ a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to the *Barter 'n' Buy*, Donna DiRusso, Forest Road, Hancock NH 03449 *and get set for the phone calls.*

HAMSATS

Amateur Radio Via Satellite

Andy MacAllister WA5ZIB
14714 Knightsway Drive
Houston TX 77083

A Mission of Firsts

The Shuttle Amateur Radio Experiment (SAREX) on the STS-37 *Atlantis* mission was a success, in spite of a broken wire precluding two-way packet and slow-scan television (SSTV) contacts with the crew. SAREX is a joint effort of NASA, the ARRL, AMSAT and the Johnson Space Center Amateur Radio Club.

On April 5 of this year, the first all-ham crew went to orbit with the Gamma-Ray Observatory (GRO), experimental "scooters" to be evaluated for future space-station use, and the most ambitious SAREX experiment to date. Amateur radio has two reasons to be included on shuttle flights. The first is to encourage public participation in the space program, and the second is to support educational opportunities derived from the voice and digital communications from space.

The crew included pilot Ken Cameron KB5AWP, commander Steve Nagel N5RAW, mission specialist Jerry Ross N5SCW, mission specialist Linda Godwin N5RAX, and mission specialist Jay Apt N5QWL. Ken, licensed since 1984 before coming to NASA, brought an enthusiasm to the SAREX program that was quickly shared by the other members of the STS-37 mission. Starting with Jay, the crew members took and passed their Technician-class tests. Linda became the first female ham in space.

Equipment Configuration

The ham gear on the *Atlantis* for STS-37 included an impressive array of equipment, such as a Motorola 2 meter hand-held transceiver, video and audio recorders, headset, color camera and monitor, fast-scan TV (FSTV) module, slow-scan TV (SSTV) scan converter, computer with tracking and packet software, packet module, window-mounted antenna system, and all the necessary cables to connect it together.

Amateur FSTV had never before been tried in space. This was a first, and it worked. The receive converter used by the crew measured only a few inches on a side. It connected to a Panasonic display and recorder unit, and to a small L-shaped antenna that was a part of the 2 meter loop antenna mounted with Velcro in one of the shuttle's flight-deck windows.

Some of the items in the equipment list had not been previously qualified for use on the shuttle. The Panasonic portable TV/VCR was one example. It resembles a lap-top computer with a flip-up video display and a VCR where a computer's keyboard would reside. The case is plastic, and considered inflammable. To qualify for flight, it was coated with a special foil and painted. The liquid-crystal display was tested to ensure that it would not shatter or come apart when hit with weights dropped from specific heights. It passed, and will likely be used on future flights.

The shuttle's ham antenna system acts like an outside-mounted quarter-wave whip, even though it is a shielded loop installed inside the shuttle. As with a whip antenna mounted on a large vehicle, there are signal nulls to contend with. If an automobile were placed in orbit with a roof-mounted antenna, reception from stations "under" the car would be poor. This occurs often with the shuttle whose orientation, with respect to stations on the earth, is constantly changing.

The packet system used on STS-37 was the same as that on the STS-35 flight. Several stations heard the beacon transmissions on 145.51 MHz from the *Atlantis*, but due to the broken wire in the cable between the scan converter and the radio, no audio from the radio got to the other equipment. Lou McFaddin W5DID inspected the cable after the mission, found the problem, and began repairs. The connection behind the plug to the scan converter apparently was flexed one too many times. The assembly will be potted and stiffened before it is used again, even though it had worked without problems on the previous flight and during many tests.

Photo A. STS-37 Atlantis *heads for space with an all-ham crew.*

Photo B. Gil Carman WA5NOM and students from the Clear Lake Independent School District communicate with the astronauts of STS-37.

The SSTV system also suffered from the broken wire, but even though pictures could not be uplinked to the shuttle via slow-scan, they could be sent to the ground. Many hams monitored the pictures sent from the shuttle via the heavily-modified ROBOT scan converter and 2 meter transceiver. On the third day of the mission, Ken KB5AWP configured the system to send "frame-grabbed" pictures of the extra-vehicular activity (EVA) of Jay N5QWL and Jerry N5SCW working on the GRO high-gain antenna.

Space-Bound "Real" TV

Earth-to-space frequencies on 70 cm are limited to only 3 MHz. For the flight of STS-37, several stations were given permission by the FCC to send normal (at least 6 MHz wide) TV to the shuttle. Jim Steffen KC6A was the first to have his transmission received on the shuttle. While SSTV had been used for uplink experiments years ago on a shuttle mission with Tony England WØORE, this was the first time for wideband fast-scan TV. With 14 kW effective radiated power, Jim's pictures came through very well throughout most of the pass.

Andy Bachler N9AB sent a video of the shuttle's launch up to space allowing the crew to see their own liftoff via the Amateur FSTV link while still in orbit. This was another first. Others, including the Marshall Amateur Radio Club (WA4NZD) and the Goddard Space Flight Center Amateur Radio Club (WA3NAN transmitting via a 40 foot dish at the US Naval Academy at Annapolis, Maryland, manned by Bob WB4APR), successfully sent video to the shuttle. For terrestrial ATV activity, large antennas are used on both ends of long-distance contacts. With only the equivalent of a small whip antenna on the shuttle, the sending station on the ground needed to overcome the limitations of the shuttle's antenna as well as the distance penalty. Antennas planned for the space station later this decade should be better.

HOMING IN

Radio Direction Finding

Joe Moell PE KØOV
P.O. Box 2508
Fullerton CA 92633

Three-Second T-Hunts

Remember those spy movies and TV shows where the good guys hide a transmitter on the bad guys' car and tail them to their hideaway? The best tracking gizmos featured a little screen with a moving map on it. The car with the crooks (or enemy agents, or whatever) would appear as a blinking dot on the hero's map screen.

I'm sure that back then these stories helped fuel the paranoia of people who were positive that their every move was being monitored by trench-coat-wearing agents in panel trucks. But we T-hunters knew it couldn't be done that easily. Ordinary Radio Direction Finding (RDF) sets "display only incoming signal azimuth," plus a rough idea of distance. No single tracking device can pinpoint a vehicle down to within a few feet. Multiple-station triangulation normally is not precise enough either, because small angular bearing variations from any station cause significant triangulation error.

Well, it's not science fiction anymore. Welcome to the nineties, and what promises to be the decade of super-accurate Automatic Vehicle Monitoring (AVM). International Teletrac Systems is the first to bring AVM to market, starting in Los Angeles. The network is in place, dealers are ready, and ads are appearing on TV.

A minor media war is going on between Teletrac and LoJack (see "Homing In," May 1991) for the stolen vehicle recovery market. Their technologies have major differences. VHF/UHF AVM systems like Teletrac use no directional arrays, loops, or beams. There are no Doppler homing units. Instead, AVM uses a wide-aperture, time-difference-of-arrival (TDOA) system.

Previous "Homing In" columns (September and November 1989) have described TDOA transmitter hunting techniques for hams, but they have all used narrow aperture (less than one-half wavelength) antenna spacing. AVM antenna spacings are measured in miles instead of inches.

Teletrac Versus Thieves

For a fixed price plus a monthly service fee, a Teletrac contractor will install a chalkboard-eraser-sized AVM transponder in an inconspicuous spot in your car. These transponders, called Vehicle Locator Units (VLUs), are manufactured under license by several Japanese firms.

The VLU contains logic to detect startup by an unauthorized person. It taps into the key warning buzzer circuit and other available signals. If a thief starts the car without a key, or trips any other alarm devices on the car, the VLU transmits its "I'm being stolen" digital message and an ID number to Teletrac's control center computer. The computer immediately issues a "location request" to start the RDF process.

Receiving a location request transmission makes the VLU switch from the "alert" channel to one of the many "location" channels and send out a transmission burst. All receiver sites listen for the burst and pass along what they hear (time of signal, the strength, and ID) to the control computer. The computer selects the four strongest site signals and looks at the differences in their time of arrival. Using an advanced RDF technique called multilateration, it locates the source of the signal.

About three seconds after the request transmission, the number crunching is completed and the computer displays the location of the vehicle as a mark on a computer-generated map (see Photo A). Accuracy is typically within 100 feet. As the thief drives away, the system issues more location requests and calculates the speed and direction.

After notifying the owner and/or authorities as appropriate, Teletrac operators continue to follow the stolen car. They update law enforcement agencies by phone, or send computer data to police/sheriff computer screens. All the while, the computer is recording the path on disk for possible court use as evidence. If another crime is committed en route, this record becomes even more important.

Note that none of the receiver sites have directional antennas or any other way to independently determine the direction of incoming signals. Direction of arrival at each site is unimportant; only the relative times of arrival are required to locate the transmission.

Even with antennas spaced many miles apart, time of arrival differences are measured in nanoseconds (billionths of a second). This means that the transmissions must be very short to ensure RDF accuracy. It takes precise timing and a fast computer. The first of the four receivers is used as a time reference and the other three sites give relative time information.

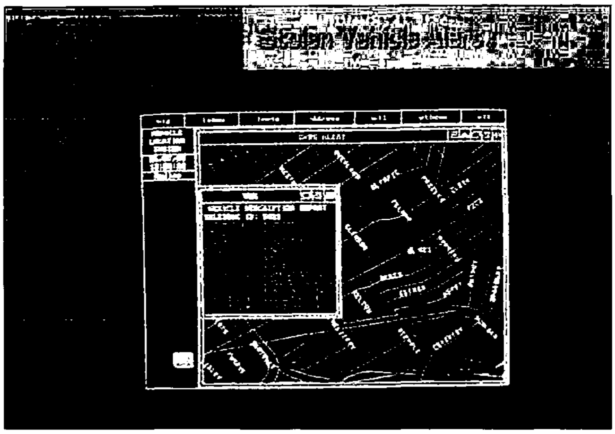

Photo A. Teletrac claims 100-foot accuracy with its vehicle location system.

Teletrac to Hams: Stay Off 70% of 33 Centimeters

The advent of AVM directly affects amateur radio, because it is taking place in our 902 to 928 MHz ham band. From the time hams first received a 33cm allocation, it has always been on a shared basis. The FCC established the priorities as follows:

1. Military radiolocation
2. Industrial/Scientific/Medical (ISM)
3. Government
4. Automatic Vehicle Monitoring
5. Amateur Radio
6. Low-power (Part 15) devices

Hams must not cause interference to the military, government, and AVM.

They must accept any QRM received from military, ISM, government, and AVM on this band. (ISM is a transmit-only service.)

Two years ago, Southern California hams were beginning to discover the usefulness of 902 to 928 MHz. A few repeaters and links were being tested, an ATV network was already working, and advanced experimenters were trying wideband high-speed digital message forwarding. Then Pacific Telesis announced the start of AVM testing. At a meeting between Pac-Tel and the Southern California Repeater and Remote Base Association technical committee (SCRRBA) in January 1990. Pac-Tel made it clear that interference from hams would adversely affect its Teletrac network.

As a result, the SCRRBA suspended all coordination on the 33cm AVM segments, and wrote a new band plan. In the new plan, weak signal work and repeater inputs are placed from 902 to 903 MHz. Amateur links and repeater transmitters on mountaintops and at other communications sites are being coordinated from 927 to 928 MHz, adjacent to the high power paging transmitters that are proliferating above 928 MHz. Putting weak signal ham operations at the low end of the band minimizes QRM from the paging systems.

No ham activities are being coordinated in the 903 to 912 and 918 to 927 MHz ranges, keeping them clear for AVM. Amateur television users have been coordinated on one simplex channel, with a video carrier at 913.25 MHz. *[Ed. Note: In Los Angeles, 919.25 MHz is now being used for an ATV repeater output. Two are currently operational.]*

Vestigial sideband is recommended to keep lower sideband energy from affecting AVM receivers near 912 MHz. If the FCC authorizes AVM systems between 912 and 918 MHz, this band plan may have to be changed.

According to the SCRRBA Data Base Manager Karl Pagel N6BVU, other coordinating committees around the country are inquiring about the new Southern California band plan, as Teletrac and other companies expand operations nationwide. As the AVM system expands into other major U.S. cities, don't be surprised if this plan is used for your area.

Climb Every Mountain

To cover its 4,500 square mile service area in four Southern California counties, Pac-Tel Teletrac has installed 41 receiving sites. They are not at those familiar cellular phone towers along the freeways. Instead, they are on the area's high hills and mountains, to give maximum coverage. More sites are being added to fill coverage "holes" due to shadowing in foothill areas.

The computer program is designed to calculate the location of 70 vehicles each second. Of course there aren't that many AVM-equipped stolen cars out there at one time (even in Los Angeles). The additional capacity is sold to large companies and public service agencies so they can keep constant track of all their vehicles.

Owners of large truck fleets are looking to AVM to save money by more efficient routing and elimination of empty-load runs. Putting AVM into law enforcement vehicles would allow dispatchers to instantly know which squad car is closest to the scene of an emergency.

But AVM has potential far beyond fleet management and recovery of stolen vehicles. The technology behind Teletrac was originally inspired by a well-publicized kidnapping in Florida. Teletrac marketeers say that its inventors originally set out to develop a personal tracking system to prevent similar tragedies.

Miniaturized transponders for that purpose are not here yet, but they are probably not far off.

Also in the works is a "panic button," so Teletrac owners can call for help from their cars. Designers are even considering a remote disable feature, to permit authorities to flash the lights, honk the horn, or even stop the engine when you report your car stolen.

AVM system designers have their technical problems, of course. They may be able to keep hams off their frequencies (see sidebar), but they must accept interference from other users. Military radiolocation transmitters have caused big-time QRM at high AVM receiver sites.

Industrial emitters can cause headaches, too. For instance, those anti-theft devices at the doorways of record stores can jam an AVM site under some circumstances. New state-of-the-art receivers are solving these problems.

Big Brother?

It's eleven o'clock—do you know where your car is? Teletrac owners can find out in seconds by dialing up a special phone number and giving their ID and password. I can hear it now: "Dad, can I have the keys tonight? Not for your sports car, I want the old wreck without the Teletrac!"

But don't get the idea you can use Teletrac to "bug" someone else's car. The installer is supposed to see proof of registration before installing a VLU.

The AVM market is taking off. Teletrac is going into Chicago, Detroit and Dallas/Ft. Worth this year. Miami, New York and New Jersey are scheduled for next year. Hams with a technical background in RF are finding jobs in installation and maintenance of the dozens of sites required for each system.

Teletrac has over two dozen software engineers on staff—it's a BIG computer program. Furthermore, numerous other companies are eyeing the AVM scene and making FCC applications. Perhaps there is a place for you in the AVM field.

SPECIAL EVENTS

Ham Doings Around the World

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the January issue, we should receive it by October 31. Provide a clear, concise summary of the essential details about your Special Event. Check /HAMFESTS on our BBS (603-525-4438) for listings that were too late to get into publication.

JUL 4

HARRISBURG, PA The Harrisburg RAC will sponsor a Flea Market at the Bressler Picnic Grounds, Exit #1 of I 283, PA 441 North, and follow signs. Admission $3. Tailgating $3. Tables in pavillion $10 in advance, $12 at the gate. Set-up at 6 AM for vendors and tailgating. No overnight camping. Talk-in: 147.30/.90 and 52/52. Contact ***Dave Dormer KC3MG, (717) 939-4957.***

JUL 5

CAMILLUS, NY VE Exams will be held at the Town of Camillus Municipal Bldg. beginning at 7 PM. Test fee for Technician through Extra class is $5.25. Talk-in on 147.300. Contact ***John Patchett KB2ERJ, (315) 487-0298.*** Please bring two forms of ID and a copy of your license.

JUL 6

SALISBURY, NC A Firecracker Hamfest, sponsored by the North Carolina Chapter of Triple States RAC, will be held at the Civic Center from 8 AM-4 PM. Advance tickets $3, $4 at the door. Tables $5. W5YE VE Exams at 1:30 PM; pre-register by sending 610, copy of license and $5.25 fee to ***Isabell Ledford, PO Box 826, Collamee NC 27014.*** For advance tickets contact ***Walter Bastow N4KVF, 3045 Highrock Rd., Gold Hill NC 28071.***

OAK CREEK, WI The South Milwaukee ARC will hold its 21st annual "SWAPFEST" at the American Legion Post #434 in Oak Creek WI from 7 AM-2 PM. Free overnight camping. Admission $4. Talk-in: 146.580 MHz FM simplex and most local repeater frequencies. For more details and a map, write to ***The South Milwaukee ARC, PO Box 102, South Milwaukee WI 53172-0102.***

JUL 6-7

WESTON, WV The West Virginia State ARRL Convention, sponsored by the West Virginia State AR Council, will be held at the Jackson's Mill State 4-H Camp near Weston, WV beginning at 8 AM both days. Set-up Fri. from 5:30 PM-11 PM. Admission $5. Flea market tables free (admission ticket required). ARRL VE Exams at 8 AM Sat. Contact ***Bob Robinson KU8C, (304) 366-0132*** by June 30 to pre-register.. Talk-in: 144.79/145.39. For advance tickets write ***Sue Goodwin N8JNL, 103 Cleveland Ave., Nitro WV 25143.*** For info call ***Chuck McClain K8UQY, (304) 366-5401.***

JUL 7

PITTSBURGH, PA The North Hills ARC of Pittsburgh PA will hold its sixth annual Hamfest from 8 AM-3 PM at the Northland Public Library, 300 Cumberland Rd., between US Rt. 19 North and McKnight Rd., north of Pittsburgh. Free admission. Free tailgating-one space/vendor. Wheelchair accessible. Limited indoor tables $10 each. Contact ***N3DOK, (412) 367-2393*** for table info.

JUL 9-19

IRELAND Final arrangements have been completed for the first expedition to Fastnet Rock Lighthouse off the South coast of Ireland. Callsign EJ7FRL has been assigned. For info contact ***EI3GU, 31 Seaview Park, Shankill, Co. Dublin, Ireland.***

JUL 12-13

MAPLEWOOD, MI Amateur Fair '91 will be held at the Aldrich Arena. This event is oriented to amateur radio operators, electronics hobbyists and personal computer users. Outside flea market and commercial exhibits start at 6 PM Fri. On Sat. the flea market will be from 6 AM-3:30 PM; Commercial exhibits 8 AM-3:30 PM. Admission is $5 at the door. Children under 6 admitted free when accompanied by an adult. Ticket holders may sell from the giant outdoor flea market at no additional cost. For commercial booth and club exhibit info contact ***Amateur Fair, PO Box 26331, St. Paul MN 55126***, or call ***(612) 653-9999.*** Computer users can call ***HAM-LINK*** at ***(612) 426-0000*** (300-2400 baud).

JUL 12-14

NORTH DAKOTA/MANITOBA BORDER North Dakota and Manitoba's 28th annual Hamfest will be held at the Peace Garden on the USA-Canadian border. Registration begins on the afternoon of the 12th. The Hamfest will end about noon on the 14th. Breakfast for all will be on Sun. morning. Special Event Station VE4IHF/Ø will operate Fri. and Sat. Ample camping spots on-site. The Peace Garden is located just a few miles north of Dunseth ND, or a few miles south of Boissevain, Manitoba.

JUL 13

PETOSKEY, MI The Straits Area ARC will sponsor a Swap Shop at the Emmet County Fairgrounds 4-H Building from 8 AM-1 PM. Tables $3-Door $2.50. RV parking on grounds. Talk-in: .08-.68 or .52. For general info/reservations contact ***Clark Rouse KA8TIL, (616) 582-6455.*** VE Exams contact ***Tom Romanauski N8KHE, (616) 436-5033.***

JUL 13-14

WOODLANK PARK, CO The Mountain ARC will hold a Flea Market Swap 'N Shop at the Red Rocks Campground, Pike National Forest. Camping in the pines; entry for camping or set-up permitted late afternoon of July 12th. Advance reservations required for overnight camping. For camping reservations write to ***MARC, Box 1012, Woodland Park CO 80866***, or call ***Joe Tafoya NØCMD, (719) 687-3641*** or ***Bob Whipple N/0FCR, (719) 687-9025.*** Free admission. Camping $7.50 per night. Tailgate space $7.50 per space (no double fee if camping and selling).

INDIANAPOLIS, IN Indianapolis Hamfest/Computer Show (Indiana's largest electronic, amateur radio and computer related market and flea market) will be sponsored by the Indianapolis Hamfest Assn. This will be held at the Marion County Fair Grounds at the intersection of I-465 and I-74 on the southeast side of Indianapolis. The show is open from 7 AM-4:30 PM both days. Tickets $8 at the gate, $6 in advance. For info call ***(317) 326-2146.*** Mailing address: ***Indianapolis Amateur Radio Assn., PO Box 11776, Indianapolis IN 46201.***

JUL 14

DOWNERS GROVE, IL The DuPage ARC will hold their 9th annual Hamfest/Electronics/Computer Show at the American Legion Post 80. Free parking. VE Exams $5.25 for all classes except Novice, which is free. Walk-ins welcome. Tickets $3 in advance, $4 at the gate. Set-up at 6 AM. Gates open to the public at 8 AM. Talk-in: 145.250/.600, 224.68/1.6, 442.55+5 PL114.8. For reservations, send SASE to ***Hamfest Chairman W9DUP, PO Box 71, Clarendon Hills IL 60514.*** For info call ***Ed Weinstein WD9AYR, (708) 985-9256.***

BOWLING GREEN, OH The Wood County ARC will sponsor its 1991 Ham-A-Rama at the Wood County Fairgrounds on Poe Rd. from 8 AM. Tickets $4 in advance, $5 at the door. Tables $10. Talk-in: 147.78/.18 K8TIH. For tables, info, contact ***Bob Fyfe KA8YWQ, (419) 352-3260.***

AUGUST, NJ The Sussex County ARC will hold a Hamfest, beginning at 8 AM, at the Sussex County Fairgrounds, Plains Rd., off Rte. 206. Free parking. Admission $4 (XYL's and harmonics free). Tailgate $6, indoor spaces $8 per space. Limited supply of tables. Talk-in: 147.90/.30, 222.90/224.50, 146.52. Contact ***Don Stickle K2OX, 185 Weldon Rd., Lake Hopatcong NJ 07849. (201) 663-0677.***

JUL 18-20

CHARLOTTE, NC Personal Computer Interfacing-Practical Instrument Automation, Networking and Control Techniques, including microcontrollers. A 3-day hands-on workshop. Contact ***Dr. Roy Jones, (703) 231-5242 or (703) 231-6478.***

JUL 20

SOUTH BURLINGTON, VT The Northern Vermont Mid-Summer Hamfest Committe will sponsor a Hamfest at the South Burlington Middle School from 8 AM-3 PM. Admission $3 (US). VE Exams at 2 PM. Tables available. Talk-in: 145.47/-600 or 146.85/±600. Contact ***Joe Tymecki N1DMP, (802) 893-6458*** or ***Tom Taylor N1EXY (802) 893-4834.***

UNION, ME The 4th annual Union Hamfest/Computer Fair, sponsored by the Maine Hamfest Assn. Inc. will be held at Union Fairgrounds on Rte. 17 from 8 AM-2 PM. Admission $2 for sellers; $3 for non-sellers. Tailgate set-up begins at 7 AM. Free parking. FCC VE Exams. Camping/RV spaces available for Fri. the 19th and Sat. the 20th. Contact ***Rod Scribner KA1RFD, 19 South Grove St., Augusta ME 04330. (207) 622-9197.***

GARDEN GROVE, CA The Catalina ARA will sponsor Hamfest '91 at Cypress College from 8:30 AM-5 PM. Contact ***CARA, PO Box 425, Garden Grove CA 92642-0425.*** (Vendors, please request vendor information).

JUL 21

WASHINGTON, MO The Zero Beaters ARC will hold its 29th annual Hamfest at the Bernie H. Hillerman Park (Washington Fairgrounds) from 6 AM-3 PM. Admission is free. Flea Market parking is $2 a space. Walk-in VE Exams begin at 10 AM. Bring original license and a photocopy. Talk-in: 147.240 repeater. Contact ***Ed Southall WDØELL, Rt. 1 Box 105, New Haven MO 63068. (314) 459-8581.***

CAMBRIDGE, MA The MIT Electronics Research Society, the MIT Radio Society and the Harvard Wireless Club will hold a Tailgate Electronics/Computer/Amateur Radio Flea Market from 9 AM-2 PM at Albany and Main Streets in Cambridge. Admission $1.50. Free off-street parking. Sellers $8 per space at the gate, $5 in advance (includes 1 admission). Set-up at 7 AM. For space reservations or info call ***(617) 253-3776.*** Mail advance reservations before the 5th to ***W1GSL, PO Box 82 MIT BR., Cambridge MA 02139.*** Talk-in: 146.52 and 449.725/444.725-pl 2A-W1XM/R.

JUL 25-28

CEDAR RAPIDS, IA The 25th Central States VHF Society Conference will be held at the Sheraton Inn. This event is for all VHF/UHF/SHF operators. Pre-registration forms are available from ***Al Groff KØVM, 1446 Council St. NE, Cedar Rapids IA 52402. Home phone (319) 393-8134.*** Make hotel reservations by calling the ***Sheraton Inn at (800) 325-3525*** or ***(319) 366-8671.*** To obtain the special room rate, be sure to indicate that the reservation is being made for the CSVHFS Conference.

JUL 26-28

FLAGSTAFF, AZ The Amateur Radio Council of Arizona will sponsor the Fort Tuthill Hamfest at the Ft. Tuthill County Fairgrounds. Camping facilities for self-contained campers. No power supplied. $5 per night inside fenced area. Tailgate fee is $10. Tickets $2 each or 3/$5. VE Exams on Sat. Talk-in: 147.68/.88, 447.125/442.125. For info contact ***Chairman, Lee Pemberton WB7BXB, 759-8737*** or ***Vice Chairman, Cliff Hauser KD6XH, 744-9095.***

LANCASTER, PA The Red Rose Repeater Assn., Inc. will sponsor a Computer Fest at the McCaskey High School from 9 AM-3 PM. Set-up at 7 AM. Admission $4 with children under 14 free if accompanied by a paying adult. Talk-in 147.015/.615. Mail ***Red Rose Repeater Assn., Inc., PO Box 8316, Lancaster PA 17604.***

JUL 27

NORTH BEND, OR The Coos County Radio Club will sponsor a Radio/Computer/Electronics Swap Fest at the North Bend Jr. High School from 0900Z-1700Z. Free RV/SC parking all week end. VE Exams. Advance tickets $4, $5 at the door. Tables (8' x 30") $15. Commercial Space @ $30.00. Only one free admission per seller, regardless of number of tables. Set-up July 26th, 3PM-6 PM; July 27th, 6 AM-9 AM. Make checks payable to ***Coos County Radio Club, PO Box 349, Coos Bay OR 97420.***

JUL 27-28

OKLAHOMA CITY, OK The 18th Annual Ham Holiday 1991 and ARRL Convention, sponsored by Central Oklahoma Radio Amateurs, will be held at the Hobbies, Arts & Crafts Bldg, Oklahoma State Fair Park. Doors open at 8 AM both days. VE Exams both days. Saturday evening banquet (Tickets $8.50); Flea market, new and used equipment, forums. Admission $6 in advance or $8 at the door. Tables $5 in advance, $7 at the door. Talk-in on 147.03/.63 and 444.20/449.20, PL is 141.3. Send registration to ***CORA Ham Holiday 1991, PO Box 95942, Oklahoma City OK 73143-5942.***

JUL 28

TIMONIUM, MD The BRATS Maryland Hamfest/Computer Fest will be held at the Maryland State Fairgrounds. Set-up at 2PM Sat. and 6 AM Sun. There is no set opening hour. 8' tables (no power) are $25 each. Write or call for special discount rates for 10 or more tables. Tailgating is $5 per space, on sale on the day of the hamfest. Free VE Exams will be held in the Administration bldg. at 10 AM only. Pre-registration required. For exam info and reservations write to ***BARC, PO Box 120, Reisterstown MD 21136.*** For table reservations and hamfest info write to ***BRATS Hamfest, PO Box 5915, Baltimore MD 21208***, or call ***Franz N3HFS, (301) 583-9147***, 24 hours a day.

SPECIAL EVENT STATIONS

JULY

VERMONT Vermont Special Event Stations will operate 25 kHz up from the bottom of the Novice and General band throughout the year, to help Vermont celebrate its 200th Birthday. RTTY/AMTOR/etc. will be in the digital sub-bands. To obtain a Special Certificate, send $1 and SASE to ***Amateur Radio Bicentennial Project, PO Box 200, Graniteville VT 05654.*** Foreign stations, send only SAE and IRC's to cover postage.

JUL 4-6

LOUISVILLE, KY Louisville's Freedom Hall will be the site from which Special Event Station W4CN will operate to celebrate the International Barbershop Singing Convention. Time: 1200-0300 UTC. Frequencies: 20-, 15- and 10 meter SSB, as well as 2 meter FM. Sideband frequencies will be 14.225/.245 MHz, 21.30/.32 MHz and 28.30/.32 MHz. FM operation will be on the Louisville 147.18 MHz repeater and 147.58 MHz simplex. Talk-in will begin on Monday, July 1st, on the repeater frequency. All amateurs contacting W4CN will receive a special commemorative QSL card, courtesy of Yaesu USA. The station is sponsored by members of the amateur Radio Transmitting Society of Louisville. Contact ***Gil Hibben N4LRF, Amateur Radio Transmitting Society, PO Box 7391, Louisville KY 40257-0391. (502) 222-1397*** (daytime).

JUL 6

DELTAVILLE, VA The Middlesex AR Group will operate KB4NGO, 1230-2030 UTC to commemorate Deltaville Heritage Days. Operation will be in the General portion of the 80, 40 and 20 meter bands. For certificate send QSL and SASE to ***Fay Smith KB4NGO, M.A.R.G., PO Box 88, Hardyville VA 23070.***

JUL 6-7

DELTA COUNTY, MI The Delta County ARS will celebrate its 20th Anniversary as an affiliate of the ARRL by operating Station K8ZAS from 1400-0100Z Sat. & Sun. Bands: 10, 15, 20, 40, 80 meter. Frequencies: 28.357, 21.357, 14.280, 7.280, 3.980; CW: Novice CW frequencies. Contact ***Denise, PO Box 923, Escanaba MI 49829.***

LAPORTE, MN The Cass-Hubbard County ARC will operate NØGFK 1500Z 6 July-0300Z 7 July, to honor WØLSC, W.C. Soderlund, formerly of Laporte High School, for writing the curriculum and teaching the First High School Radio Theory Class in Minnesota. The station will operate SSB in the General portion of the 75, 40, 20, 15 and 10 meter bands. Mr. Soderlund will participate as one of the operators while being the Reunion Guest of Honor at the 75th Anniversary of the High School. For certificate, send QSL and SASE to ***W6AAQ, Box 595, Esparto CA 95627-0595.***

JUL 10-11

VERMONT A Special Event Station will operate for the State Capitol Building. The hours are 10 AM-3 PM. The State of Vermont is also providing a special gift to be included with the certificate for those contacts made on the 10th and 11th. Contact ***Amateur Radio Bicentennial Project, PO Box 200, Graniteville VT 05654*** for more info.

JUL 11

PUAKO, HI The Big Island of Hawaii will experience a partial and total solar eclipse from 1630-1837Z. Members of the Big Island ARC will operate Station NH6ES from 0001-2400Z, at Puako HI (within the path of the eclipse). Operation will be in the Novice part of the 10 meter band and in the General segments of the other HF bands. Special QSL cards to those contacting NH6ES. QSL to: ***BIARC, PO Box 1938, Hilo HI 96721-1938.***

JUL 12-13

NORTH DAKOTA/MANITOBA BORDER Station VE4IHF will be operated from the International Peace Garden from 9 AM-6 PM CST. This year the Station will be on with digital modes as much as possible, as well as phone. For a Peace Garden certificate, send 2 IRC and SASE or 1 IRC, SASE and QSL card, to ***Dave Snydal VE4XN, 25 Queens Crescent, Brandon, Manitoba, Canada R7B 1G1.***

JUL 13

WESTON, WV In conjunction with the X-Mas in July celebration at Weston Hospital, the Central ARA of West Virginia will operate Station N8FIP on 10, 15, 20, 40, 80 meters SSB and 20 meter packet, from 1600-0400 UTC. Weston Hospital is

NEW PRODUCTS

Compiled by Hope Currier

QRZ INDUSTRIES

QRZ Industries announces the VB-8A natural voice recorder as a fully assembled kit in a desktop enclosure with RFI/EMI protection. The VB-8A can digitize and store up to 16 dynamically-allocated messages or phrases in stand-alone mode, or 100 messages in a computer controlled "template" mode. A message can be as long as the total message allocation of 100 seconds. Completely microprocessor controlled, the VB-8A even has an auto-incrementing serial number capability (spoken in your own voice). Using a 40 kHz digitizing rate and 14 orders of audio filtering, the VB-8A provides crisp, clean audio to both a 600Ω balanced output and an 8Ω monitor output.

The introductory price of the fully assembled desktop enclosure kit, tested and burned-in, is $375, which includes a full memory configuration and an audio/PTT output cable for any standard amateur transceiver. Factory-assembled VB-8A kits have a 30-day money back guarantee and a one-year warranty. Contact *Advanced Voice Products, P.O. Box 1064, Mauldin SC 29662; (803) 676-1111.* Or Circle Reader Service No. 201.

TELEX COMMUNICATIONS

The Hy-Gain group of Telex Communications has introduced the CONTESTER boom-mike headset. It features a noise-cancelling dynamic mike that favors the voice range (100–8000 Hz) for maximum intelligibility. The mike boom rotates so it can be worn on the left or right side of the head and automatically shuts off the mike when placed upright. The headset's receivers have a 50–15,000 Hz frequency response and compatible impedance for amateur transceivers. The 5′ (1.5m) headset cord is unterminated, to accept any connector suitable for the user's transceiver.

The suggested list price is $102. Contact *Telex Communications, Inc., 9600 Aldrich Avenue South, Minneapolis MN 55420; (612) 884-4051, FAX (612) 884-0043.* Or circle Reader Service No. 202.

OE2DYL

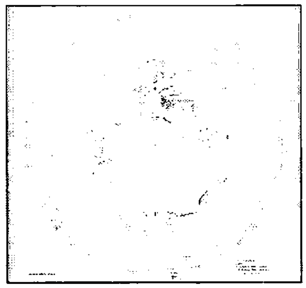
"DX Nets Around the World," List 10, is the new 1991 edition of OE2DYL's popular list containing data about more than 100 active DX nets. The price is US$4 (airmail) for this new list, or US$15 for the package of all 10 editions. OE2DYL is also offering "DX Beam Headings," with short- and long-path bearings and distances to more than 450 locations throughout the world for US$25 (airmail). No checks. To order, contact *Dieter Konrad OE2DYL, Rosengasse 1, A-5020 Salzburg, Austria.* Include an SAE.

EPO SOFTWARE

EPO Software has released a family of copyrighted logging software specifically designed for amateur radio operators. These databases have been developed, refined and improved with the input of thousands of hams worldwide. Each program can generate high-speed hard copy, video or ASCII log files, is suitable for single band or multiband use, and is user friendly and flexible. ELECTROLOG II, "The Electronic Logbook," is a sophisticated, general purpose logging and QSLing program, priced at $19.95. CONTEST LOG & DUPE SHEET ($14.95) is an easy-to-use contest log program featuring RAM-based duping, error-free default entry, and super-quick searching. DXCC AUTOLOG and WAS AUTOLOG ($14.95 each) are specialty logging programs designed for DXers and award hunters. TEN-X LOG ($14.95) is a unique data base that will sort and alphabetize by a variety of fields, including callsign or membership number.

There is a $2 shipping charge for each order. For more information, contact *EPO Software, 7805 N.E. 147th Ave., Vancouver WA 98682; (206) 892-1679.* Or circle Reader Service No. 205.

VECTOR CONTROL SYSTEMS



A Great Circle Map that shows true compass headings and distance for beam positioning is now available from Vector Control Systems. This 22″ x 24″ plastic laminated map, suitable for framing, is plotted in four colors and countries are identified by prefix. It is priced at $35 postpaid. Contact *Vector Control Systems, 1655 No. Mountain, Suite 104-45, Upland CA 91786; (714) 985-6250, FAX (714) 985-3482.* Or circle Reader Service No. 203.

MUSCLE PRODUCTS

Muscle Products has announced a new, unique demoisturant and corrosion preventative, MO-10 MOIST-OUT. This product removes water from circuits and circuit boards, preventing corrosion, and is also a light lubricant and penetrant that will reject and repel dust because of a petrochemical bonding technique that repels airborne contaminants by causing a dipole-dipole interaction, or "cation exchange," on the surface of the metal. MO-10 also removes corrosion and corrosion bridges from PC boards after a light spray and brush application, and prohibits further corrosion from taking place. Its dielectric strength is rated at 45 kV.

MO-10 is available in 16 oz. plastic pump spray bottles, 5 gallon pails, and 55 gallon drums. The suggested retail price for the 16 oz. bottle is $6.39, plus S & H. (Say that you saw it in *73* and get a 10% discount.) For more information, contact *Muscle Products, 188 Freeport Road, Butler PA 16001; (800) 227-7049, (412) 283-0567.* Or circle Reader Service No. 204.

WHATS-UP

WHATS-UP 1.00 is a software tool providing radio amateurs, or educators, with the capability to perform experiments in spacecraft orbital dynamics, as well as monitoring the environment on board several of the OSCARs during individual passes or over long periods of time. Capturing, decoding and displaying telemetry from orbiting spacecraft in real time, in the classroom, is an excellent way of introducing space science to students. WHATS-UP lets you do this using readily available low cost equipment. The documentation covers telemetry, the spacecraft themselves, receiving antennas, radio receivers, modems, and the software used to both decode and display the data in real time and to do a post-pass analysis.

WHATS-UP is available for $35 for a single copy, or $195 for a classroom license of up to 10 users. Contact *Joe Kasser, POB 3419, Silver Spring MD 20918; (301) 593-6136, data BBS (301) 593-9067, CompuServe 70531,1405.* Or circle Reader Service No. 206.

QSO SOFTWARE

QSO Software's new program, QSO Comp-Troller™, provides the ultimate companion for controlling your late model Kenwood radio. It is composed of two programs, one for the Macintosh and one for MS-DOS machines. It will manage the interface between you and any Kenwood transceiver that supports the IF-232C interface. Frequencies can be directly inputted by clicking on the VFO, Memory, or SubBand, then keying in the new frequency or modifying the existing one. Memories can be read from the transceiver and stored on disk or read from disk and transmitted to the transceiver. The program also keeps track of any adjustments made directly on the rig and reflects them on the computer display.

The suggested retail price for the QSO Comp-Troller is $99.55. For more information, contact *QSO Software, 208 Partridge Way, Kennett Sq. PA 19348; (215) 347-2109.* Or circle Reader Service number 207.

Laser Communication Systems

This month I will continue detailing construction of a complete laser communications system. Last month I went over the basic power supply tor the HeNe (Helium Neon) laser that serves as system transmitter. This month we will get into the parts needed to construct a light detector coupled into a high gain audio amplifier to serve as system receiver.

The optical detector converts the laser beam into a signal coupled to the audio amplifier. A 12 volt muffin fan modulates the transmitter by passing the laser beam through the spinning blades. The fan blades, spinning at about 1 kHz, chop the beam into segments, which the receiver detects.

We can refine the audio amplifier design, but we must stop at some point for stability. Additional system gain can be obtained by optical gain, using a telescope or, in our case, a large fresnel lens which locuses energy onto the detector element, converting light to a DC current.

The Amplifier (Receiver) Circuitry

The audio amplifier circuitry is shown in Figure 1. From the gain potentiometer (10k) to audio out, it is nothing more than a basic audio amplifier. The first stage is quite special as it provides gain al 1 kHz which is centered aboul the transmitter audio frequency. This is due to the feedback network between pins 8 and 9. Initial tests showed that light sources such as argon and sodium lamps gave off a 60 Hz hum when the detector was pointed in their direction. The feedback circuit did well in limiting the hum, saving our eardrums.

The pin diode detector is the current-feed to the op amp. If all is working well, when you point the detector at a neon lamp you will hear a 60 Hz hum in your system. If your laser is operational, being chopped by the muffin fan, you will hear the 1000 hertz tone.

Don't point the laser at the detector; point it at some distant object—say, the end of your work bench, and point the detector in the same direction. As your lens and system become more sensitive. this distance can be increased.

A Few Basics

The frequency of a HeNe laser is 632.8 nanometers or 6328 angstroms. One angstrom is equal to one ten-thousandth of a micrometer. If you want to work that out to frequency, it comes to 474 THz, or 474,083 GHz if you prefer. This frequency of light is in the visible spectrum, and appears as an intensely bright red beam. Most supermarket bar code scanners use HeNe lasers, which suggests a source for surplus.

The word "laser" originated as an acronym for "Light Amplification by Stimulated Emission of Radiation." HeNe lasers are composed of a glass tube filled with a gas mixture. High voltage (around 10 kV) impressed across two electrodes is necessary for initial ignition of this gas, and 1500 to 2500 volts is necessary to maintain operation. The lasing action takes place in a fine capillary tube housed inside the main tube. The open end of the capillary tube is pointed towards the output or partially reflective mirror end of the laser.

Buying Lasers

Lasers can be purchased in two forms: plasma tubes or heads. A plasma tube is a laser with just the glass envelope. A laser head is a plasma lube mounted inside a metal tube with a high voltage cable and connector attached. Usually a ballast resistor, located inside the tube, comes as part of the "head."

You should check to determine if your head has a ballast resistor. THIS IS A VERY IMPORTANT STEP. If you try to connect a power supply and there is no ballast resistor on the head, you may damage the tube if the current flow is higher than normal.

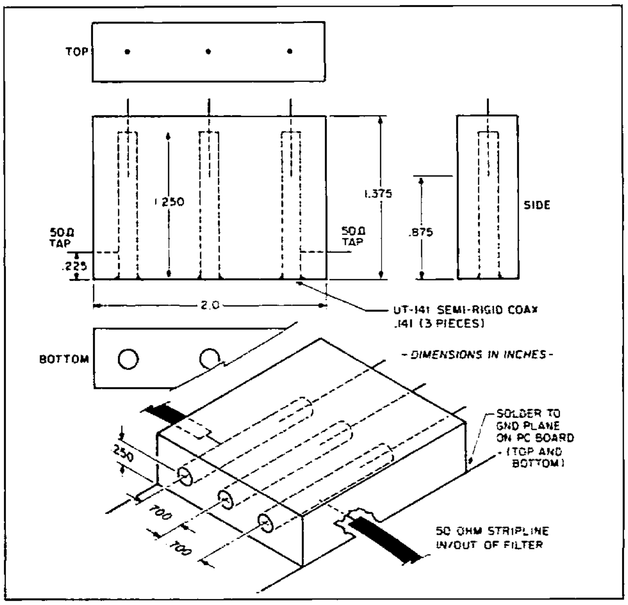

Figure 2. Filter for 1296 MHz using 0.141" rigid coax. Three dB bandwidth of 14 MHz. Ten dB bandwidth of 28 MHz. Total loss through the filter is 2 dB. (Construction details by Chip Angle N6CA.)

If in doubt about whether your head has a ballast resistor, you can add one before you do your first test. You can always remove it if it's not needed. The idea is to limit current to the tube. Insufficient current does no harm. A 10 mW laser requires about 6 to 7 mA, while a 2 to 3 mW laser needs only a few mA. My laser, obtained from a junk high speed commercial printer, has a power output of 10 mW. This makes it a class III laser, since the output is between one to several hundred mW.

BE VERY CAREFUL. Looking into any laser, particularly a class III, can cause eye damage. Believe me, this beam is extremely bright. Looking at it from the side, you may think it's not lhat bright, but trust me: It is. Also, though its spot size is small, beware of looking at its reflection. This can cause discomfort.

I found a supplier for lasers and laser power supplies that is quite reasonable: Karl Gedeon, P.O. Box 2336, Stanford CA 94309. A complete 10 mW laser head and 12 volt power supply from Karl cost only $100, and 2 to 3 mW lasers are quite a bit less. He also stocks laser related components, including laser pointers in the 2 to 3 mW range (small) and higher power pointers. I purchased a system from him and was very pleased. He also has 2 to 4 mW pointers, all operating from 12 volts DC.

In our first experiment, we used a laser transmitting over a two mile plus path with the beam so bright at the receive site that it appeared to be four city blocks on fire. There was not a city light, even at a nearby shopping center complex with all the sodium parking lights on, that could give a comparable brightness on the horizon. Only the street light nearby was comparable, but it wasn't as bright as the laser. At this two-mile distance, the 1 milliradian spot size (at the transmitter) had increased to a 5-foot wide spot.

Set-Up and Testing Details

Let's get into the details of the system that Kerry N6IZW and I put together for the test just described. The laser power supply was operated from the 110 VAC mains, so it remained at Kerry's home. Modulation of the laser was done with a 12 volt DC muffin fan. The receiver was a photo PIN detector salvaged from scrap medical equipment. The detector was tied to a current amplifier for a first stage to give low noise amplification of the signal coming from the detector. The remaining circuitry is an audio amplifier that amplifies lhe 1000 Hz modulation from the transmitter.

Many different types of lenses were employed on a hand-held optical bench to evaluate the performance of the test lens and the detector. It was found that a Radio Shack "cigarette" parabolic reflector about three inches

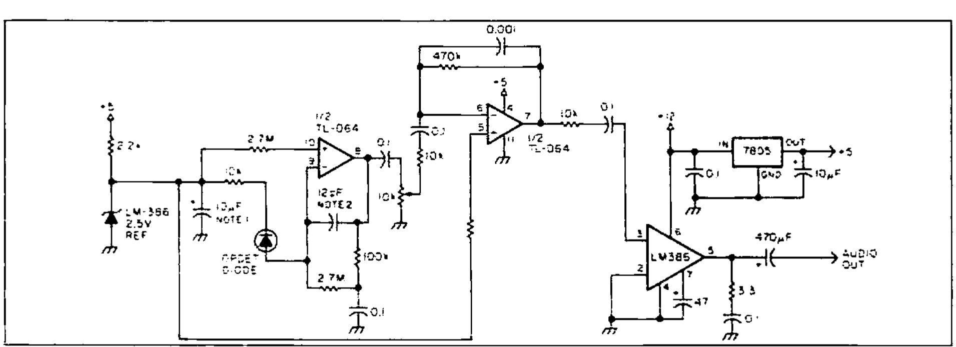

Figure 1. The Laser receive system. Note 1: The 10 µF capacitor removes the low frequency component (AC) from the optodetector. Note 2: The 12 pF capacitor on the first stage of the TL-064 prevents oscillations and improves stability. Note 3: Adjust the feedback network on the first stage of the TL-064 to maximize at your frequency (approx. 1 kHz). Response is broadband in nature.

in diameter would give a good signal, focusing the laser beam into the detector. Several other items were tried, including a magnifying mirror, and they all worked. The larger the "lens," the better the light gathering or total system gain.

Then we tried an 8" x 10" fresnel lens, not a high quality type, but rather one intended for magnifying print for reading, with a focal length of 10 to 11 inches. The best part of this lens was the cost, $1.50 at most stationery stores. It worked super.

Kerry found a plastic trash can at a local store and mounted the lens on the open end, and placed the detector on the center bottom. The lens was built out a little bit to achieve proper focus depth to the diode. In initial tests with this detector system, we were able to detect the reflection from the laser at almost anything we were able to see. The spot was reflected off of trees and wires at half a mile and more.

Improvements

This proved to be an excellent test because it was so simple and gave positive results of sensitivity and system evaluation. Several improvements were made, pushing the reflection detection range further out. The first modification pushed the range out to over 1000 feet. Street lighting created 60 Hz interference and high level annoyance in our ears. The feedback scheme to solve this, mentioned earlier, was developed by Kerry N6IZW. It worked so well I could not believe it. This mod pushed the detection range to just perceivable light reflections with the trash can and fresnel lens system.

This system was so sensitive that we could point the detector skyward and detect other interesting noises. One noise source was aircraft strobe lights. They sounded like a dull *thud, thud* at the strobe rate. When the aircraft was prop driven, and its attitude just right, we could hear the running lights being chopped by the propellers at a high audio rate. No noise came from incandescent lighting, however fluorescent, sodium, and similar type streetlights would project at the AC switching rate. This was plainly heard on the headsets. These lights could be picked up many miles away.

Even during very heavy cloud cover on a pitch black night, Kerry was able to hear the strobe of an aircraft. Pointing was not critical, as the cloud cover defused the strobe light. He could not see the light visually, which illustrates the system's sensitivity.

The PIN photodetector system is quite easy to use. With minor circuit changes, other types of detectors could be used. The trade-off is sensitivity. There are photo transistors, photoresistive cells, and photo darlingtons, as well as photo FETs. These are all sensitive, but one device that shines better than most is the *photo multiplier tube*.

The PIN diode is quite good, but the photo multiplier is superior and easier to find in surplus. One difficulty with the PMT, however, is that it requires a high voltage power supply operating at 1000 volts with 2 or 3 mA. I will get into the PMT next month and try to give you enough details to construct a very good system from the junk box.

Mailbox

Jim WA9PYH is looking for information using stripline techniques to construct a filter for use at 1553.5 MHz. He wonders what length a stripline should be to resonate at a particular frequency. Well, most stripline filters are made with 50 ohm transmission lines on 0.062 PC board, making line width about 0.100 inch (G-10 glass epoxy) and 1/4 wavelength long.

Now, the trick is that the actual length (1/4 wavelength) is modified by the velocity factor of the dielectric material, and any external or tuning capacitor. The velocity factor for G-10 PC board material runs from 0.50 to about 0.57. This factor is multiplied by the 1/4 wavelength to arrive at the actual line length. The line is or should be near resonance as it sits. Normally, 1/2 wave lines are used for filters coupling in and out with 1/4 wave sections.

Additional tuning elements shorten the line sections quite a bit, and can factor up to 0.5 to 0.6 or more, depending on type. In a filter for 1152 MHz, the line length is about 0.400 inches long. Tuning is done with a 5 pF variable capacitor to ground. So you see just how short this filter is by adding a capacitor to tune the stripline. Don't forget to couple in and out of the line at the 50 ohm point, which is 20% to 35% up the stripline from the the grounded end.

I sent Jim a few other design notes on other filters I have tried, including one that used 0.141 rigid coax to construct a very good filter for 1296 MHz. This design was first spotted in a note from Chip N6CA for 1296 MHz, several years ago. He had taken short sections of 0.141 hardline and positioned four of them in an enclosure, feeding them with stripline in and out of the filter. Tuning was accomplished by pulling the center of the coax out of the far wall of the filter through a good ground connection. This formed a capacitor with the 0.141 hardline. When the frequency was properly set, the center of the coax was soldered to the cover housing the filter. See Figure 2 for construction details.

Bill N6OLD writes about his 24 GHz operations. His recent contact might be a record; if not, it's certainly quite an accomplishment. On February 23, 1991 at 5:25 p.m., KK6T/6 (ex WB6HLC) and N6OLD made an SSB contact between Hull Mountain CM89MM (6100 feet) and Mount Diablo CM97BV (3800 feet), covering a distance of 125 miles. KK6TG's equipment was an 18-inch dish and a 14 dB noise figure pre-amplifier capable of +7 dB output power on transmit. N6OLD sported a 20-inch dish, 12 dB noise figure pre-amplifier and about +2 dB output power.

An earlier test at 2:32 p.m. between another site and Mount Diablo revealed stronger than expected signals, 40 dB out of the noise, so a longer shot was tried. The Hull Mountain shot had an even stronger signal, which suggests ducting. The low humidity (16% R. H., 50 degrees F) also helped.

Note that 24 GHz operations are right in the water absorption band, making attenuation to 24 Ghz operations higher. For least attenuation, it's best to operate when humidity levels are low. Bill is currently exploring water absorption effects and investigating propagation in this interesting (24 GHz) band.

Next month I will cover the PMT in more detail. As always, I will try to answer your questions about microwave and related topics. Please send an SASE for a prompt reply. 73s, Chuck WB6IGP

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
6 Jenny Lane
Baltimore, MD 21208

Back to the Beginning

With appropriate ruffles and flourishes, I am pleased to note that this month begins the 15th year of "RTTY Loop"! Rather than wax nostalgic, as I often do at anniversaries, let me just say that this column has covered a lot of ground these many years, and has evolved in more ways than one.

This month, to start out, I'd like to drop back to a basic question. This was prompted by a letter from Gregory McIntire KE0UV of Belle Fourche, South Dakota, that surfaced from the stack on my desk. It's one of the "Oh, I know the answer to this" questions that soon becomes mired in too many answers.

Gregory would like to know how to determine the exact frequency that a RTTY, AMTOR, or packet station is operating on.

Exploring the Question

To quote KE0UV: "When operating CW, I think there is little question of what the operating frequency is. Whether the digital display of a transmitter is accurate or not, I think that it is understood that the frequency of operation is the actual and exact radio frequency which is radiating from the antenna. When operating SSB phone, the actual frequency radiating from the antenna varies with the modulating audio. So, we designate the 'operating frequency' as the frequency of the suppressed carrier. This 'suppressed carrier' frequency does not ever radiate from the antenna during an SSB phone transmission, though. Nevertheless, we specify the particular sideband along with the suppressed carrier frequency as the frequency of operation. But when it comes to the FSK modes, there seem to be differing opinions.

"Some rigs use two audio tones generated by a modem (TU), fed into the mike jack, in SSB mode (usually LSB) to generate FSK at radio frequency. When this method is employed, and using LSB, the two RF frequencies radiating from the antenna are the 'suppressed carrier' frequency minus the two audio frequencies. This means that the higher audio tone will create the lower RF frequency, and vice versa. If the two audio tones used are 2295 Hz and 2125 Hz, and the suppressed carrier frequency is set at 14.100 MHz (LSB), then the two RF frequencies will be 14.097705 MHz and 14.097875 MHz. If we use the LSMFT rule [Low Space Means Fine Teletype], the higher audio tone generated in the modem causes the lower RF, or space frequency, to radiate from the antenna.

"Other rigs use a direct FSK scheme which does not use SSB. The modem or terminal unit simply sends a high or low voltage to determine whether to transmit the higher or the lower radio frequency. This would be the same as two different CW signals transmitted alternately. It is my understanding that some transceivers, in FSK mode, display the lower RF at the digital readout, while others display the higher frequency as the frequency of operation.

"It has been my personal experience that many, if not most, hams determine their frequency of operation to be that which the digital readout is displaying during transmission, regardless of which of the two types of signal generation is employed. Using the 'two audio tones into LSB' (often referred to as AFSK) method, the actual frequency radiating from the antenna could be 2.295 kHz (or more) lower than what the readout is displaying. Conversely, using the so-called 'direct FSK' method, the readout should display one of the two RF frequencies correctly.

"Anyway, back to my question. What is the correct designation of a two-tone, RTTY, AMTOR, or packet operating frequency? The lower radio frequency, the higher radio frequency, the suppressed carrier frequency, or none of these?"

Gregory, I really think this is a landmark question. It has advocates on all sides. I turn it over to the readership—to all of you—for input, and look forward to forming some kind of consensus. Who knows, maybe we will even turn this into some form of necessary standard! At any rate, readers are invited to send their votes and opinions to me, at the designated address, for inclusion in a future column.

More Questions and Answers

Always looking forward to a view of another ham's messy shack, I appreciate the photo of Michael Freedman VE3BGE, hailing from Toronto, which I share with you all herewith. His station sports an impressive assortment of radio gear. Looks good, Michael, and thanks for the photo. Sure folks, go ahead and send me photos of your junk, too. You never know just what you'll find in "RTTY Loop"!

Back in February 1991, I passed along Norm WJ5Z's request for a Morse code copying program for the Color Computer. Ed Tyson N5JTY of Alamogordo, New Mexico, reached back into his memory cells for the answer. In December 1982, the late *80 Micro* published an article called "CC CQ," by Michael Chuck of Severna Park, Maryland. In this article, a transmitting and receiving Morse terminal for the CoCo is described.

The article, which also includes a complete listing for a program to accomplish the task, is far too long to reprint here. If you insist, and cannot dredge up a copy anyplace else, I can be persuaded to send you a copy, for the customary $2 and a LARGE self-addressed, stamped envelope with two ounces' worth of postage.

Last for this month, thanks to Domenic M. Mallozzi N1DM of Watertown, Massachusetts, for a comment he sent me. Dom recalls my question regarding mechanical teleprinters, and states that his station "... is a Model 15 page printer [he has both a commercial and a military version], a HAL ST5K demodulator, and a home-brew AFSK running into an old Heath HW-101 transceiver."

Dom also notes that he has "about 100 QSOs on RTTY from W1AW over the past ten years.... Don't know if the visitor's RTTY position exists in the new station, but I hope so. One of the operators there told me that very few visitors ask to operate RTTY. He said he could only remember two others in the last five years."

I'm fairly caught up with responses to your questions, and with requests for copies of the programs recently described. If you have not heard from me within a month or so of your letter, odds are that I did not receive the initial question. As always, direct your comments, questions, suggestions, and barbs to me at the above address, or via CompuServe (ppn 75036,2501) or Delphi (username MARCWA3AJR). I look forward to hearing from you in this, the 15th year of RTTY Loop.

Michael Freedman VE3BGE, from Toronto.

DEALER DIRECTORY

DELAWARE

New Castle

Factory authorized dealer! Yaesu, ICOM, Kenwood, Ten-Tec, AEA, Kantronics, DRSI Mfg., Ameritron, Cushcraft, HyGain, Heath Amateur Radio, Heil Sound. **DELAWARE AMATEUR SUPPLY, 71 Meadow Road, New Castle DE 19720. (302) 328-7728.**

IDAHO

Preston

Ross WB7BYZ has the largest stock of amateur gear in the intermountain West and the best prices. Over 9,000 ham related gear in stock. Call us for "all" your ham needs today. **ROSS DISTRIBUTING CO., 78 S. State, Preston ID 83263. (208) 852-0830.**

NEW JERSEY

Park Ridge

North Jersey's oldest and finest Shortwave and Ham Radio Dealer. 1½ miles from Garden State Parkway. Authorized Dealers for AEA, Kenwood, Japan Radio Company, ICOM, Yaesu, etc. Ham Sales, Lee WK2T. **GILFER SHORTWAVE, 52 Park Ave., Park Ridge NJ 07656. (201) 391-7887.**

NEW YORK

Jamestown

Western New York's finest amateur radio dealer featuring ICOM–Larsen–AEA–Hamtronics–Astron. New and used gear. 8 a.m. to 5:30 p.m., Sat. and Sun. by appointment. **VHP COMMUNICATIONS, 280 Tiffany Ave., Jamestown NY 14701. (716) 664-6345.** Circle Reader Service number 129 for more information.

Manhattan

Manhattan's largest and only ham and business Radio Store. Featuring MOTOROLA, ICOM, KENWOOD, YAESU, AEA, SONY, PANASONIC, MFJ, GBC CLOSED CIRCUIT TV CAMERAS AND MONITORS, BIRD WATTMETERS, OPTO ELECTRONICS FREQUENCY COUNTERS, AOR SCANNERS, TEN-TEC, ETC. Full stock of radios and accessories. Repair lab on premises. Open 7 days. M–F, 9–6 p.m.; Sat. & Sun., 10–5 p.m. We ship *Worldwide*. For Specific information call or write: **BARRY ELECTRONICS, 512 Broadway, New York NY 10012. (212) 925-7000. FAX (212) 925-7001.**

OHIO

Columbus

Central Ohio's full-line authorized dealer for Kenwood, ICOM, Yaesu, Alinco, Info-Tech, Japan Radio, AEA, Cushcraft, Hustler, and Butternut. New and used equipment on display and operational in our 4000 sq. ft. store. Large SWL department, too. **UNIVERSAL RADIO, 1280 Aida Drive, Reynoldsburg (Columbus) OH 43068. (614) 866-4267.**

PENNSYLVANIA

Trevose

Authorized factory sales and service. KENWOOD, ICOM, YAESU, featuring AMERITRON, B&W, MFJ, HYGAIN, KLM, CUSHCRAFT, HUSTLER, KANTRONICS, AEA, VIBROPLEX, HEIL, CALLBOOK, ARRL Publications, and much more. **HAMTRONICS, INC., 4033 Brownsville Road, Trevose PA 19047. (215) 357-1400. FAX (215) 355-8958. Sales Order 1-800-426-2820.** Circle Reader Service 298 for more information.

DEALERS: Your company name and message can contain up to 50 words for as little as $420 yearly (prepaid), or $210 for six months (prepaid). No mention of mail-order business please. Directory text and payment must reach us 60 days in advance of publication. For example, advertising for the April '91 issue must be in our hands by February 1st. Mail to *73 Amateur Radio Today*, Box 278, Forest Road, Hancock NH 03449.

Quorum introduces the first totally integrated system for the reception of weather satellite images directly on your personal computer. Selection of HF NAFAX, GOES WEFAX, GOESTAP, METEOSAT, NOAA and METEOR APT (including satellite downlink frequency selection) are made under complete program control from your PC keyboard.

The easy to learn and use Menu driven program allows you to capture, store, retrieve, view and print images with a few simple keystrokes. Images can be colorized from a palette of up to 262,000 colors when using a VGA display.

System configurations capable of NAFAX reception start at $399.00 while fully capable systems can be configured for $1500 to $2000, providing professional quality at low prices.

For complete information and a Demo Disk, call or write:

Quorum Communications, Inc., 1020 S. Main St. Suite A, Grapevine, TX 76051 (817) 488-4861. Or, download a demo from our Bulletin Board by calling (817) 421-0228 using 2400 baud, 8 data bits and No parity.

Receive Weather Satellite Images and Charts on your PC with Quorum's Totally Integrated and Affordable Weather Facsimile System

Never Say Die

Continued from page 4

you about my getting on 75m to give some of the DXers a new one and couldn't find one single taker? The nets told me to get off the frequency because my signal wasn't strong enough to bother listening to. Okay, so I've told you about that.

One fact of life is that either you have some goals and excitement or you're going to vegetate and die. No, I'm not suggesting you get involved with DXing; we're already up to here with those ruthless fanatics. We do need a lot more DXpeditioners. We need more experimenters to pioneer new modes. We need more packet ops. But mostly, and by a wide margin, we need kids. So spend some time and go out there and poison their dirty little minds with the glories of hamming. Lie a little. Get 'em to come over to your shack.

Now wait a minute. When you get 'em into your shack I don't want to hear that you fired up and made a couple CW contacts while they got bored out of their gourds. Find something interesting for them. . . if you can. Can you show them some packet? How about a few slow-scan pictures from some weird country they've probably never even heard of?

Then tell them about the fun you've had on hidden transmitter hunts. Tell 'em about Dayton and its endless flea market. Tell 'em about Dayton and 30,000 hams, all with HTs on their belts, all squawking away at once.

Tell 'em about your local club meetings where a few old-timers do everything in their power to make it miserable for kids. No, better not tell 'em about your club meetings with endless and pointless business discussions over total trivia, followed by a lack of an interesting speaker. Maybe they'll come for the doughnuts and die of cholesterol.

A chap who runs a happiness radio program out in Michigan somehow got hold of me and got me to talk over the air about happiness. Now I may grouse in my editorials, but that's just my futile effort to whip you out of your rut and keep you alive a little longer. The fact is that I'm having a ball. You know my goals. . . like helping the music industry to grow and revamping the American educational mess so we'll have ten million excited young hams instead of a few hundred doddering old codgers whining and kvetching on our bands.

I'm having funl Every day is a challenge. I wake up around 4 or 5 a.m., shuffle into my office across the hall and start answering my mail, writing editorials for a dozen or so publications, doing business plans for new publications, and so on. Pretty soon it's 7 a.m. and time for breakfast and a check on the news. Hmmm, the news is lousy. Wars, civil and uncivil, in a couple dozen countries. . . many of which I've visited and operated from. Starving children. Refugees. Enough of that stuff. . . perhaps it's time to write King Hussein and tell him how to fix the Palestinian mess. Or give Bush some guidelines on new approaches to education. . . he sure could use 'em.

Naw, there's still a stack of mail I haven't answered. Some chap in Poland loves my music magazine and wants to be an Eastern Europe correspondent. A chap in Sabah wants to open a CD store. Another wants my opinion of his Portuguese organ music CD. Two responses to my call for ham industry people to volunteer to go to Washington with me to talk with the Commissioners and answer their questions about amateur radio.

If happiness helps keep people alive, which I think has been rather well documented, then you're going to be reading my editorials for a long time to come. I'm having a ball. My only major problem is in finding a few more competent and enthusiastic people to help me have fun. That's a downer. . . but it's compensated for by the wonderful group of people I've already got working with me. And best of all are the letters from readers. Those I love.

73 readers write to tell me they're having fun as a result of this or that article. Or that they've taken off 85 pounds, just like I did. Or that they've gotten a dozen new youngsters licensed. My *CD Review* readers write to thank me for getting them interested in some new kind of music. . . like ragtime. . . telling me how much enjoyment they're getting from reading the magazine. I love hearing from advertisers telling me how well their ads are doing for them.

I love visiting schools and teaching youngsters about amateur radio and entrepreneurialism. I love letters saying, hey you were right about packet, RTTY and so on. Retire? You're kidding! I've got too much to do. And so do you.

Those Damned Japanese?

Are you still grousing about the Japanese? About how they came along and grabbed our consumer electronics industry and parlayed it into dominating the whole financial world? About how they're buying New York and Hollywood? About how they now dominate our movie and music industries as well as every aspect of consumer electronics?

Well, I suppose some myopia helps keep us from blaming ourselves. You should see the angry letters I've gotten from automobile union members when I groused about Detroit cars recentlyl Actually, if you want to blame someone, why not pick on Ed Demming, the chap that Japan listened to and we ignored? Ed preached quality and Japan bought the idea. They imported Ed and got him to preach from one end of Japan to the other. . . and even better, they listened and did what he said.

Ed tried to sell the idea of quality here in America and was told to shut up. Alas, the concept is still alien here. I find myself driving Detroitmobiles when I rent cars on trips, so I know how they compare with my Toyota Previa. Other than being brainwashed by enormous advertising budgets and lavish rebates, I don't see why people are buying Buicks. Quality? Har de harl

Sure, my father bought Fords in the '30s and I followed suit, but when I discovered the Porsche Speedster in 1957, that was the end for Detroit. I tried a Dodge van in the '70s and had so much trouble no power on earth would ever get me near a Chrysler product again. The dealer screwed me. Chrysler could care less. My van would stall and not be restartable without pouring gas directly into the carburetor. A ham friend dug up a confidential factory notice to dealers admitting the problem and the lack of a known repair to fix it.

I find my own organization ignoring quality, despite my constant preaching and fussing. The company that handles our subscription list manages to send renewal letters in the wrong order or at the wrong time. They send renewal #4 for the first renewal effort. Subscribers tend to get furious when they get word that their subscription has already lapsed.

So what can we do? It still takes too big a computer for us to do the work ourselves. In another year I think there will be some software available that may allow us to handle our own circulation fulfillment with a super-microcomputer. I sure hope so.

The basic problem seems to be an American lack of thinking in terms of the importance of quality. We give lip service to the customer being right, but when we are dealing with a customer many of us tend to forget their perspective and just think of how much trouble this is for us.

More than one *73* editor has gotten his walking papers when I found, after many warnings, that he was still making authors wait for weeks to get a response. And I found a customer service person who had a switch installed to turn off the bell on her phone so she wouldn't be disturbed by complaints.

A good deal of this comes down to the kind of education we're providing. By the time our kids are in the work force it's too late. So we put up with toys that break, cars with doors that don't fit and engines that won't start.

To the Detroit workers who bitched to me about my love of Japanese (and German and Swedish) cars, I say take a look at the recent *Consumer Reports* issue that listed the repair records for all cars. The Detroit cars are a disgrace compared to most foreign cars.

Yes, it's difficult to adjust to the encroaching world economy. We've been so steeped in nationalism all our lives that we can't really understand about things being made where it's the cheapest to make them. Today we have products where parts are made in Singapore, parts in Japan, and assembly is in Mexico. How do we cope with that? How do we educate our children to come out on top? Blue collar jobs are going away to lower wage countries as communications and transportation costs drop. Technology is in the driver's seat, not the farmer or the factory worker. Yet we're letting our kids grow up technological illiterates. Yes, I know, we're too busy watching a ball game on TV, so we'll leave it up to our schools to teach our kids. That's not our responsibility any more.

And look at the fantastic socialist system we've built to teach our kids. We tax the heck out of ourselves and ignore that most of the money gets lost in the socialist bureaucracy and that only about 10% dribbles down to the kids. When we find it isn't working we ask for more money to feed the bureaucracy. It responds by adding more bureaucrats and 9% dribbling down to the kids. Parkinson wrote an expose of this syndrome back in the 1950s. Nothing has changed.

What's this got to do with amateur radio? Presumably you come out of the hamshack sometime and have thus, even if accidentally, procreated some kids. Well, how many of them are active amateurs? How many are gung-ho for a high-tech career? And who won the pennant in 1984?

If the schools stink, how about teaching your kids yourself? I'd love to see some articles on how to suck our kids into hamming. If you even give a hint that you care, your kids will avoid hamming like the plague, so it isn't easy. The trouble is you have to be smarter than they are. Also, they have full time to devote to frustrating you and you only have part time to con them. Any helpful hints?

If you are able to get by their guard and get 'em interested in hamming you'll have done them the best favor you could. They'll be on the road toward learning about technology and that will quickly separate them from the kids who will never even have a chance at making it beyond winning a state megabucks lottery.

If it's too late to con your own kids, perhaps you can lay some traps for your grandchildren. Or get to work in a local school and sow your seeds. You won't get much thanks and you won't get a nickel, but if there's a ledger up there, you're going to find some gold stars on it when you get your Silent Key certificate. I think there's a ledger.

So I Screwed Up... What's New?

I was just sending in a classified ad to the *Mensa Bulletin* to see if I could suck some high IQ youngsters into our hobby via *Radio Fun*. That got me to thinking... always a dangerous situation.

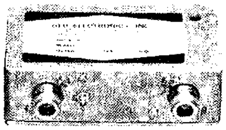
Five of us first members of Mensa in America got together in 1960 and formed American Mensa. I volunteered to be the secretary since I was just starting *73* and thus had a Ditto machine to print meeting notices and the addressing equipment to maintain the mailing list.

A couple years ago a reader claimed I wasn't really a founder of Mensa, but the official Mensa history printed last year finally set the record straight. I'm not sure I can claim much credit... I was in the right place at the right time... and more of a doer than the others at the meeting.

Where I screwed up, in retrospect, was in not taking the bull by the horns and running with the organization. I let my first wife convince me that I had

HIGH PERFORMANCE PRESELECTOR-PREAMP

The solution to most interference, intermod, and desense problems in repeater systems.

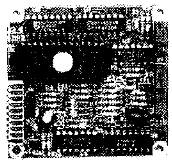


- •40 to 1000 Mhz tuned to your frequency
- •5 large helical resonators
- •Very high rejection
- •Low noise—high overload resistance
- •8 db gain—ultimate rejection >80 db
- •GaAs fet option (above 200 Mhz)
- •Cast aluminum enclosure
- •N, BNC, and SO239 connector options

Typical rejection:
±600Khz @ 145 Mhz: 28db
±1.6 Mhz @ 220 Mhz: 40db (44db GaAs) ±20 Mhz @ 800 Mhz: 65db
± 5 Mhz @ 450 Mhz: 50db (60db GaAs) ±20 Mhz @ 950 Mhz: 70db

AUTOMATIC IDENTIFIERS

- •Up to 8 EPROM programmed messages
- •Adjustable audio, speed & interval timer
- •"ID over voice inhibit"
- •Low power option
- •Modular design
- •Message selection via binary input—TTL levels
- •Size: 2.7 x 2.6 x 0.7"



NEW Model ID-2B

The ID-2B provides required station identification without troublesome diode programming. The "ID over voice inhibit" circuitry allows for courteous operation by not allowing an ID until the next squelch closing.

ID-2B Wired/Tested $99.95 **ID-2B-LP Low Power $109.95**

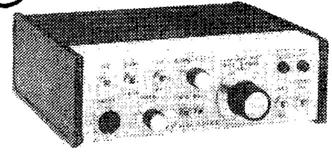
AMATEUR TELEVISION

SMILE! YOU'RE ON TV



Only $329

Designed and built in the USA
Value + Quality from over 25years in ATV...W6ORG

With our all in one box TC70-1 70cm ATV Transceiver you can easily transmit and receive live action color and sound video just like broadcast TV. Use any home TV camera or VCR by plugging the composite video and audio into the front VHS 10 pin or rear phono jacks. Add 70cm antenna, coax, 13.8 Vdc and TV set and you are on the air...it's that easy!

TC70-1 has >1 watt p.e.p. with one xtal on 439.25, 434.0 or 426.25 MHz, runs on 12-14 Vdc @ .5A, and hot GaAsfet downconverter tunes whole 420-450 MHz band down to ch3. Shielded cabinet only 7x7x2.5". Transmitters sold only to licensed amateurs, for legal purposes, verified in the latest Callbook or with copy of license sent with order.

Call or write now for our complete ATV catalog including downconverters, transceivers, linear amps, and antennas for the 70, 33, & 23cm bands.

more than enough to do starting *73*, helping to run the 1960 ARRL Convention in New York and being president of the Porsche Club. Other than damn near killing me . . . twice, I've been trying to remember what good my first wife did for me. I'll keep working on it, there must have been some good in there somewhere.

It just seems a rotten shame to have a high IQ group that has no purpose and is contributing nothing to the world. What a waste! There are chapters all around the world, but they don't even communicate with each other, so even that's a waste. Phooey.

Yes, I was up to here getting *73* started. I was raising hell with every ham author I knew to get construction articles written for the magazine. I was pestering every ham club in the country for subscriptions. I was trying to convince the over 850 ham stores we had then (before ARRL's Incentive Licensing) to sell the magazine. I also had to do all the editing, take the photographs, make all the advertising sales, proof the typesetting, do the page layouts, write and mail thousands of subscription letters, type subscription stencils, print out the subscriber wrappers, wrap 850 bundles for ham stores, bill the advertisers and ham stores, and keep the books. I was a one-man magazine publishing company with just barely enough money to print the first issue, so I had no margin for error.

As the Porsche Club president I kept the membership list, sent out meeting notices, ran the monthly meetings, laid out and ran some rallies they'll never forget, helped with timing trials and ran gymkhanas. I still have the electronic stopwatch I built for the timing trials. Oh yes, I converted a bunch of surplus radios to push-button tune the time standard broadcasts on 3.333, 5.000, 7.335 and 10.000 kHz for our rally check points.

I was also running Radio Bookshop, selling dozens of ham and electronics books by mail, plus a complete line of rally calculators, computers, watches and accessories that I advertised in the car magazines.

Then there was that ARRL Convention. I'll never forget the big banquet where a fathead future ARRL president publicly congratulated himself over the success of the convention . . . while Chet K2EAF and I sat there knowing we had done virtually all the work. We'd sold all the booths to the exhibitors, printed and sent out the posters to ham stores, written and sent out mailings to the Hudson Division members and so on. Oh well, I really shouldn't complain. I learned how to put on a convention and fathead didn't. That experience was priceless for me in 1978 when I organized and ran an enormous microcomputer show in Boston.

On the down side, if I'd gotten more embroiled in Mensa in 1961 I might not have moved to New Hampshire in 1962 . . . one of the smarter moves I've made. Too, Mensa got all messed up with some ridiculous ego clashes in the mid '60s. A few members thought Mensa was really important. Well, we have hams who think working 350 countries is important, so who are we to throw stones? I happen to think being on the DX honor roll is about like owning a Cadillac, one of America's answers to an inferiority complex. No, I've never submitted my cards for DXCC. I've never even been a fanatic about getting cards. If they come, fine. If not, so what? My fun is in talking with people and I particularly enjoy talking to unusual places. I usually call "CQDX" and let 'em call me.

I avoid pile-ups and lists most of the time . . . unless I'm DXpeditioning. Then I have my own system where I use one frequency and knock off contacts faster than any other way I've tried or heard. I work 'em right on down to the mobiles and QRP rigs without making a mess of the band. When I'm home, I prefer talking. When I'm DXpeditioning, I play the instant QSO game.

What would I have done with Mensa if I'd taken it over? Well, first of all, I'd have established some goals for it . . . a mission. Being the exclusive snob group it's become wouldn't have been on the list. When I've mentioned Mensa in my editorials before, I've always pointed out for the jealous—who reactively hate anyone smart or rich—that being smart doesn't really mean much. There's no correlation between IQ and success. It mostly means they can do well on IQ tests. Big deal.

Individual high IQ people people seem to be born with a better brain than others. Alas, that doesn't mean they know more. Indeed, think of your brain as a super computer, for that's what it is. You should know enough about computers by now to know that the hardware, no matter how wonderful, is completely useless without good software. Programming. Well, programming is what your parents, family, friends and teachers put in. But the hardware and software only provide you with an operating system; you still can't do anything with it without data. We get data through TV, books, magazines, and through everyday living. Where so many high IQ people fall short is in their early programming, their lack of data, and their having a whole bunch of bogus data screwing things up. Garbage in, garbage out, in computer terms.

Sure, we learn things. We pick up all sorts of data. But how can we know what is true and what is garbage . . . like sitcoms, soaps and sports? My solution to that is to get a high IQ group together and let the law of averages limit the worst of the bad data. This is where I think Mensa had a great potential. The very diversity of experience, data and programming would tend to cancel out much of the garbage.

So, if I'd have run Mensa I'd have organized conferences aimed to help solve government and industry problems. Even 20 high IQ people with 20 backgrounds and 20 fields of expertise would be one heck of a think-tank resource. And, unlike our commercial think tanks, it wouldn't have to make money.

What use is there of our having a bunch of smart people if we don't use them to help us solve problems? They're sure not going to go into politics . . . they're too smart for that. Heck, if we gave Mensans something creative to do we might even attract more successful high IQ people to the organization. As it is, a minuscule percentage of Mensans are outstandingly successful. Outside of Don Peterson, who was recently canned as president of Ford, I can't think of any successful members Mensa can brag about.

So I screwed up . . . too involved with temporary expediency to see the long-term picture. But, who knows, I might have succumbed to the usual Mensa hubris and rushed out to buy Bakker's Heritage Park and rename it Brainland.

You know, it doesn't take Mensan brains for a group to do a good job of tackling problems. You might want to try it with your ham club and see for yourself. Sure, you'll have some hams with strongly held opinions. That's when they've come to conclusions without positive knowledge. Some subjects are too ineffable to allow rational thought, such as religion and politics.

But it might be fun to pose some typical ham problems to the group and see how well they do in coming up with creative answers. Like what to do about the mess on 14.313 . . . or how to chill K1MAN cluttering up our bands with endless self-serving and even commercial, bulletin broadcasts. Or how your club can help get amateur radio growth going again. Or even how to get more local hams interested in your club.

Let me know how you make out. I think you'll be surprised.

Of course, instead of solving problems, you may end up with sessions like the McLaughlin Group on public television. I enjoy their opinionated approach, their grasp of complex problems, and their inability to even come close on their predictions.

Now The ULFs?

Some scientists have been having considerable success in predicting earthquakes by monitoring the ultra-low frequencies, down below one hertz. This sounds (?) like something some *73* readers might like to have a go at.

Building electromagnetic field detectors for the 0–1 hertz band certainly presents an interesting challenge. Some of the strongest signals seem to peak around 0.1 Hz. Let's see what you can come up with. Maybe we'll need a ULF column, if you start opening this band.

Dayton '91

Too bad if you missed out. The Dayton Hamvention is definitely the world's biggest ham toy store, and everything at a discount! It's two-and-a-half days long, and even so there's no way to see everything. By Saturday morning they had over 33,000 signed in. The huge Hara Arena parking lots and the fields around them as far as you could see were packed solid with cars, vans, pickups, RVs and campers, all bristling with antennas.

You see, they come in convoys from all over the country, each happily gabbing away on their own convoy channel . . . oddly like CBers. A modern version of the old Conestoga wagon trains that crossed the same plains 150 years ago. Instead of Indian arrows sticking out of the wagons, now it's antennas.

I'm not talking one or two, I'm talking mobile antenna farms that would make an AWACS plane envious. Some of them had to have had serious problems with overpasses. These convoys must have wiped out TV reception for whole towns as they passed through.

Imagine, if you will, 35,000 hams, all with at least one HT on their belt, all with their squelch breaking every few seconds. Many had two, three or even four HTs, one for each band so they wouldn't miss out on any bargains their convoy pals might find.

"Hey, here's a guy selling fax machines for $300! Brand new!" "Wait'll you see the Mac software I've found over here." Hams were excitedly carting boxes back to their cars all weekend. With 530 booths inside the arena and 2,276 flea market spaces, now how can anyone do a decent job of checking all that in the only 1,260 minutes the Hamvention is open? Well, 35,000 hams sure tried!

If you try to see 'em all, that means you've got to manage an average of 27 seconds per booth or flea market area . . . and that doesn't count any time waiting on the chow or portapotty lines. That doesn't even allow for any time spent attending any of the 55 forums . . . and they're one of the main reasons many drive or fly all that way.

They had forums for packet, AMSAT, county hunters, antennas, home-brewing, contests, Collins users, ARES, weather satellites, MARS, VHF, repeater coordination, OSSBN, 10/10, FCC, SSTV, Firebirds, SPAM, DX, Red Cross, ATV, bicycle hams, QRP, ARRL, scanners, and SWLs. There were forums on getting new hams, on recruiting kids, and many more technical forums.

Even K1MAN, obviously not totally satisfied with broadcasting on all bands day and night with his endless "bulletins," had a 90-minute forum. Oh darn, I forgot to go to that one!

Yes, there was an Uncle Wayne forum where I tried to keep a packed room awake and chuckling at our collective misfortunes. Alas, as usual it was like a sauna.

The most exciting part of the Hamvention for me is seeing the new equipment being exhibited. Much of the new gear is so complex that it takes an expert several minutes just to cover the basics. It made me wish there was some way to get across all this information in a product review. But there's so much to tell that we're talking about book-length reviews. You really have to see a lot of this stuff yourself and talk with the people who have designed it.

While another ham rag devotes its editorials to complaints about hamfest food, I still look forward to the Hamven-

tion BBO sandwich. Love it! The Hamvention committee sure is cheap with their refreshments for the exhibitors. There's some coffee and a supply of doughnuts which runs out in minutes. That's it. No cold drinks. No sandwiches. They are considerate in providing a special room where exhibitors can buy lunch instead of waiting on incredibly long lines. But they don't reckon with us notoriously tight Yankees. So I grumblingly shell out and buy a BBQ sandwich which I split with Sherry. Okay, I'm cheap . . would you rather I increased the *73* cover price and went first class? Please advise.

The *73* Booth

We had the premiere issue of *Radio Fun* available and got completely cleaned out of the over 3,000 copies we brought. We announced this new publication aimed at newcomers to the hobby in the April *73* and have been getting an average of 100 subscriptions a day ever since. We had 'em lined up at the booth to subscribe.

We had another line of customers signing up for *73* subscriptions. Many were furious at *CQ* for putting *Ham Radio* out of business and then, despite promises to change, continuing as a contest magazine. We sold more *73* subs this year than we've ever sold in the 30 years I've been exhibiting.

I was delighted, too, by the parade of well-wishers who said they enjoy my editorials and agree with them. That's a change from the past, where many claimed they enjoyed 'em, but didn't always agree with me. And I don't think *I've* changed!

A gratifying number of readers stopped to thank me for getting them to (a) stop smoking, (b) take off weight, and (c) go into business and have fun making money.

The *73* crew was even more excited to hear from one advertiser after another about how happy they are with the sales their ads are providing. I'm used to hearing that we outsell *CQ*, but it's been a while since we've outsold *QST* consistently. We've got to watch out or *73* might start getting fat again, like it was a few years ago.

We did make sure that potential *Radio Fun* advertisers got a sample copy of the premiere issue. Many said they wished they'd been in it and wanted to be sure not to miss out when we go monthly starting in September. Since newcomers are responsible for a high percentage of ham sales, this makes sense.

The Ham of the Year!

Johnny Johnston W3BE, our liaison at the FCC, was awarded the coveted Hamvention award this year. An excellent choice. Johnny had some good news for us . . and some bad. On the bright side of the ledger was the success of the no-code license. This has definitely increased our input of new hams. Indeed, many stopped by the *73* booth to thank me for pushing for the no-code license for the last 32 years.

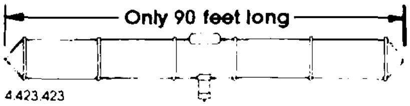
CONTINUOUS COVERAGE ANTENNAS FOR COMMERCIAL & AMATEUR SERVICE

Model AC 3.5-30

$198.00 SHIPPING & HANDLING ADD $4.00

- SWR less than 2:1 from 3.5 to 30 MHz
- Complete assembled Balun terminated with standard SO-239 connector
- Power capability 1 KW - 2 KW PEP ICAS Higher power model is available on special order
- Designed for 50 ohm feedline
- Weather proof balun and balancing network

NEW ACS 3.5-30 WITH #14 STRANDED STAINLESS STEEL WIRE $273.00 SHIPPING & HANDLING ADD $4.00



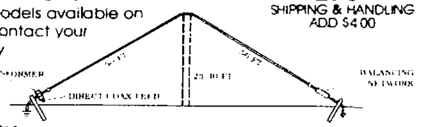
US Patent No 4,423,423

Model AC 1.8-30

$198.00 SHIPPING & HANDLING ADD $4.00

- SWR Max 2:1, 1.4:1 average from 1.8 to 30 MHz
- Can be installed in approximately 80 ft space
- Ideal for commercial services for multi frequency operation without the need for antenna tuners or additional antennas
- Handles 1 KW, 2 KW PEP ICAS
- Higher power models available on special order. Contact your dealer or factory

NEW ACS 1.8-30 WITH #14 STRANDED STAINLESS STEEL WIRE $273.00 SHIPPING & HANDLING ADD $4.00



U.S. Patent No 4,511,898

Continued from page 71

Talk about "never say die"! They also subscribed to *Radio Fun*.

The idea of *Radio Fun*, in case you've just emerged from hibernation, is to make sure that as high a percentage as possible of new licensees actually get on the air and start having fun. It'll be explaining how to get involved with packet, satellites, DXing, contests, certificate hunting, UHF, repeaters, transmitter hunting, ATV and so on. It'll also be running technical articles aimed at helping newcomers understand what this radio stuff is all about. And it'll be reviewing every kit we can get our hands on. Carole Perry WB2MGP has a column for the newcomer. Gordon West WB6NOA shows you how to upgrade.

We also brought along a big stack of the CDs my three record companies have been producing. . . and sold right out. I was pleased to find so many *CD Review* readers stopping by to say hello and keep up the good work. We will.

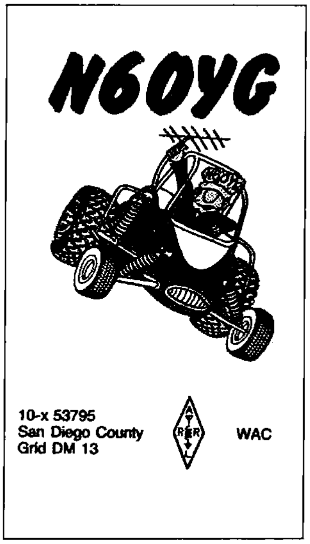
The excitement over the new nocoders was mitigated by Johnny Johnston's mentioning that around 20,000 amateurs have historically been lost each year through winning their Silent Key Award or lack of interest. The 10-year licenses have obscured this loss, giving the deceptive appearance that we've been gaining in numbers. Indeed, at that rate our supposed 500,000 total licensees could eventually be as much as 200,000 overstated. This is what W5YI has been telling us in his newsletter. . . and what the ARRL has been determined to ignore with their inflated numbers. The sorry fact seems to be that even with the new no-code licensing spree, we're only growing at about 1.2% per year. . . one-tenth the growth we averaged in the 1945–1964 era. . . before Incentive Licensing hit.

I was heartened by a parade of readers stopping by the booth to tell me about their successes in getting youngsters into the hobby. I said the same thing to all of them. . . send me some pictures. Prove it. I saw a few more youngsters at the Hamvention this year than previously, but they were still a rare sight. . . nothing like 30 years ago, when kids were all over the place.

You know, I hear all this baloney about how many hams are interested in the code, yet even at the largest hamfest in the world (outside of Japan), there wasn't a code speed contest. They used to be a big feature at virtually every hamfest. I'll tell you what, I'll have *73* print some certificates if your club will put on contests at your hamfests. Let's start making it a matter of pride to be good at copying code. You'll probably want certificates for 20, 30, 40, 50 and 60 wpm. Think that'll hold you?

You say you want practice tapes? Give me a break! Get a computer and do it that way and get off my back.

During my talk, I did mention how easy it is to learn the code at any speed you want. The ensuing rush wiped us out of our 20 wpm tapes at the booth. We also sold out of our $99 videos on how to generate an extra million in sales with PR. We're still getting raves on that. It's even being used by some M.B.A. schools.



QSL of the Month To enter your QSL, mail it in an envelope to *73*, WGE Center, Forest Road, Hancock, NH 03449. Attn: QSL of the Month. Winners receive a one-year Subscription (or extension) to *73*. Entries not in envelopes cannot be accepted.

It was fun, too, meeting so many old friends. Walt WA6BMG, who I used to talk with in 1938 in Brooklyn, where he was W2LBF, was there. Arne SM5AM, who showed me around Stockholm and Aland (OHØ) back in 1966, was there and looking healthy. Norm W2JUP, who took over the RTTY column in *CQ* when I became the editor, was helping AEA show their new stuff. I've been promised an article on their new gear, which is amazing. Friends from South Africa, Kenya, and all over Europe were there and said hello. Jack Aviv WA2KNC, my first *73* employee (1961), was there.

Maybe you'll want to think about joining one of the convoys heading to Dayton next year.

Radio Fun

The subscriptions to *Radio Fun* have been pouring in. That's pretty good considering that it was just announced.

The concept has caught on. The idea of stressing the fun of amateur radio as a follow-on for the new no-code license is timely. We do have a fantastic hobby, one that can be enormous fun. Often we get all involved in some kind of aggravation and forget that fun is what amateur radio is all about. . . the passion which makes it so exciting.

No one is paying us to do this. We're not only spending great gobs of our time on our hobby, but we're spending our own money for the equipment. We provide public service only partly in repayment for the incredibly valuable frequencies we get to use. Mostly we do public service because we enjoy it. It gives us a sense of having done something positive. It gives us a sense of our own value and importance. It gives us an opportunity to do something worthwhile for the common good. It helps give us a feeling that we've contributed to the world. . . and that feels good. . . it's fun.

Somehow, the harder we work at something personal like this, the more fun we have. I treasure the hundreds of times I stayed up most of the night building equipment. But not only did I have a ball doing it, I also laid the foundation for a lifetime of ham publishing.

In 1946 I built one of the first FM modulators into my Meissner Signal Shifter and helped W2GDG pioneer narrowband FM. And I loved every minute of it.

I built all kinds of elaborate RTTY equipment and had so much fun that I had no choice but to start a magazine on the subject to try and inveigle others into sharing the fun I was having. I love to share my enjoyment with others. That's one of the reasons I have so much fun with *CD Review*, my music magazine. I'm getting tens of thousands of people introduced to classical music, to ragtime, and other kinds of music they might otherwise miss.

Okay, goody-goody for me, but how about you? What's the most fun you've had in amateur radio? And why don't you sit down and write about it so we can pass along your story to the *Radio Fun* readers? Have you mixed hamming with sports car rallies? With hot air ballooning? With travel? Why the heck not? I don't see any anchor tied to your ankle. I've done all those things and I can promise you you'll never forget the fun you'll have.

How about building ham gear and test equipment from kits? I've built so many Heathkits I've stopped counting. Old-timers will remember Eico kits. Our Incentive Licensing disaster killed Eico. There are plenty of kits around today that are fun to build. . . and more are coming. With the enthusiasm we can build via *Radio Fun* I'll bet we can get hundreds more parts kits on the market. If you've built a kit you think others would enjoy, let's hear from you! Share your fun the way I do.

How about some ideas on hidden transmitter hunts? Our young newcomers will have a great time if we can get them involved with those. It won't be a bad idea to shake some of the rust off old-timers too. Some of you old coots are about as active as the Tin Man after a rainstorm.

Say, coots, when you find a youngster who is a likely ham prospect, you could spring the $10 for a subscription to *Radio Fun*, right? It's bad enough being an old curmudgeon without being a cheap old curmudgeon to boot.

The Premiere Issue

The first issue of *Radio Fun* is out. We somehow managed to get it out in time for Dayton. I was very impressed with the advertising support we got, sight unseen. I expect you to subscribe and buy at least one piece of gear from each advertiser. Fair is fair, right? That's the least you can do.

We'll be starting the regular monthly publication in September. That'll give you some time to send in articles aimed at making amateur radio more fun—particularly for newcomers. It'll give the ham industry some time to get horsed around to advertising so we can have a big fat publication, packed with kit reviews, simple electronic and radio theory to help you understand what's in those black boxes you've been talking into. You do want to understand how electrons work, don't you?

I expect we'll be seeing some of Editor Bill WB8ELK Brown's fascinating stuff. He came into the office today with a tiny TV transmitter. The darned thing, sent in by KC6CCC, was about 1.5" square and had an exciter on 434 MHz, plus a 100 milliwatt amplifier and modulator, all run by a tiny 9V flashlight battery. He'll no doubt be sending it up with a miniature camera in one of his balloons. Ever tried that? The balloons can get up to 100,000 feet and be copied up to 400 miles away! You just put your TV antenna on your cable converter and tune to channel 60. Voila!

Only $10? How Is That Possible These Days?

Radio Fun is a no-frills publication. We're doing it in a tabloid format, like your local shopper. We want to get information out to help newcomers. . . to make hamming more fun for everyone. This is a labor of love by the *73* staff. We haven't added any extra people. As soon as you add staff and use slick paper, the cost skyrockets and then we have to charge $20 a year just to break even. We'll keep *Radio Fun* at $10 as long as we can, but if it gets too fat we'll have to add some editors and up the subscription price.

Remember too, your $10 is subsidizing 20,000 copies of *Radio Fun* which are going to newcomers to help them get started in our hobby. This is our opportunity to start them off right and help them avoid some of the miseries we went through at first. It's difficult for old-timers to remember how dumb they were at first. . . and how much they needed help.

I think *Radio Fun* may get old-timers to think in terms of elmering youngsters and perhaps even getting down on the Novice bands to lend a hand. . . after turning off their linears. We'll see.

Meanwhile we need all the support we can get. . . in the way of subscriptions, advertising, and enthusiastic articles on exciting ham activities and kit evaluations. 73

Notes from FN42

Of much interest in this month's column is an informative report from Tim Chen BV2A of Taiwan. In conjunction with that, I am including portions of a recent article from The Wall Street Journal, *reporting that Taiwan has ended its civil war with mainland China and recognizes the Beijing leadership.*

"OSL to Box 88, Moscow." How many of you have ever wondered what Box 88 is really like? Now you will find out, thanks to Ron Gang 4X1MK.

Onward to the good news!—Arnie, N1BAC.

ROUNDUP

Switzerland From a message by the ITU Secretary-General, Pekka Tarjanne, about the 1991 World Telecommunication Day which occurred on May 17, 1991:

This year, the theme of World Communication Day is a subject close to the hearts of every one of us: Ensuring the safety of human life. Due to the contributions in this area made by telecommunications, the latter was celebrated as part of the Natural Disaster Prevention Decade proclaimed by the United Nations General Assembly.

The first commercial radio telegraph services were introduced at the end of the 19th century. This new communications medium was a godsend to mariners in distress. Yet, if lives were to be saved, the message had to be heard. For this reason, an international agreement, signed in Berlin in 1906, specified that "Wireless telegraph stations must give absolute priority to receiving and replying to distress signals from ships and take all appropriate action." This same agreement included the international adoption of the SOS signal. The International Telecommunication Union introduced other safety measures: Ships should have a radio set on board and special radio frequencies were reserved for distress signals.

Over the coming decade, the Global Maritime Distress and Safety System will be brought into use. This new system, developed by the International Maritime Organization in collaboration with the ITU and other bodies, will provide a new degree of safety to seafarers.

Transportable satellite earth stations can be used for emergency communications and, coupled with land-based facilities, provide a vital tool for relief operations. However, much remains to be done to ensure the fast transborder movement of such telecommunications equipment to disaster sites. With this in mind, the ITU, working with other concerned organizations, has proposed a project to facilitate the speedy movement and customs clearance of telecommunications equipment for disaster use, which could, in due course, lead to an international convention. Also, cellular technology can prove to be a solution to the difficult problem of providing telecommunications outside major urban areas.

It is, indeed, my ambition to speed up the arrival of relief to anyone in danger, wherever disasters may strike or, more generally, in need of assistance in rural and remote areas.

ISRAEL

D.N. Hanagev 85530
Israel
PACKET: 4X1MK@4Z4SV.ISR.EU

We were greatly relieved with the cessation of the hostilities in the Gulf. It spelled for us here in 4X-land the end of destruction and injury caused, not to mention the disruption of normal life for the month and a half of Operation Desert Storm. The Civil Defense Authorities gave the O.K. to put the gas masks away and open up the rooms (and some hamshacks as well!) that each household had hermetically sealed. Nightlife in the big cities has commenced once again.

The Ministry of Communications issued a special letter of thanks to the Israel Amateur Radio Club in recognition of the public service provided by the amateur community during the crises. Hopefully now diplomacy will take precedence, and we will be able to see the end of the lack of peace accords in the region. The time is ripe, and judging by the trends in the world, that we have noted in this column over the past years, it appears that we are nearing a new age where enlightenment will banish the darkness. Let us all do our part in our own small way, and see to it that our international contacts via ham radio will contribute to the good will!

A Visit to Box 88, Moscow. Early last March, Dr. Oded Schremer 4X4SO was invited to the Soviet Union for a scientific conference. Before leaving for Moscow, Oded got on the air and contacted a few Russian hams, who invited him to visit the Central Radio Club. Upon arriving, Oded saw that his schedule gave him the mornings off. One morning, after calling a number given him for the club, he set off for a visit, accompanied by his interpreter. The club was located an hour and a half from the center of Moscow.

The State-run and supported Central Radio Club is housed in a two-story building somewhat resembling a school. A few rooms house the world famous P.O. Box 88 Moscow QSL bureau, whose six full-time employees sort many, many millions of QSL cards each year! Another room holds a large ham station which normally has a full-time operator who, unfortunately, wasn't there that day.

There is yet another section, full of test equipment and staff to help out those building or repairing their own gear. It should be pointed out that due to economics, imported commercial gear is not available in the USSR, thus almost all stations are homemade.

On the first floor there is an exhibition of all kinds of radio equipment, and the halls of the building are decorated with color posters of sports people and radio amateurs. All in all, the Central Radio Club of Moscow is a building buzzing with activity from early in the morning to late at night.

Nocolai UA3AF, who heads up the operation, showed Oded a beautiful full-color magazine that they put out. Oded told them that he was really thrilled to be inside "Box 88 Moscow," that address being world famous, known to virtually every radio amateur on the globe. This really made the people on hand very proud, as it turns out that they are seldom ever visited by hams from outside of the USSR, and had no idea of their image abroad.

Photo A. Oded Schremer 4X4SO with QSL sorters at "Box 88 Moscow"—the Central Radio Club.

Indeed, the hams at the Central Radio Club had never met anyone from Israel before, and 4X4SO's visit was a big event! Until April 1988 (just 3 short years ago) hams in the Soviet Union were prohibited to contact Israel. They told Oded that this ban had caused them much grief, as they had heard us on the air, and had always wanted to make contact. Life in the USSR has changed since then, with new openness and freedom of expression. Oded parted with his hosts at Box 88 after taking photographs as a souvenir of this historic meeting, having been most warmly received.

Looking out of the car window, as any keen-eyed ham should, Oded spotted a number of beams and quads on the rooftops, but unfortunately did not have the time to visit any hams in their homes. Now, for 4X4SO, Post Office Box 88 Moscow means much more that just an address for QSLs. Hams visiting Moscow would do well if they paid a visit to the Central Radio Club there.

NEW ZEALAND

Des Chapman ZL2VR
459 Kennedy Road
Napier
New Zealand

Hello to all! Just a quick note to advise you that the NZART Hastings Branch, ZL2BEI, is organizing another 160m event to encourage hams to "Have a Go" on 160 meters, and maybe meet new fellow hams who are 160 enthusiasts.

The frequency is 1850 kHz, ±10 kHz, LSB or CW, 0800 to 1200 UTC, 21–22 June 1991. There will be as many ZL stations available as possible.

You may remember that the Hastings Branch ran one of these events last year in October. It generated so much interest that this one has been put together, and we hope that this news reaches you in time to participate.

If the interest continues, the Hastings Branch of the NZART will organize another weekend event for next March in 1992. 73, Des ZL2VR.

The European CEPT License

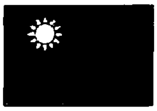
Some years ago, 26 European Telecommunication Authorities agreed upon simplifying the procedures for radio amateur operators to use their ham equipment while visiting CEPT member countries. The result is that no visi-

tor license has to be applied for. You only bring your home country license that states which class of CEPT license you have. There are two classes, Class 1 with both HF and VHF privileges, and Class 2 for VHF (no code required). Last year five East European countries indicated that they will apply for membership in the CEPT community.

So far, 17 CEPT countries have implemented the recommendation for the so-called CEPT license, recommendation T/R 61-01. These countries are: Austria, Belgium, Denmark, Finland, France, Germany, Greece, Italy, Liechtenstein, Luxembourg, Monaco, The Netherlands, Norway, Spain, Sweden, Switzerland, and the United Kingdom.

The identification for using the CEPT license is somewhat cumbersome. Visiting Sweden, a CEPT ham MUST identify as follows: SM/home call/P for portable or /M for mobile. Either /P or /M MUST ALWAYS follow the call. In most countries, it is not necessary to include the number for the call area.

Hams from other countries must, however, apply for a regular visitor license. In the past, Sweden has required a written statement by the local police of the applicant's "good conduct" to be included with the application for a visitor's license. This requirement was deleted on January 1, 1991.



TAIWAN
REPUBLIC OF CHINA

Tim Chen BV2A
PO Box 30-547
Taipei
Republic of China

Although I have not reported in this column for a considerable length of time, I believe that our recent developments in Taiwan may be of much interest.

We have made great strides in amateur radio activities. Local government has given the public the qualification examinations three times: in 1984, 1988, and 1990. As of this date there are more than 300 licensed stations and about 620 ham operators scattered on this island. The majority of the stations are in the second district, BV2, which belongs to Taipei City and Taipei County, with BV4 and BV7 next, and only a few stations located in other districts—BV1, BV3, BV5, BV6, and BV8. BV9 is for offshore islands, and BVØ is reserved for special occasions and DXpeditions. The indications are that the number of amateur radio candidates is increasing rapidly. The best guess is that 2,000 people will participate in the next examination, which hopefully will take place in June 1991.

It will be quite a burden to the authorities to handle this sudden surge in the ham population. They will probably have to revise the rules and administrative matters, as well as develop an examination pool.

Presently there are a great number of young men and women (CBers) who are enthusiastically, though illegally, using V/UHF operations each day on 144 and 430 MHz. The chaos on the air is terrible. How to lead them a dance [control the situation] is a government problem all hams are concerned about.

In spite of the adverse circumstances, hams had an experimental test with Japan last July with VHF and UHF QSOs at three different positions on mountains at 600, 2,000, and 3,200 feet above sea level. The CBers were well-convinced of amateur radio communications being worthwhile. We hope that more and more CBers will change their status and become good hams.

The booming situation makes it necessary for us to set up an independent society strictly of, by, and for the radio amateurs. It will not only assist local hams to further progress, but also foster the good relationship with all the amateur fraternities in the world. We assure that the increase of BV stations will be easy to access on the air in the future. The general assembly of the independent society, temporarily named the Chinese Taipei Amateur Radio League, was scheduled to have its inaugural ceremony on March 10, 1991. Very soon it will apply for membership in the International Amateur Radio Union (IARU).

At this moment there is no change in the regulation that we do not grant licenses to individual visitors. A DXpedition group is usually welcomed and given a special callsign, but the group has to submit an application at least two months in advance for approval. The Post and Telecommunications Department, M.O.C. No. 2 Chang Sha Street, Taipei, Taiwan, ROC is the authority. And if we can be of any service to you, please contact the Chinese Taipei Amateur Radio League (CTARL) at 3F, No. 19, Lane 312, Pa Te Road, 2nd Section, Taipei, R.O.C., or P.O. Box 93, Taipei, Tel. (02) 711-4652, FAX (02) 771-2378. 73, Tim Chen BV2A.

From *The Wall Street Journal*, dateline Taipei, May 1, 1991: After more than 60 years, China's civil war has officially ended, at least in Taiwan's eyes. Taiwan President Lee Teng-hui declared the termination of a period of emergency rule imposed just before the communists took control of China in the late 1940s. The emergency froze in place a state of war with the communists that, despite some periods of cooperation, extended back to the late 1920s. Until now, the Kuomintang government in Taipei officially viewed the Beijing government as rebels who had usurped the KMT's rightful authority to rule mainland China.

President Lee's proclamation, which came as a quasi-official Taiwan delegation visited Beijing for the first wide-ranging talks ever held with mainland officials, represents another important step in the gradual relaxation of tensions across the Taiwan straits.

Hamsats

Continued from page 54

The Soviet Connection

A verified two-way exchange of callsigns was made between Ken KB5AWP and Musa Manarov U2MIR. While mobile-to-mobile contacts are common, space-mobile to space-mobile ham contacts have only begun recently. Ken on *Atlantis* and Musa on *Mir*, the Soviet space station, were the first. The low orbits of the two vehicles make *Mir*/shuttle line-of-sight possibilities uncommon, but for this mission it worked. This time voice was used, but packet could be tried on another flight.

Educational Activities

One of the most successful aspects of SAREX on STS-37 was the communications with educational institutions. The astronauts answered questions from children in many schools. Often the shuttle was not over an area at the correct time for school hours. This necessitated the use of phone links and bridges to hams with direct access to the shuttle at specific times.

In Australia, Graham Ratcliff VK5AGR provided links while Junior de Castro PY2BJO took over from Brazil. The links and phone bridges worked for STS-35, and did the job again for STS-37.

The school connections during April 6 included 10 educational groups from Texas, Ohio, Illinois, California, Pennsylvania, and Oklahoma. Many others listened to the two-way conversations through the link system created by the SAREX supporters. SAREX brought the space program into many classrooms in several countries during the flight.

SAREX In the Future

Enormous effort has been required to make SAREX a reality. Hundreds of hams have been involved with parts of the program. Organizers and promoters like Bill Tynan W3XO and Roy Neal K6DUE have put in long hours to find the support needed to make SAREX happen. Roy has announced that new video tapes documenting the program will be available when school starts this fall. Lou McFadin W5DID is perhaps the key ham responsible for flight gear. Several hundred documents and drawings have been required by NASA before allowing the ham equipment in the shuttle. Lou and his group fulfilled the requirements.

It is hoped that all the effort to operate SAREX on four flights will now begin to pay off. Rather than being classed as an additional experiment each time, SAREX gear could be available for use by any ham/astronaut requesting the system for a specific mission.

The next opportunity for SAREX may be later this year or early in 1992. One astronaut has expressed an interest, and others may be joining the ranks of amateur radio very soon. An intensive weekend ham radio course is in the planning stage for a group of current and future astronauts. While STS-35 stressed packet communications and STS-37 promoted educational efforts, a more "standard" ham-QSO activity is expected for the next chance. An all-ham crew may be a first this time, but it may be quite common in a few years.

HAM HELP

Your Bulletin Board

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full (8½" x 11") sheet of paper. You may also upload a listing as E-mail to Sysop to the 73 BBS /Hamhelp SIG. (2400 baud, 8 data bits, no parity, 1 stop bit. (603) 525-4438). Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters 1 or i, or even the number 7. Thank you for your cooperation.

I would like to hear from hams that operated club station KJ6DO on Johnson Island. History, information, QSL card, or pictures would greatly be appreciated. *Chuck Bowers KJ6DO, 837 Ridgeview Ct., Oakdale CA 95361.*

WANTED: Compact disk to learn and improve speed of CW. *Doug Franklin VE3EYE, #77 Glasgow St., Conestogo, Ontario, Canada NØB 1NØ.*

I urgently need schematics and manual for a Santec ST-142 handie-talkie, to repair mine by the time my license arrives. Will pay for copies. Thanks. *Jeno F. Racz, 850 September Drive, Cupertino CA 95014.*

I am looking for software and connection into (such as Galfo) to operate an Apple IIc with an MFJ-1224 CW/RTTY interface. *Bruce Danielson WA1WOG, 4 King James Drive, East Lyme CT 06333.*

I need a copy of the schematics or booklets on the SBE 33, the Hallicrafters SX-101, and HT-34. If you know of any upgrades or improvements to these items, I would appreciate it. *Paul Christie ex-K2UKT, 208-27-15th Rd., Bayside NY 11360.*

I need a schematic for a METSAT, model 1500 computer-based weather satellite video scan converter, and connections to Tandy CoCo 64. Will pay for copying and mailing. *William A. Rizzo, P.O. Box 578, Pago Pago, Am. Samoa 96799.*

I am fourteen-years-old, and have just started working towards my Novice ticket. I would like to thank all the staff at *73* for the great articles that gave me the inspiration to get my license.

I have a problem with getting radio equipment, though, and would like to ask all the hams out there if they have any extra stuff just collecting dust that could get me started towards my Extra license. I would also like to ask any ham in the Modesto, California, area if they have any interest in helping me get my Novice license. I'm having trouble with the code. *Brandon Wilson, 920 Briggs Ave., Modesto CA 95351.*

Need instruction manual or copy for Drake MN-2000 antenna tuner. Need overall chassis schematic and service manual for Tempo/Uniden 2020 transceiver. Willing to pay copy and postage costs. *Evan Rolek K9SQG, 2053 Mohave Dr., Dayton OH 45431. (513) 426-1986.*

HAMS WITH CLASS

Carole Perry WB2MGP
P O. Box 131646
Staten Island NY 10313-0006

An Uplifting Experience

"Now, class, for today's lesson we're going to discuss how to QSL to our terrestrial QSO with the astroham, and plan our unit on SAREX and the STS-37 mission in reference to the deployment of the Gamma Ray Observatory." Who would ever have believed a few years ago that this could ever be an authentic opening statement for a teacher to make to a 6th grade class, or that the youngsters would understand and respond eagerly to it?

Of all the exciting adventures that teaching amateur radio in a classroom has led me to, none excites me as much as our involvement with the space program. The remarkable thing about this topic is that it is so dynamic. Intrinsic in the material are new and creative ways to introduce space studies to children.

Therefore, I jumped at the chance to accept an invitation by the Johnson Space Center Amateur Radio Club to participate at the SAREX Booth of the National High School Science Teachers Convention in Houston, Texas, this past March. I knew that I'd enjoy talking about amateur radio in the classroom at the convention, I just had no idea how momentous a trip this would turn out to be.

Rosalie White WA1STO, head of the ARRL Education Department, and I had a wonderful time at the booth with our hosts John WD5EEV and Karen Nickel WD5EEU, Dale Martin KG5U, and Ruth Ann Barret KB5MOT. Hundreds of science teachers stopped by the booth to learn more about SAREX (Shuttle Amateur Radio EXperiment) and how it can be used to motivate youngsters in a classroom.

During my visit to the Johnson Space Center, I was privileged to address the amateur radio club there and share some of my classroom experiences with them.

The highlight of the whole week came when John took us to the WETF (Weightless Environment Training Facility) at the space center to meet with mission specialist Jay Apt N5QWL. Jay had made a contact with my kids on the CQ All Schools Net last October, so you might think I wouldn't be unduly overwhelmed at the prospect of meeting with him in person. You'd be wrong. I was absolutely awestruck by what I got to see and do that morning. Jay was warm and gracious and even invited me onto the diving platform for a picture to show the children. He'll never know what an impact those photos had in my school. Children with all different backgrounds and abilities were enchanted with the album I put on display. They identified with my experiences, and related to the feeling of pride for the astronauts' work, that I conveyed to them.

As I watched Jay being submerged into the pool to practice new spacewalk equipment and techniques, I thought about what phenomenal courage and dedication it takes to be an astronaut. Too many of us have become jaded about space shuttle travel, and we tend to take for granted the very special people who help make it seem easy.

At this point, pilot Ken Cameron KB5AWP joined us at the WETF. He too was gracious enough to spend time and respond to questions that I knew the children would love to have me ask. He gave me an autographed photo of the STS-37 crew which is presently displayed in the showcase of our school's lobby.

The upcoming launch of the *Atlantis* on April 5 was starting to take on a very personal meaning to me. Personal contact with these extraordinary people either in person or on a radio has to heighten interest even in the most blasé of children. That's why one of the goals of SAREX is to encourage public participation in the space program; another is to support educational opportunities offered by amateur radio voice and digital communications.

Photo B. Astronaut Jay Apt N5QWL welcomes Carole Perry WB2MGP on board the diving platform at the WETF

Photo C. Carole with Atlantis *pilot Ken Cameron KB5AWP.*

Photo D. A view from the press site of the Kennedy Space Center. Notice the countdown clock.

Photo A. Carole Perry WB2MGP and John Nickel WD5EEV have fun working W5RRR at the Johnson Space Center.

Because all five of the astronauts on STS-37 are hams, and because of my meeting two of them in person, I decided to accept an invitation by *73 Magazine* to see the launch of the *Atlantis* at the Kennedy Space Center in Florida.

I took the opportunity to attend various press briefings before the launch. Reporters were given the chance to ask in-depth questions of experts involved with the development of the Gamma Ray Observatory from TRW, and to attend conferences about SAREX, biomedical research, and structural information relating to the mission.

Lift-Off!

There aren't many events I consider worth getting up at 4 a.m. to attend, but the lift-off of the *Atlantis* surpassed my wildest expectations. Dawn broke as I

approached the Kennedy Space Center that morning—along with a downpour of rain. There was cloud cover all morning, and it was touch and go up until the planned pause with nine minutes left in the countdown. Launch officials switched runway-approach directions for *Atlantis* in the event it had to make an emergency landing at Kennedy Space Center. The shuttle's three main engines and two booster rockets ignited at 9:22 a.m.—four minutes behind schedule. With a fiery leap off launch pad 39B, *Atlantis* zoomed through the low cloud cover and soared eastward over the Atlantic Ocean.

Mesmerized, I watched this phenomenal event from the base of the countdown clock at the press site. When I heard the announcement, "We have lift-off of the *Atlantis*," I felt an unparalled surge of pride. As the *Atlantis* disappeared into the clouds, I turned around to see that same "special look" on the faces of the other reporters. Some were teary-eyed, some were applauding and cheering, but everyone was smiling.

In the quiet moments of walking back to my car in the parking lot, I tried to sort out the euphoric feelings and the incredible myriad of stimuli of the last week. The only thing I could think of as I drove out of the space center was that this was one spring break when the *teacher* would have the best "Show and Tell" of anyone in the class. 73

Space Travel and Communications

The National Air and Space Museum, in collaboration with NASA, has prepared a wonderful book for teachers, called *Discovery*. The following are some ideas for classroom activities, all of which can be adapted to suit your age and ability group.

1. Have students interview an older adult, such as a grandparent, and ask about Neil Armstrong's first steps on the moon on July 20, 1969. Students might ask the adult: "Where were you?" "How did you feel?" Have students tape their interview so it can be shared with the class.

2. Discuss why some astronauts need to wear spacesuits. Have one student trace around another student's body while he or she lies flat on a large piece of paper. Have students design a spacesuit on the tracing, labeling all the different parts of the suit. Remind students not to forget any important items. Then have them color the suit and add their nametags.

3. The *Saturn V* rocket was used to launch the *Apollo* spacecraft. As an art lesson, have the students build small models of the *Saturn V* launch vehicle. Use cardboard tubes for the body, a cone-shaped paper cup for the nose, light cardboard for fins, and pieces of plastic drinking straws for the engines. The students may write a story or play about launching their rockets and what it carried (payload) or helped to launch.

4. One *Skylab* crew spent Christmas in *Skylab*. Form student groups and let them choose a holiday and plan a celebration for a *Skylab* crew. Remind them to think of the small area, limited storage, and weightlessness.

For more information about what resources are available for classroom teachers, contact: The Education Resource Center, Office of Education P-700, National Air and Space Museum, Smithsonian Institution, Washington, D.C. 20560. Tel. (202) 786-2109.

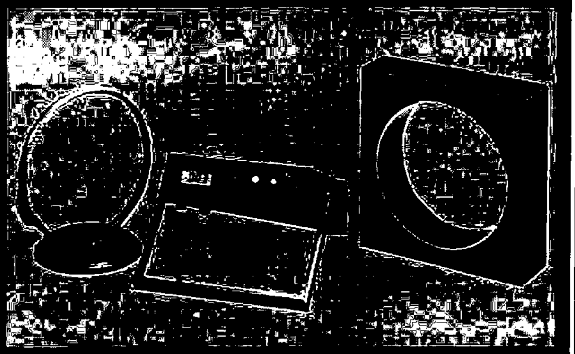
AC & DC ELECTROMAGNETIC FIELD RADIATION MEASUREMENT



Portable Fluxmeter for broad range field measurements

SENSITIVITY — From gamma range (1 gamma = 0.00001 gauss) to 199.9kGauss — Earth's field typically 0.5 gauss. Sensitivity determined by pick-up coil.
FREQUENCY — DC to 100kHz
FEATURES — Fully portable — battery or line powered • Analog output • Low cost • One year warranty

TYPICAL APPLICATIONS
• ELF field measurement of power lines, transformers, motors, lamp ballasts, etc.
• CRT / VDT field measurement
• Clean room environment analysis
• Determine magnetic shielding effectiveness

The Last of the HW-9!

I was checking my electronic mail from CompuServe one night and there it was, a note saying Heathkit will be dropping the HW-9. The good *do* die young. I have no idea how many HW-9s have been sold, but they were a very popular QRP radio. After logging off CompuServe, I got somewhat misty-eyed and brought down my little green HW-8. Ah, yes! This is QRP if ever there was.

After finding the power cord and a suitable length of coax with an RCA plug on the end, it was QRP time on 40 meters. But something was wrong. For the life of me, I could not make a single contact with anyone. Off went the cables, and the HW-8 took a trip to the repair bench.

With Heath gear, I always like to go through and check out the alignment. Any trouble areas will easily pop out. In my case, several trouble areas came right up to the surface.

The first problem was with the VFO. It was way off frequency. Heath has a strange way of calibrating the HW-8 that is both time-consuming and hit or miss. Heath wants you to zero beat the output of the VFO to a receiver tuned to 7.0 MHz or 7.250 MHz. You end up moving two VFOs—the HW-8 VFO and the receiver's VFO. This is a real pooper! There's a better way to do it.

Tuning the HW-8

You'll need a frequency counter and some patience. The VFO generates frequencies from 8.645 MHz to 8.895 MHz. A good place to tap the VFO is on the emitter of Q3, the emitter follower, of the VFO. From here you'll be able to see the exact frequency the VFO is running at. Then it's time to play cat and mouse. The VFO must be adjusted to operate properly. Follow the instructions in the manual.

Basically, you move the VFO to one end of the band, adjust trimmer capacitor C302B (the screw adjust on the main VFO capacitor), and move the VFO to the upper end and adjust L9. You keep going back and forth until the zero on the dial and the 250 mark fall exactly on 7.000 MHz and 7.250 MHz, with the band switch in the 7.0 MHz position, of course. With a frequency counter connected to Q3, the values will be 8.645 MHz and 8.895 MHz.

It's easier said than done. No matter how I tried, I could not get the VFO to track 100 percent. The slug in L9 would not turn smoothly enough. It snapped back and forth. I ended up with the high end of the band out of alignment just a tad.

My reasoning is that most of the activity for the HW-8 is on the CW bands, and that that is where the VFO should be most accurate. It works for me.

When working on the HW-8's VFO, be sure to allow ample time, so the VFO can warm up to operating temperature. Use a stable power supply, not dead batteries. After I got the VFO back in line, the second problem came up to bite me: no VFO transmit offset.

When the HW-8 goes to transmit, diode D11 effectively adds capacitor C55 to the VFO, which causes a downward shift to the VFO frequency. This should produce a fixed offset of 750 Hz during transmit. In my HW-8, C55 did in fact get switched into the VFO. Only trouble was, the offset was 3 kHz, not the desired 750 Hz. Useful, but hardly interchangeable. The offender was C55. It changed value. The fix was simple: Replace C55 with a good capacitor. But I went one step further. I tried adding a small value trimmer capacitor in place of C55.

Experiment, Experiment

My thinking was simple: adjust the trimmer capacitor to the offset I wanted. But it didn't work! The trimmer changed the alignment of the VFO. The trimmer was not stable enough to use on the air. All in all, a pooper and a half. Heath's value of 6 pF is a good value to stay with. I ended up using 5 pF and having a 730 Hz offset. Capacitor C55 is kind of hard to get at. I removed the old one and soldered the new one on the trace side of the PC board. Bent down on the board, the capacitor fits quite nicely.

To see how much offset you have during transmit, connect your counter up to the emitter of transistor Q5. Here you'll see the exact operating frequency of the HW-8. During transmit, C55 shifts the transmitter down. You'll see this shift at this test point. As a thought, here would be a good place to add a buffer/amplifier for a digital readout, replacing the analog dial in the HW-8. I can see it now. An LCD display instead of the plastic dial used now.

When I brought out the HW-8, I had to dig up the 2000 ohm headphones required. I found them in a dark corner of the basement. After 15 minutes of use, I remembered why they were in a dark corner of the basement. With this thought, how about some modifications for the HW-8?

The most common mod for the HW-8 is the addition of a small grain-of-wheat bulb behind the meter. It makes a super "on" indicator. Use a small terminal strip to hold the bulb in place. Tap +12 volts from the power switch and use the chassis for negative return. Simple, but really first class.

Building an S-Meter for the HW-8

This modification is simple and easy to build. With easy to come by parts, we can have an S-meter for the HW-8. Granted it's not the best S-meter in the world, but it's an S-meter nonetheless. The circuit consists of nothing more

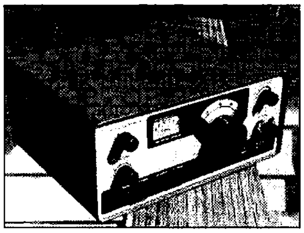

Photo A. The green QRP box, the HW-8, is a solid performer even on today's band.

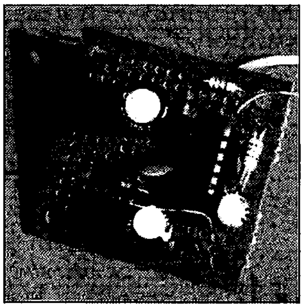

Photo B. The 2 watt audio amplifier assembled on perfboard.

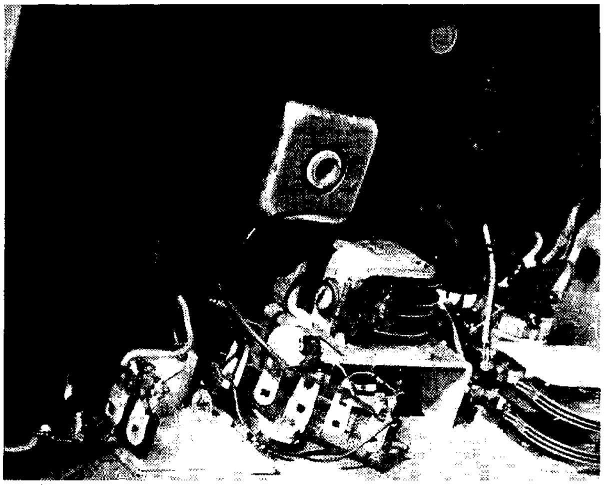

Photo C. Terminal strip holding the S-meter parts. The grain-of-wheat bulb is barely noticeable behind the meter's face.

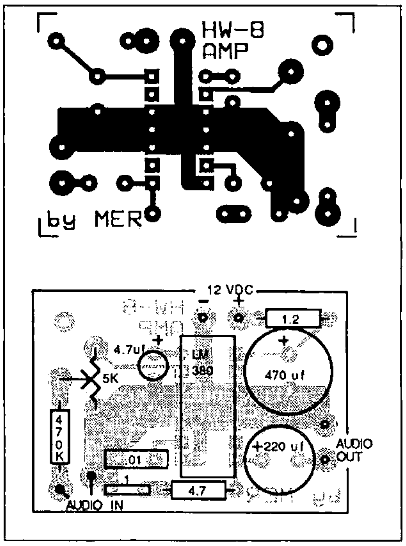

Figure 3. (a) PC board foil pattern for the audio amplifier. (b) Parts placement.

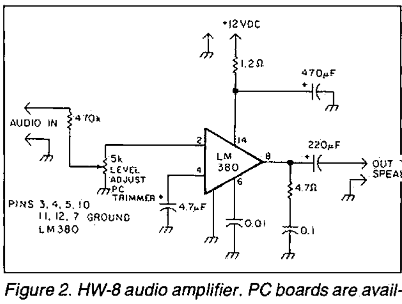

Figure 2. HW-8 audio amplifier. PC boards are available for $3 + $1.50 postage from Far Circuits, 18N640 Field Court, Dundee IL 60118.

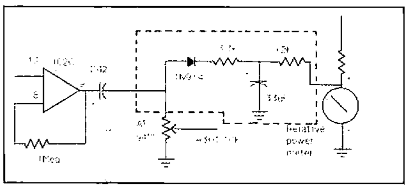

Figure 1. An S-meter for the HW-8.

than two resistors, a diode, and a capacitor.

Here's how it works. We steal a small amount of audio from the volume control at the junction of C42 and the pot. The diode rectifies the audio while the 33 µF capacitor smooths out the signal. The DC level is then connected to the plus side of the meter via the 12k resistor.

You may want to change this value to suit your needs. I found the 12k value to work well for me. This S-meter does not in any way affect the operation of the meter during transmit. The louder the signal, the more the meter moves. No one is really S-9, but the meter can be used to center the VFO to the audio filter by tuning for maximum reading. Besides that, it is great to watch the meter do something when the HW-8 is receiving.

Wanting a simple method for driving a speaker is nothing new for the HW-8. Here is my version based on the LM380, a 2 watt audio chip. This chip has lower internally generated noise than the popular LM386. The chip is widely used for audio power amplifiers in Ten-Tec radios. Here is my version, simple and easy to get running. Not much need to explain how it works. Audio from the headphone jack is routed to the amplifier board. A 5k trimmer adjusts the level going into the board. I wanted to be able to operate both the internal power amplifier and the headphones, whenever desired.

I adjusted the trimmer to supply a good level to the headphone jack and the internal amplifier. A small circuit board was used. One-hole mounting or a piece of double-sided tape works well, too, with the board mounted close to the headphone jack.

The power plug on the HW-8 has six conductors, of which only two are used for power. Here I took advantage of the extra pins and routed the power from the HW-8 to the audio amplifier via the power plug.

The power switch is external to the HW-8, and is in fact part of the power plug. The audio to the speaker is also routed to the last two pins—no need to drill holes in the HW-8 this way. By making up two different power plugs, you can run with headphones-only in the woods, then return home and plug into the internal audio amplifier and external speaker.

After these simple modifications, the HW-8 was back to its former self, banging out QSOs one after another. So what does this all lead to, you ask? Well, don't you know, there are many more modifications for the HW-7, HW-8, and the HW-9 in the HW-8 *Handbook.* Get your copy from me for $7.95 plus $1.00 postage at the address above.

What's in store for next month? Beats me. I'm heading out to the local K-Mart with my camera. Heard on the scanner that Elvis was seen there working in the shoe department. What a country! 73

Both models in 10M, 6M, 2M, 1-1/4M, 70cm
100W.....Power Handling.....165W
20dB.....Gain.....25dB
less than 0.6dB...Noise...less than 0.6dB
$117.00.....Retail.....$165.00

For many years MIRAGE/klm has provided Amateurs throughout the world with the best equipment for their communications needs.

Whether you've needed an H-F tribander to chase DX or crossed YAGIs to bounce around the corner or around the world . . . we've answered the CQ.

When you asked for more UHF/VHF power in an amplifier and higher accuracy in a wattmeter, MIRAGE/klm came through.

We will continue our long-standing pledge to quality and performance into the 90's.

Knobs, Buttons and Switches

No matter what kind of gear you're running, one thing is sure: It is controlled through switches and/or knobs of some kind. Even computers, with their inherent software approach, gel down to human business via buttons, mice, keyboards, or some other mechanical arrangement. Until practical voice input control comes along or touch screens become popular, knobs and switches will continue to be the way to go.

Given their mechanical nature, it is not surprising that switches and controls are frequent sources of trouble. Many times, a "serious" problem will turn out to be nothing more than a dirty control or a flaky switch. Let's look at how and why these things happen and how to find and fix them.

On Again, Off Again

Simple on/off switches, which do no more than make and break circuits, come in a variety of styles. Each type is subject to its own peculiar failure modes.

Toggle switches, similar to the normal "light switch" style, rely on contact pressure for connection. The actual contact is usually on the side of the switch opposite the handle's pointing direction, because the handle is pivoted at its midpoint. The pressure, applied by a spring in the handle, is usually considerable.

The most common causes of failure of toggle switches are contact corrosion and bending of the contacting element. I've seen both. Corrosion is nearly always caused by excessive current through the switch, especially if it is applied while the switch is being turned on or off. (And after all, that is the point of a switch, right?) The effect is a "blackening" of the contact points and a poor or nonexistent connection, no matter how much pressure is applied.

An extreme example of this phenomenon occurs in really heavy-current applications like HF linear amplifiers. If the switch is turned on precisely when the AC current phase coming from the wall happens to be at its peak, the inrush current can be enormous, and the switch can actually weld itself permanently closed! My MLA-2500 amp has done this several times. Once it happens, the only way to shut it off is to unplug it!

Even then, the switch remains firmly welded "on," although this particular one can be pried apart with a screwdriver because its innards happen to be accessible. The best cure is a new switch, but it, too, can be welded in short order. When replacing a welded switch, always use the highest-rated one you can get, and make sure that it is rated for more current than the one you're replacing. On my amp, I've taken to using an outboard switch on a heavy-duty power strip.

Another cause of corrosion, more common in slide switches but also seen in toggles, is the drying out of the original lubricant. I don't know the name of this stuff, but there is a grease-type substance applied to many switches' contacts (especially those of Japanese origin), and it dries out over a period of five or more years. When dry, it resembles a hard black tar, and it is *not* conductive.

Assuming you can get the switch open, the obvious temptation here is to scrape the contacts clean. Beware: Many switch contacts, especially the high-current-capacity type, are plated. Scraping usually will remove the plating along with the problem. The switch may work fine, but it won't work for long. Without the plating, it will quickly corrode and go bad. If you *must* scrape, do it as carefully as you can, with fine sandpaper.

Another approach is to dab on a small amount of a powerful tarnish remover, such as Tarn-X™. This stuff is basically diluted acid, and it will clean those contacts to like-new status. It may also eat through the plating and the nonmetallic switch components, so be sure to wash your work off with plenty of water after a minute or so of the tarnish remover. Also, read and follow all the warnings printed on the bottle; this is not stuff you want to be careless with.

Slide on Over

Probably the most troublesome type of switch is the slide switch. These beasties are used for many things, including transmit/receive switching and band switching. They are chosen for these jobs because they can easily be made to have many poles which all switch at once, but they are much smaller than rotary switches. A big slide switch may have six or even 10 or more poles, each one a double-throw, yet be small enough to fit into a miniature radio.

The prevalent failure mode in slide switches is corrosion. Although their connections depend on the pressure of tiny fingers sliding along a long bar, the contact pressure really isn't strong enough to keep things clean through the resulting scraping motion. The fingers seem to keep their springiness for many years, but the bars get quite ugly. The primary cause seems to be that darned lubricant again. Also, simple oxidation and, of course, cigarette smoke residue take their toll. If you have an intermittent band switch, check its connections to the board first. If they are OK, the likely cause is contact corrosion.

Radio Shack and others sell sprays which are supposed to degrease and clean switch contacts. My success with them has been marginal at best. Sometimes they can help in a switch which has just started to malfunction, but usually they have no lasting effect. And I have yet to find a spray which will dissolve that black hard lubricant tar.

So, what's to do? Far and away, the easiest and best solution is to get another switch! It may look like a big hassle to replace a six-inch-long band switch with 30 contacts but, believe me, it is easier than the emergency method I am about to describe.

Ready, Doctor?

OK, you've got a bad band switch and you either can't get another one (you mean they don't still stock parts for that Yamasutsi 1972 special??) or you don't want to wait through the long ordering process. I ran into just such a case with a Panasonic shortwave receiver made in 1978. It was a nice little radio, but the band switch had gone bad, resulting in its not doing much of anything at all. Spraying did no good, so I decided to take the plunge and do surgery on the switch. Be warned: This is not for the faint of heart nor squinty of eyesight. Here's how to do it.

The first order of business is to remove the switch from the rig. Get some desoldering wick and carefully disconnect the offender, contact by contact. Usually, the metal body of the switch will be soldered at its corners to ground traces on the board, and you'll have to unsolder those, too. Once you have the switch out of the rig, the fun begins.

The bottom of the switch will probably be made out of a plastic or phenolic material similar to that used to make printed circuit boards. Extending around it at the edges will be metal tabs protruding from the metal top shell. Very carefully, bend the tabs back just enough so that you can remove the casing. Don't bend them all the way—it isn't necessary and greatly increases the risk of their breaking off. Now, gently pull the shell away from the bottom. Be prepared for some of the internal switch fingers to fall out. They are quite small, and if you lose one, you have ruined the switch! Keep a cup or other container handy to store them. Also, if the slider is spring-loaded, uncontrolled release can result in switch parts all over the room! Go slow.

Most of the fingers probably will still be on the center rods. Gently pull them off and put them away. The objects of your attention are the flat center rods around which the fingers were clasped. Most likely, the rod surface will be brown or black. This is the stuff you want to remove. Probably the best method is the tarnish remover. Clean everything up, wet it down and let it dry completely before proceeding. While the piece is drying, take a look at the switch fingers you removed. They should look OK but if they don't, try wetting a piece of paper with some spray contact cleaner (*not* tarnish remover) and sliding it between the fingers. Be very careful not to bend them apart. Then, let them dry, too.

When you're ready to reassemble the switch, replace the fingers on the center rods. Look at the slider and you will see the indentations where the fingers belong. You must position the fingers on the rods such that they will line up with these indentations. Don't try putting the fingers into the indentations and then pressing the whole thing onto the rod; you will bend or break the fingers. If there's a slider spring, put it in place now. Line up the shell and gently try to push the phenolic into it. If it resists, one of the fingers probably is not lined up correctly. Never force the assembly or you'll break it. Reseat the finger and try again. This is the most difficult part of the operation.

Once you've got it back together (and you're sure it's right), press the shell's securing tabs back over the phenolic and you're all set. The switch should be good as new! As you can tell from the description, this procedure is risky and hardly worth the effort unless you have no choice. But I've used it a number of times and saved some nice gear.

Around and Around

Rotary switches are basically round slide switches, and they suffer similar failures. They present some unique problems, though, because their construction can make access difficult. If you can get to the problem, which is almost certainly corrosion, try some cleaning spray. If that won't do it, dab on the tarnish remover. Unfortunately, you usually can't wash the switch off properly afterward, because it is still in the rig! Dab as much water on as you can and pat it off with a paper towel. Needless to say, let it all dry *completely* before turning on the power! I don't recommend disassembling rotaries, or even trying to remove them from the rig, especially if they are of the multi-level type, which most are. It's just too difficult, and the chances of getting it all back together again without causing other damage are small.

Push My Buttons

Push-buttons come in many forms, from the old-fashioned round long-travel type to the modern membrane variety. Some push-buttons are really slide switches in disguise. A quick peek behind the front panel will tell you for sure. The old long-travel types are so plentiful that it just doesn't pay to try to fix them. Besides, I've never had much luck with fixing one; the switch always wound up working, but not reliably.

Membrane switches, as used on modern HTs and HF rigs, are very reliable. The usual cause of failure is from having something (typically soda) spilled into them. If you can, order a new keypad. if not, you can often pull them apart by peeling the adhesive layers from each other. A good cleaning with some tape head cleaner will usually restore these pads to normal. Just be sure to line the two halves up properly before you press them back together.

See the Light

Optical encoders, used for tuning today's microprocessor-controlled HF rigs, are not mechanical switches at all. They employ a pair of LEDs and photodiodes in an interrupter arrangement. As you spin the dial, a slotted plate alternately passes and interrupts the light to the photodiodes. Each blip of light represents some fraction of a turn. The direction of the rotation is determined through a clever scheme: The light paths are arranged so that one changes state while the other is halfway through its position. Rotating the dial clockwise will cause one photodiode to detect a change before the other, while rotating counterclockwise will reverse the order. It is a simple matter to decode the changing states into direction and speed information. By the way, most computer mice use this arrangement.

The usual cause of failure in optical encoders is electronic, rather than mechanical. Either an LED or photodiode goes bad, or the associated decoding circuitry fails. In either event, new parts are called for.

Well, there are several other kinds of switches, including microswitches and relays. Also, there are potentiometers, and they are among the most troublesome of all components. We'll continue this exploration next month. 73

Shuttle ATV Success!

During the STS-37 mission last April some record breaking contacts were made via 70 cm ATV. Six selected stations in all made the attempt to uplink live video to the orbiting shuttle during several passes over the U.S.

Considering that the shuttle was using a window-mounted antenna and the distances that needed to be covered (at times over 1500 miles), the uplink sites had to mount a massive effort to generate the most ERP (Effective Radiated Power) possible. The individual stations generally ran 400 watts or more. Some of the sites also used multiple antennas (or a 40-foot dish, in the case of the Goddard U.S. Naval Academy site—see the photo of this dish in the May "QRX" column). The stations making the attempt were Jim Steffen KC6A in Long Beach, California; the Johnson Space Center ARC W5RRR in Houston, Texas; Andy Bachler N9AB with the Motorola ARC in Schaumburg, Illinois; the Marshall Space Flight Center ARC WA4NZD in Huntsville, Alabama; Goddard Space Center ARC WA3NAN in Greenbelt, Maryland (the Goddard group also uplinked via the U.S. Naval Academy dish in Annapolis, Maryland) and Kai Siwiak KE4PT representing the Motorola club in Ft. Lauderdale, Florida.

The first scheduled attempt was unsuccessful due to the position of the orbiter. However, orbit 32 was a different story! Jim Steffen KC6A started out the pass with great reception by the *Atlantis* even when it was far out over the Pacific Ocean. Jim was running a K2RIW amplifier running 600 watts into a single KLM-18C. Next, the Marshall group WA4NZD sent some excellent video up to the shuttle showing the club members who helped set up their station (see the June "QRX" section for a picture of the group and their antenna system).

Andy N9AB next sent up a video tape of the liftoff of the *Atlantis*. This marked the first time any shuttle crew has been able to view their liftoff while still in orbit! Andy was one of the furthest stations away from the orbiter due to his northern location near Chicago (elevation angles of only a few degrees). He ran a kilowatt into a 16-bay array of quagis to make up the difference.

Due to the success of this scheduled uplink, the next morning another opportunity was made available. The crew on board *Atlantis* first received a taped uplink from N9AB of a local school's shuttle mission simulation (the Millburn School in Wadsworth, Illinois). Next the Goddard/U.S. Naval Academy group was able to send up a nearly snow-free COLOR signal. Of course, the Henry amplifier and the 40 foot dish may have helped a little! At the end of the tape recorded on board the shuttle, a very weak image of a SAREX patch could be discerned. This was sent by Kai Siwiak KE4PT in Ft. Lauderdale, Florida. The Johnson Space Center ARC W5RRR video effort was not seen on the shuttle's videotapes (although it may well be viewable upon further analysis). The JSC effort was undertaken by T. Brad Smith KA5CDJ and others in the club.

Thanks to the efforts of Gerry Creager N5JXS, we can show you still frames of the actual videotape as received on STS-37. Gerry printed Photos A–D out on a SONY UP500B videoprinter. While they may seem rather snowy at first glance, keep in mind that the actual video appears clearer since the eye tends to average out some noise.

How It All Began

After the SSTV experiments on STS-51F by Tony England W0ORE, fast-scan TV seemed the next logical step. Back in early 1987, Andy Bachler N9AB discussed the idea with Lou McFadin W5DID and decided that the experiment would be feasible. The Motorola ARC (Illinois chapter) put together a proposal (building on a previous proposal by Art Anzic K8BVI from the NASA Lewis Center) and Andy submitted it in May of that year.

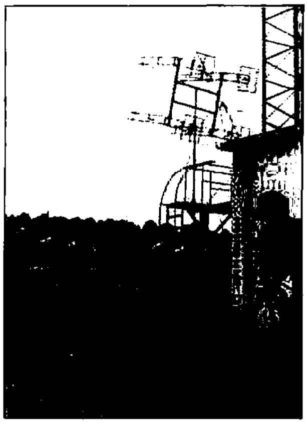
While the FSTV project was underway, a need for a new side-window-mounted shuttle antenna for the STS-35 mission arose. A dual-band antenna which allowed simultaneous 2 meter operation and 70 cm FSTV receive was designed and built by Jim Phillips and Andy Bachler N9AB at Motorola in Schaumburg, Illinois.

Photo A. Jim Steffen KC6A as received by the shuttle Atlantis

Photo B. The Marshall Amateur Radio Club sends their best to the shuttle.

Photo C. N9AB reception by the shuttle. Eighth grade student Chelsea Papangian (Millburn School in Wadsworth, Illinois) makes her debut as simulated mission commander.

Photo D. A nearly snow-free signal in full color was received from the Goddard/US Naval Academy effort WA3NAN.



Bill Bily WB9DIG built the prototype shuttle ATV downconverter using parts of a Motorola HT and TV IF circuitry suggested by Tom O'Hara W6ORG. With the aid of Fred Reimers N9ETW (also known as FAR Circuits), the downconverter was built on a custom PC board to produce a very compact package which integrated nicely with the rest of the SAREX equipment.

Future Possibilities

Enhancements to the shuttle's receive system and ground station capabilities should result in even better performance in future missions. A lot has been learned by this experiment, and it's hoped that it can be flown again in the near future.

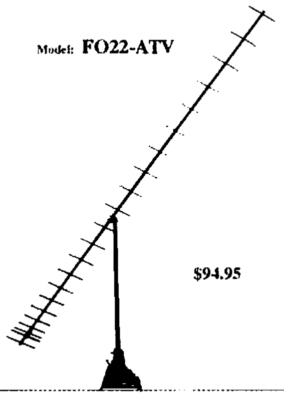
RUTLAND ARRAYS
ANNOUNCES
THE HIGHEST GAIN ATV ANTENNA YOU CAN BUY!
Model: FO22-ATV

MEASURED GAIN >15.8 dBd



ELECTRICAL SPECIFICATIONS:
Gain bandwidth .... 420-450 MHz
VSWR < 1.33:1 415 to 450 MHz
E-Plane beamwidth .... 23 Deg.
H-Plane beamwidth .... 24 Deg
Sidelobe attenuation
1st E-Plane .... -17.5 dB
1st H-Plane .... -15.5 dB
Maximum power .... 1500 Watts
F/B ratio .... 22 dB
Impedance .... 50 ohm

MECHANICAL SPECIFICATIONS:
Length .... 14 Ft
Boom .... 1" OD 6061 T-6 Al
Elements .... 3/16" Al rod
Mast .... up to 1.5" dia.
Wind surface area .... .78 Sq.Ft.
Wind survival .... 90+ MPH
All Stainless Steel Element Hardware
Coax connector .... N-type
Polarization: Horizontal or Vertical

ALSO AVAILABLE
RA4-50, RA7-50, RA8-2UWB, FO12-144, FO12-147, FO15-144

Fastnet Rock Lighthouse

Look for a unique expedition this July from the Fastnet Rock Lighthouse just off of the southern coast of Ireland. As one of Europe's most westerly and loneliest outposts, the lighthouse has been an important gateway for transatlantic shipping since 1854. Since the "Rock" is lashed by the full force of Atlantic gales (even during the summer), a boat landing is possible only 12 times a year. The group plans to ferry all radio equipment and supplies over by helicopter on July 9 and continue operations for 10 days.

The expedition will operate under the callsign EJ7FRL (Fastnet Rock Lighthouse) on the following frequencies: SSB—3.775, 7.075, 14.140, 14.240, 21.275, 28.450 and 144.260 MHz. CW—3.510, 7.010, 14.010, 14.030, 21.010, 21.030, 28.010, 28.030 and 144.040 MHz. Also look for the group on 160m and the WARC bands. The IOTA (Islands On The Air) reference number is EU-121. QSL via EI2BB. *[Thanks to EI3GU for the above information.]*

More DX Techniques

No doubt you heeded my suggestions made in last month's article, and listened very carefully to each DX station before calling. Remember, I said *listen, listen, listen!*

Yes, listening is the name of the game, then putting your signal where the DX station is listening. You must understand what the operator is going to do next, how the operator is working stations, and where the operator is listening. Otherwise you will be playing DX roulette, and you will probably spend many frustrating, even fruitless, hours calling, calling, and calling, but never working the DX station.

If the DX station is working stations in split mode (he is working stations above or below his own transmit frequency), you should find the stations he is working, and note whether these stations are on the same frequency, or higher or lower, each time.

An experienced DX operator with a reasonable pile-up will work stations progressively higher (or lower) in frequency each time until he reaches the limit of his "listening window," which may be 5 to 10 kHz wide, or even wider. When he reaches the limit of the window, a DX operator will usually move back to the beginning of the window and start moving up (or down) in frequency again. A rare DX station will usually have a large to gigantic pile-up to work, and may be listening over a much larger window, up to 50 kHz wide. The wider the window, the more difficult it is for us to work the DX station.

It is very helpful if you can monitor both the DX station and the pile-up simultaneously. Some modern transceivers offer this capability, otherwise you must use an extra receiver. You can drive one earphone from one receiver and one from the other receiver.

As soon as the DX station signs over to a station, start searching the pile-up to locate the lucky operator. But don't be fooled by the odd operators who send "599" or "59" and are not actually working your DX station. There are always a few in every pile-up who insist on confusing matters by sending bogus reports. There may also be other QSOs taking place within the window, or more than one pile-up taking place in the same area of the band.

Second Guessing

Okay, so you have found the stations he is working. If you are lucky, you can transmit on or near that frequency and work him. But it is better to listen to several contacts and determine just how far he moves his receiver each time, and whether he is working more than one station on each frequency before moving on. You are trying to guess what he will do next.

When you have determined his pattern, you are ready to put your callsign on the correct frequency and hopefully work him within a reasonable period of time.

One suggestion—if you are calling, but haven't worked him within a reasonable period of time, say 15 to 20 minutes—either you may not have figured out his pattern, or you have, but too many other DXers also have. Another possibility is that propagation is not favoring your area. Take a break. Come back to the pile-up in 15 to 20 minutes with a new attitude—listen, learn his pattern, and get him!

If you have been unable to figure out his pattern, you may sit on one frequency and call each time he says "over" or "QRZ." This is a poor technique, but sometimes it works. Though this is an unsophisticated technique, it is especially effective if you have a commanding signal and are on a relatively clear frequency. I have worked several DXpeditions this way when I could not figure out the pattern, but knew they were tuning through a window of frequencies.

It is also a useful technique to use for a DX station who insists on spreading their pile-ups over a large window or who use a channel technique where the operator listens only on spot frequencies (channels) located every 10 kHz or so. This so-called channel technique can be extremely difficult for calling stations, and usually spreads the pile-up over a large portion of the band, since most of the calling operators don't know the channel technique is being used.

Pile-up Don'ts

There is also a long list of pile-up don'ts.

Don't make long calls; keep your calling sequence short and sweet, especially if the DX station is working stations very quickly.

Don't transmit on the DX station's frequency if he is working split. No matter what you say, someone will almost always respond, often in an unkind or insulting manner.

Don't respond to jamming or insults.

Don't transmit when the DX station is transmitting.

Don't transmit when the DX station requests a particular callsign fragment ("W5K," "last letter echo," "Europe only," etc.) unless, of course, the request matches your callsign or geographical location.

Don't mention your name, QTH, etc., unless the DX station requests such information.

Next month we'll discuss some techniques for special situations and go over some DXing how-to books.

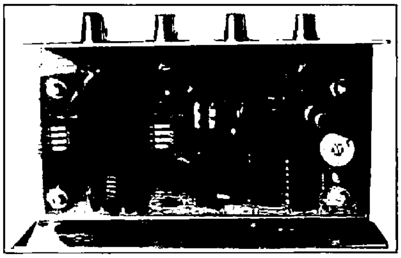
UPDATES

June Photo Switcheroo

As we were all on our way to the Dayton Hamvention, the gremlins decided to have a little fun with two of our articles. In the June issue, Photo A on page 10 and Photo A on page 34 somehow got mixed up. To correct this, we offer a cut-and-paste solution! Since the photos are the same size, just cut out the attached photos and paste them in the correct article. If you don't want to cut up your magazine, just photocopy them.



In the June Issue, the top photo should be placed over Photo A on page 34. The bottom photo should be placed over Photo A on page 10.

Michigan Scanner Law

See the May "QRX." John Evanish N8LBD writes: "In your 'QRX' in the May '91 issue on scanner law, you said [Michigan] law exempts licensed amateurs except for Novices and Technicians. This is incorrect."

According to a copy of H.B. No. 4750, Sec. 508, which John N8LBD sent with his letter, Technician Class operators are also exempt.

Odds and Ends

I met several hundred of you at Dayton this year. Thanks for all the kind words about the magazine and this column.

—— • ——

Radio Fun is succeeding beyond even Wayne's wildest dreams (and Wayne has some pretty wild dreams!). The premier issue sold out in about three weeks, though your local ham store may have a few copies left. Subscription orders are coming in by the bagful every day. Look for the start of monthly publication with the September issue.

—— • ——

Despite the fact that our advertisers are reporting incredible sales from their ads in *73*, there are several companies that remain conspicuous by their absence from these pages. Companies like Ten Tec, Cushcraft, Radio Shack, Kantronics, Standard, Ham Radio Outlet, Henry Radio and Optoelectronics continue to ignore the fact that advertising in *73* will make money for them.

Some of the advertisers who *do* take out space in *73* will take out two or three times the space in *QST* or *CQ*. Why? I've always maintained that *73* readers spend more money than readers of other ham magazines. Many of our advertisers have recently reported this to be exactly the case. If you, patient reader, want to see a fatter *73*, it's up to you to make sure every amateur radio advertiser knows that you read *73*. That means that when you call a company for information, tell them you saw their ad in *73*. When you order a piece of gear, tell the person on the phone or behind the counter that you saw the ad in *73*. If a company is not advertising in *73*, write or call them and tell them you're interested in their product, but since they don't advertise in *73* you have no idea what they offer. It's no mystery. . . ad pages pay for editorial pages on a roughly 50/50 basis. When we have more ad pages, you get more great reviews, construction projects and all the other stuff you want. Give the above named companies a call—and any others you come across—and ask them why they're throwing away perfectly good money by not advertising in *73*. Then call me and let me know what they tell you.

—— • ——

I have a source at the FCC in Washington who informs me that there are several countries who are preparing WARC 92 proposals that would take away the entire 40 meter band. No, I'm not kidding. My source also informs me that many countries around the world are making recordings of American hams on 14.313 and the phone portion of 80 meters. They are planning to submit these recordings into the official proceedings at WARC 92 to support their proposals asking for the re-allocation of HF amateur frequencies to other services. Remember, every country gets only one vote at WARC. That means that when it comes down to the final tally, we have the same power as any small African, South American, Asian or Middle Eastern country (and these smaller nations desperately want our HF spectrum). While we Americans exercise our First Amendment right of free speech on the HF bands, we all ought to remember that other countries do not enjoy nor understand such a permissive right. With the right to speak freely comes the responsibility to use that right wisely. Think about it.

—— • ——

Donna DiRusso, the *73* Advertising Accounts Services Rep for the past three years, has been transferred over to one of Wayne's other magazines (*CD Review*). Donna has been the person who makes sure our advertisers are happy and she has done an outstanding job. We will all miss her very much. Sue Colbert is taking Donna's place at Ad Account Services. She is already cracking the whip and letting Dan and Louise (the *73* ad sales dynamic duo) know who's boss. Welcome to The Team, Sue.

—— • ——

My wife and I just bought our first house, so it looks like you're all stuck with me for at least the next 30 years (unless you want to help pay off some of the mortgage). It's a traditional Cape, nestled among the trees (but not too many trees), perched on top of a hill on three-and-a-half acres. The lot is a ham's dream. Oddly enough, a good radio sight was not one of the things we were looking for. It just happened that way. Really!

—— • ——

There's a group of hams down in Houston who are doing a great job of promoting amateur radio. They're called the Houston Amateur Radio Helpline and they've got some very nice PR pieces. If you want to see what can be done with a little imagination and very little money, drop 'em a line at 16410 Havenhurst, Houston TX 77059-5307. Their phone number is (713) 488-4HAM. Congratulations to the Houston area hams. We need more like you.

—— • ——

I was reading in one of the amateur radio news bulletins (I forget which one) about an organized effort by some packet radio groups to get the FCC to fire the guy who wrote the citations for passing commercial traffic on packet (remember. . . the 900-line message that circulated during Operation Desert Storm). Will someone please tell these people to knock it off. The last thing we need is to be causing the FCC more headaches with this kind of petty crap. The guy was just doing his job. He may have had some personal motive behind his actions, but I haven't seen any proof. The fines have been cancelled anyway, so what's the big deal? This gentleman did us a favor by showing how vulnerable our packet system is. So, instead of doing the typical stupid ham thing of screaming and yelling for this guy to lose his job (give me a break!), why don't we learn from this experience and either clean up our act or get a rule change?

—— • ——

As reported widely last month, there's a ham in Ohio who is in a whole kettle of hot water for interfering with police and other emergency communications. This guy apparently had a pretty sophisticated setup, with taped sirens for background noise and thousands of dollars of modified radio gear. His favorite game was to make a false "officer in distress" call, then watch the "fun" as a whole police department went into a panic trying to find an injured police officer who didn't exist. The thing that burns me about this whole story is the fact that this guy is a high school teacher and advisor to the high school radio club! Unbelievable! I hope this guy gets the psychiatric help he so obviously needs. I also hope that, if found guilty, he rots in a jail cell for a very long time.

—— • ——

Why is it that amateur radio manufacturers often advertise great looking new gear several months before it is available? I can understand advertising a bit in advance to generate interest, but some of our better known companies are taking this to ridiculous extremes.

—— • ——

I spend a lot of time on the air. If you ever hear me, don't hesitate to break in and say "Hi." If I'm home (and not mowing the three-and-a-half acres) on weekends, look for me on 40, 17 or the Novice or FM portions of 10. I usually check 28.365 MHz on the half hour, so try giving me a call. If you're a night owl, you can often catch me gabbing with N1GVA, N1GOJ and NU1W after midnight around 3.915 MHz (Friday or Saturday nights are your best bets). You can also find me on RTTY on 10, 15 and 40. Try the RTTY portion of 15 first. It's my favorite RTTY band. Don't be shy. I'd love to meet you. 73

There's some exciting news this month: a total solar eclipse on July 11. The path of total darkness will cover the Hawaiian Islands and portions of Mexico. A partial eclipse will be viewable in S.W. Canada, the United States, except for the tip of Maine; Mexico and Central America; and South America, except for the Tierra del Fuego area. Then, on July 26, there will be a penumbral eclipse of the moon, which means it will only be in partial, not complete, shadow.

Propagation conditions during July ordinarily exhibit what we call the summer doldrums, since the HF bands for DX are not as lively as they are in spring and fall. Yet some excellent propagation can occur this month, so don't give up! July is typically a vacation month, and lots of hams will be portable or mobile on the HF bands. Expect plenty of short skip, especially on the most-used bands of 15 and 10 meters, but also on 20 and 40. . .and some DX, too.

As this is being prepared (late March, early April), the sun has been showing some remarkable activity. For the past month or six weeks, solar flux has been very high—more than expected—in the 200–300 flux units range. Also, there have been numerous large spot groups on the solar surface facing earth, accompanied by major flare activity. On some days, two and three major flares were recorded, and polar cap disturbances and proton events on earth or near earth have been numerous. Following the flares by two or three days, DX has been especially good on all HF bands, not bad considering Cycle 22 is now on the downswing. However, the spot groups are nearing the solar equator, a sure sign that Cycle 22 is drawing to a close.

Conditions this month ought to be fairly quiet, with fewer flares and magnetic field disturbances on earth. The 8th through 11th, and the 22nd through the 29th, are anticipated to be poorer days for propagation than the remainder of the month. As always, check WWV or the latest forecast at 18 minutes after each hour. Use the band-time-direction chart for planning your best times for DX operaton, and use the daily conditions chart to guide your decisions. Let me know how the eclipses affect propagation in your area. See you next month. 73

LETTERS

From the Hamshack

George Fennell N3EQE, Butler PA A couple of other hams and I have started ATVing in Butler County and are having a ball. P5 audio and video is all around. This is the most fun I've had in ages. I just finished setting in a 10-foot parabolic to do EME and shuttle downlink (to rebroadcast on ATV) and am building a couple of transverters. I also bought a Kenwood 531A 1.2 GHz transceiver, and am building a small 24" parabolic antenna for that. To think that I could be missing all this fun while worrying about upgrading and building code speed. Maybe someday, but definitely not now. We're cooking with microwaves and having a blast. (Must avoid ionization of oneself—did you know that a crack in the waveguide of a 13cm, 1 kW amp 2 1/4" x 1/64" will produce energy 250,000 times the safe [?] exposure limit? WOW—that's what those cramps are!)

You should be starting some stuff for Radio Fun *to help get newcomers interested in ATV, 1200 MHz, and so on. Let's get on the ball and get more hams interested in doing fun things—and perhaps get them off the 20 garbage truck. . . . Wayne*

Ignatius N. Bova WA3GWD, Pittsburgh PA Mr. Jason Kelly's letter *[June '91 issue]* really irritated me. First, I would like to inform him that Morse code was included in the amateur tests for good reason. Our operators could get through under severe QRM using Morse code. Under emergency conditions, where ham operators are counted on to provide critical communications, this is a very valuable asset.

As for the existing amateurs being "a bunch of old men," I can only wonder how he would know. Do ham operators in Iowa give their age as well as their call?

Most ham operators are concerned, and rightly so, that some of the valuable ham bands could turn into another CB fiasco. Back in the 60s, like many ham operators, I read about all the wonderful things CB was going to do for ham radio. CB would "open the door" for many potential ham operators, and this would be the spark that would ignite new interest in this valuable resource. Baloney!

Mr. Kelly, I suggest that you listen in on the CB bands. It would be heart-breaking to have this happen on 2 and 6 meters.

The FCC does not have the resources to control the CB wasteland, and they certainly can't expect more funds with the federal budget bursting at the seams. If we get our bands run over by rude and careless operators, it is doubtful that the FCC could do anything about it, and we would all be the losers because of it.

First, re the code for getting through when conditions are tough. I've heard this claim for 50 years, and as far as I know, there is no authenticated case in the last 30 years of any amateur having to resort to code to get through in an emergency. Yes, of course it's possible it's just incredibly unlikely. With most of today's transceivers not even having a key jack, we may never know.

The old men complaint Kelly makes is echoed dozens of times a month in the mail I'm getting from new hams. It isn't difficult to discover age when you ask a chap what he does and he says he's been retired for 10 years. I finally ran into a non-retired ham last Saturday—first in months.

At a recent hamfest I asked for a show of hands of how many present with General or better licenses would be able to pass a 13 per exam right then. Ten hands went up out of the whole room. A few years ago I proposed as a joke that we all be re-examined for code speed every year. The reaction was one of total panic.

You say "rightfully so" about turning our ham bands into CB. This shows me two things: 1. You haven't listened to 20m for the last year or so. It's worse than any CB I've ever heard. 2. You haven't listened to CB in years.

CB did indeed help us enormously. Until CB came along, we had a negative growth for several years. Almost 100% of our actual growth in the last 20 years has come from people who got started in CB and moved up to hamming.

I'm just back from L.A. I've never heard anything as bad as their 2m repeaters on CB. . . anywhere. And I often take a CB rig with me for use in my rental cars when I travel. I find CBers usually much more helpful than hams if I need to find my way or make a phone call.

Of course, I haven't been to Pittsburgh in years, and you may have a pocket of bad CBers. But remember, only two people in history have been arrested, tried, convicted, and put in prison for bad language on CB. . . and both were Extra Class hams. It's almost enough to make a person think! But maybe not. . . . Wayne

Alan S. Koester NOCALL yet, Coral Springs FL I finally did it! Last night I passed the basic theory tests and became licensed as a no-code Tech. I am anxiously awaiting the arrival of my callsign. Like many others, I felt the code requirement was an obstacle I was not yet ready to overcome. I think that the no-code Tech license is an excellent way to get a taste of amateur radio. From what I have seen and read so far, once the amateur radio bug bites, the effects are permanent. I, too, plan on upgrading to General in the near future. For now, however, my new no-code Tech license will enable me to get started in this great hobby.

My advice for anyone interested in becoming a no-code Tech is to ignore the disgruntled old-timers. We are not "glorified CBers." Good luck to anyone who will be taking the test. Have confidence in yourself. You can do it. I did!

Dorian Blasdell N7PCT, Grants Pass OR In February 1990 I wrote you a letter saying that I couldn't find out where to take the ham radio exams. I believe you printed it in the July 1990 issue.

Here is a progress report. In February 1990 I went to Radio Shack and asked if they knew where the license exams were taking place. They did! I took the Novice, CW, and written exams that month and passed. Then in May 1990 I passed the Technician exam. When December 1990 rolled around, I passed the General and Advanced CW and written exams. Finally in May 1991 I passed the Amateur Extra CW and written exams. I am now 18 years old. Ham radio is lots of fun.

Dorian N7PCT—yes we did print your letter in the July 1990 issue. Thanks for a fine progress report! . . Linda KA1UKM

Ervin L. Sly W6TKJ, Nipomo CA I fully agree with your statements of last month on the crowded 2 meter band. Just moved from the Los Angeles area and my transceiver would scan all day long and not hear a signal. Once in a while I'd hear someone on the way to work or from work, but the rest of the day—nothing. Simplex? Forget it! Find it even worse here. Also on camping trips I can get into many repeaters but there's never anyone listening. Where do they come up with crowded conditions on 2 meters?

Sure enjoy your ranting and raving.

Gerardo O. Lopez Meza XE1UQL, Veracruz, Mexico Radio communications has been the most important activity of my free time. Unfortunately, I found out about it when I was too old to direct my professional advantages over the area. Anyway, I enjoy it deeply, and I understand that every one of us must increase the interest of the people about the many different things you can do in radio.

Three years after I looked for someone to teach me Morse code, I got my license, then I discovered that almost no one uses it regularly; the amateurs prefer voice 10 to 1. The problem—I think—is that some people use the inexpensive ham bands for business, so the government tests the neophyte's interest by means of the code examination.

There are many repeaters and radio amateurs in Mexico and all Spanish America, and they are always happy to answer every QSO received. In Veracruz we love to talk with other persons from far countries.

I want to express to you my desire for people to use more the 10 meter band and to learn to make QSOs in Spanish. You are losing half of America without this language.

Jeffrey Miller KB2FBI, Austin TX Good issue, the June *73*. You waxed quite eloquent this month. It will take several visits to the euphamism *(sic)* to read it all. Nonetheless, right on the mark about standing around watching the foreigners invent everything new and useful, while the useless simply complain about the new Techies. How about a new bumper sticker? You could make hundreds! "I'll give up CW when they pry my cold, dead hands from my brass key!"

Jim Farago, Minneapolis MN Per the June issue, page 76 on "rigs for kids": In your editorial you talk about how various parts from TV sets could be used to make no-cost QRP rigs and such. I have 40 new B/W picture tubes, 9" through 24", 15 good used ones 4" through 21", plus a few hundred TV tubes, replacement TV antennas, line cords, deflection yokes, etc., all of which I would give away to any interested individual, club, or organization. Schematics, too.

I am not looking for a tax write-off or a trash can—I just hope I can give these items to someone interested. Half of these sets are tube-type and half are transistorized. Brands from A to Z. The TV shops I used to work in are all closed now, so they are no help.

I do not want to put these items out with the trash to end up polluting a landfill.

It was good to speak to you at last November's Hamfest at Hennipin Technical Center, even though you were *much* too busy for any lengthy conversation.

Anyone interested in these parts can contact Jim Farago at 4017 42 Ave. So., Minneapolis MN 55406. PLEASE enclose an SASE. . . . Linda KA1UKM

Tom Rehnert N5PLX, Socorro NM Several years ago I got some mail from you hawking your magazine. I was already familiar with it and planning on someday getting a subscription. What struck me about the mail was that it contained a letter from you that was something like 13 pages long. I thought to myself that this guy must have some great large ego to think I'd read all this. It convinced me to get a subscription. I did read it all. I've been getting a big kick out of your editorials ever since. The magazine is the most fun to read and I always look forward to it.

Charles Holm KB7HUW, Spokane WA I am a Novice operator and enjoy your magazine very much. Your new magazine, *Radio Fun*, looks interesting, and I will be subscribing. Its introduction at this time, now that newcomers can get a license without knowing the code, will certainly help the new operators along, as well as inspire technically inclined people to get a license and join us on the air. You were promoting a no-code license years ago, and predicted its adoption. Again, you were right!

Mike Simmons WB9CWE, Belvidere IL Several months ago, you wrote in a *73* editorial about the hazards of low frequency electromagnetic fields as reported in a very reputable magazine. A few months ago, the XYL of an old acquaintance, Ed Pelc (formerly K9RAX), called us. Grief-stricken, she told us that her husband had been undergoing grueling treatments for leukemia, and she greatly feared for his life. The news had a particularly shocking effect, as Mr. Pelc was a TV repairman; he had spent most of his life surrounded by low level EM radiation in his shop.

As a former quality control engineer, I know that one case is poor proof for anything, but it does make one sit up and take serious notice.

James Moe N6ZOB, Newport Beach CA The April *73* described a DXpedition to Malpelo Island (page 81). These remarkable people operated five radios for about five days and logged 40,000 QSOs.

If they managed to keep all five going for 24 hours/day, this works out to about 66 QSOs/hour per radio. This ought to be considered some sort of a record. It must have been especially tough on a 20 wpm CW operator.

This leaves me wondering—is a 60-second QSO what ham radio is all about?

H.S. Van Winckel VE3FWE, Ontario As a Canadian ham, I have been a long-time fan of yours, having followed your career and agreeing with you on the past, present, and future of amateur radio. Here in Canada, I'm one small voice in the mess that we call ham radio, however I voice my opinions as often as I can. Please keep trying, the Amateur Radio Fraternity needs people like you to remind us of the problems we face. 73

NEVER SAY DIE

Wayne Green W2NSD/1

. . . de W2NSD/1

Humph, sked time and you're late, as usual. How'm I going to get you to shape up and stop being a wishy-washy wimp? And don't try and put on that "sensitive" act with me, I know you too well.

What in heck has happened to you? When you were a kid you had a sense of adventure. You were willing to be a pioneer. Some pioneer you are now! You don't even see the new movies before Ebert tells you whether you're going to like 'em or not. Pioneer? Pfagh! No, most of you've turned into milquetoasts.

Here you are with the greatest opportunity to pioneer in the history of the hobby. So what are you doing, endlessly gabbing on 2m through repeaters or blathering and kvetching about the mess KV4FZ and K1MAN have made on the low bands?

Are you even on packet yet? Or RTTY? The Japanese are busy discovering ways to squeeze high definition TV (HDTV) into narrower bandwidths. They've just announced a new digital audio format, the mini-disc (MD), which crams 74 minutes of digital sound on a 2.5" disc.

Old-timers will remember the '20s and '30s when Germany had the edge on high technology. German cameras, radios and scientific instruments were the best. Then they got involved with Hitler and screwed up. Through the '40s to the '60s America was way out ahead in almost every technology. The world bought Hallicrafters radios, Kodak cameras and General Radio instruments.

Then Japan discovered Ed Demming and the odd concept that quality really does count. Now we're all buying Japanese cameras, radios and scientific instruments. We're also, in case you haven't noticed, seeing Japanese pioneers skiing down Mt. Everest, crossing the Antarctic on skis, and inventing circles around us in one scientific field after another.

So here you are in amateur radio, firmly stuck in the past, all emotionally worked up over CW, a sad remnant of the '30s. I'll bet 50% of you aren't aware that CW is every bit as important to us today as preserving other antique modes such as AM and spark. Yes, I know, most of the "Spark Forever" crew have their Silent Key awards now and are grumpily moldering. Well, they gave up with the same grace with which our CW-forever brethren are folding their hands . . . buoyed on by the enthusiastic support of the Antique Radio Relay League. Radio *relay*? Har-de-har. Talk about a monument to the past! And let's not even talk about the hoary old goats you've repeatedly elected to help keep amateur radio an archeological resource.

But is amateur radio supposed to be using the incredibly valuable public airwaves as a monument to the past? Aren't we supposed to be experimenting? To be inventing? To be pioneering? Isn't there something in our charter about that? You bet your sweet bippy there is!

So while hordes of you are trying to resuscitate dying technologies such as AM and CW from the dim past, who have we got out there taking advantage of the technological explosion? Certainly not many here in America.

When I speak at hamfests I get blank stares when I bring up new technologies which have been written about recently in *Newsweek* and *Time*. A recent *Forbes* article put our situation into perspective. Today's technology is heading toward the microwaves, where there are more frequencies . . . the frequencies it's going to take to deal with HDTV, personal communicators which handle fax, messaging, and even graphics, computer networking, etc.

So here we are with 500 MHz up there at 10,000–10,500 MHz, with maybe 10 hams in the country using the band. Maybe less. Even if we use today's technology we can get our voice channels down to 5 kHz, which would give us 100,000 channels. Hey, we could all have our own repeater channels and never have to bother talking with anyone else again!

But, as these channels turn from solid gold to platinum, and the commercial demand escalates, unless we're up there doing something of value with 'em, they're going to go. I realize that this is a matter of little moment to most hams. I just don't understand how we ever got amateur radio off 600 meters and up to 160 meters a few generations ago.

That was back when Americans were pioneers. Back when we were eagerly exploring new technologies. Back when Americans were exploring the world. Back when we had some guts. Old-timers will remember Lowell Thomas, Frank Buck, Osa and Martin Johnson, Amelia Earhart, Frank Hawkes, Admiral Byrd.

Old-time hams will remember Copthorne McDonald (SSTV), W2GDG (NBFM), W2BFD (RTTY), W1FZJ (moonbounce and parametric amplifiers). These chaps didn't invent and pioneer to be good guys and save our hobby; they did it because they were having fun. I knew 'em all well. So what's happened to our country that we've stopped having fun with technology? These days 99.9% of us are appliance jockeys.

No, it isn't age. Sam Harris W1FZJ/KP4 was busy pioneering until the day he died. So was John Williams W2BFD. I think I could make a good case for old Doc Spock being at the bottom of this softening of America.

Yes, of course I have a solution. But it isn't one you're going to like. The solution lies in our youngsters. Perhaps we can sneak into our schools and start countering the general concept that technology is bad. Maybe we can get the kids interested in the fun we have to offer . . . not in rag-chewing endlessly, but in experimenting . . . in pioneering new communications.

The food is there on the table, with fascinating stuff from AEA and other ham maufacturers. The question is, how can we get today's hams, starved as they are for excitement and making up for it by making a shambles of our bands, to reach out and even taste the banquet? Please advise. It's out there, waiting. It isn't expensive, but it does mean having to learn . . . and to *dare*.

220 Lives!

A reader, who's in the communications business, advises that while we American hams may not be doing much with 220, there is a brisk business going on just to our south. The drug business in Colombia is apparently delighted with the 220 band and busy buying portable repeaters, HTs with scramblers in hundred lots, mobile transceivers, $15,000 monitors, amplifiers, antennas, night vision equipment, and so on. Hey, they've got to get that cocaine up here for our crack houses, right?

A good friend who ran a ham store in Boston said he often had Hispanic men come into his store with huge rolls of money wanting to buy 144 and 220 MHz repeaters and HTs for cash. Maybe the ham equipment business isn't as badly off as I thought.

Drug dealers make so much money on each delivery that they can afford to buy a repeater and HTs and throw them away after one use. I wonder where the Colombian surplus stores are. There may be some great buys.

U.S. vs. Japan

In case there's a question in your mind about what our new no-code license can do for us, let's just look and see what's happened in Japan, where they've had such a license for years. The May issue of *CQ Ham Radio*, *QST*'s Japanese equivalent, was the usual 586-page phone-book-sized magazine.

Yes, I've been endlessly hearing that unless we keep out the riffraff, we'll end up with one huge CB mess here in America. Well, for more than 20 years we've kept our barriers up to discourage the unwashed hordes, yet when I listen to 20m I hear worse garbage these days than I've heard on CB in years.

So how have the Japanese fared with their no-code licensing? I think we can get a good indication just by looking at their ham magazines . . . which are all monsters compared to the anemic ham magazines we have left here.

Looking over the May *CQHR*, the first 270 pages are solid advertising, mostly in four colors. The last 64 pages of the book are also advertising . . . plus many ads in between. They not only have all the ham gear we have available here, they also have a whole bunch of wonderful products that aren't being exported to the U.S. because our market is too small to bother.

After the front of the magazine advertising section they have 24 pages of fundamental antenna information—how they work—how to use a dip meter to tune your antenna—measuring antenna impedance—how to build a simple Z-meter—building simple low- and high-pass filters—building a 40 meter curtain—and a dozen or so more simple antennas. Then comes IC fundamentals and 14 pages of easy IC building projects.

There's a simple three transistor 10m FM rig construction article, a 440 MHz 25 watt amplifier and a good article on using DAT recorders with amateur radio. There are reviews of a computer logging program, a JRC 0.1–30 MHz receiver, an Azden 10m FM transceiver, a couple of new HTs, and the Yaesu FT-1011 transceiver.

Next comes basic transistor theory, more antenna articles, more simple construction projects, a colorful new products section, DXpedition pictures (in color), hamshack photos, satellite news, DX awards and certificates. The hamfest and club activity photo section has 163 full-color group photos. There are activity report sections for every

Ham Physicians Speak Up

"Only a person familiar with both medicine and amateur radio can make this determination correctly," writes Christine Haycock, M.D., WB2YBA, in a letter to fellow physicians published in *New Jersey Medicine*. She is referring, of course, to the telegraphy waiver for handicapped hams. In December 1990 the FCC passed Docket 90-356, exempting handicapped persons from code tests if their physical condition prevents them from learning the code at 13 or 20 wpm. Dr. Haycock notes: "Totally handicapped quadriplegics have mastered these requirements, as well as blind or deaf individuals, and the psychological benefits of this achievement are immeasurable. There are, however, some rare instances where an individual cannot meet this goal, hence the FCC edict."

Morris Soled, M.D., W2NXS advises non-ham colleagues that "Ham radio is a popular hobby among physicians, and you should be able to find a member of your staff to answer further questions before being a 'nice guy' and signing a note you do not understand."

Dr. Edward N. Ludin, M.D., K2UK, president of the Medical Amateur Radio Council, Ltd., MARCO, was also published. He notes that the precise meaning of "severely handicapped individual" is unclear in relation to the Act *[the 1988 Developmental Disabilities Act, 29 USC 706(15)(A)(III)]*, and that the average physician ". . could not be expected to know what effect these disabilities may have on [a person's ability in] learning Morse code." Like Doctors Haycock and Soled, he urges physicians to not sign a certificate of exemption lightly. He says, ". . . please request, from a local amateur operator, preferably another physician, appropriate advice. I hope that other physician hams will let their fellow physicians at the local level know of their availability in this regard." TNX *W5YI Report, Vol. 13, Issue 12.*

A Brave Young Ham

One of the highlights of K6IR's trek to the Dayton Hamvention was meeting Seth XU1SS from Kampuchea. "What a fascinating story of bravery and hardship," K6IR writes us. "Seth's amateur radio operations from the jungles of Kampuchea using the call XU1SS while under enemy gunfire . . . his heroic escape from Kampuchea . . . and his ultimate reunion, after over a decade of separation, with his family in Washington State after the death of his brother . . . all add up to a tale worthy of a suspenseful movie. The enclosed photo of this brave young man *[see Photo A]* who has endured so much belies the tragedies he has endured in his young life. Seth is truly a remarkable young man and an outstanding tribute to our worldwide hobby of amateur radio." TNX Kenneth M. Miller K6IR.

Photo A. Seth XU1SS (left) from Kampuchea and Ken Miller K6IR (right) meet at the Dayton Hamvention.

Mir Wants News!

U5MIR requests packet stations leaving messages on U5MIR-1 to include news—most messages are boring! KP4BJD had the ". . . unique opportunity, the rare pleasure, to QSO in FM voice with cosmonaut Sergey Krikalev U5MIR for about two minutes . . ." last June. He lists four messages from Sergey: 1. He sends to all: Greetings from space! 2. He congratulates the ship crew and NASA for the successful launch of mission STS-40 and the shuttle *Columbia*, and looks forward to making a QSO in FM voice when their footprints overlap. 3. He respectfully requests all the earth packet stations leaving messages on U5MIR to please kindly include news; they need entertainment, and the usual content of the messages they now receive is boring. 4. Sergey will be available on his "free time" for more FM voice QSOs on 145.55 MHz. *Dosvidaniya* to all from space. De KP4BJD @ KP4GE.PR.USA.CARB.

No American Woodpecker

The U.S. Air Force has scrapped its plans for an over-the-horizon backscatter (OTH-B) radar system, according to *Jane's Defense Weekly*. The program has been called the "American Woodpecker" because its Soviet counterpart is known as the "Russian Woodpecker." The interference this system causes in shortwave communications resembles the pecking of a woodpecker.

The American OTH-B would have had a range 10 times greater than that of conventional radar, and served as an early warning system. General Electric was to build four systems spanning the Northeast, West Coast, Alaska, and north-central states. The decision to scrap this project will help alleviate the fear of increased QRM to HF communications on the ham bands. TNX *Westlink Report, No. 602. (The major details of the OTH-B project was reported in "QRX" in the August 1990 issue.)*

No-Code ROs

Where it can legally do so, the FCC is relaxing its rules which require radio officers with Morse code proficiency on board ocean-going vessels. Recently, the Commission amended its rules to permit small passenger ships weighing under 100 gross tons to operate under the general exemption from the manual Morse code radiotelegraph station requirements beyond the current 100 nautical mile limit. TNX *W5YI Report, Vol. 13, Issue 12.*

Poor Man's Packet

A complete software TNC for PC compatibles!

F. Kevin Feeney WB2EMS and Andy Payne N8KEI

Poor Man's Packet (PMP) was conceived in the fall of 1988. Andy Payne N8KEI, an electrical engineering student at Cornell University, wanted to get into packet but a TNC wasn't within his student's budget. He was sure he could write a software TNC for IBM PCs and compatibles. I'd been involved in packet for several years, but I wanted a more compact means of operating portable with my new laptop computer—like a software TNC running on the laptop with a small modem interface. Andy and I ran into each other on the local repeater, met to exhange ideas, and PMP was born.

A regular TNC consists of a dedicated microcomputer, some software in ROM, a simple Bell 202 modem, perhaps an HDLC chip or a Data Carrier Detect (DCD) circuit, and some "glue" chips to tie everything together. Most people then hook up this specialized little microcomputer device to a personal computer of considerably more power and capacity. The processing power of the PC is mostly wasted, used only to loop on a simple terminal program, shuffling keystrokes to the TNC and bytes from the TNC to the screen.

What is PMP?

PMP approaches the task from a different direction, using the PC to do the work of the dedicated microcontroller. The software is on disk instead of in ROM. Hardware HDLC and DCD circuits are nice, but not necessary for simple TNC implementation. The modem is a simple, one-chip, external design that the software accesses via the handshake lines on the printer port. The terminal interface functions are built right into the program, with direct access to the screen and keyboard. Instead of storing operating parameters such as callsign, transmit delays, or number of retrys in a non-volatile memory like a regular TNC, PMP reads them in on startup from a configuration file.

Using this design, you can build a simple, inexpensive packet communications system. PMP won't support multiple connects or act as a black box TNC for use as part of a BBS, but it's good for the usual connections to the local BBS to read and post mail, for getting your feet wet in packet, and for portable or emergency operation. *[Ed. Note: The PMP program is available from the author as well as the 73 BBS at (603) 525-4438.]*

How It Works

To transmit a packet, the software builds the packet up from the entered data. It then commands data bit D1 (pin 3) on the printer port HIGH, turning Q2 on and keying the radio. Then the software begins toggling the D0 bit (pin 2) back and forth, sending the packet "flags" to open up the distant receiver and synchronize the demodulator. After the flags are sent, the software sends the actual data in the packet, then more flags at the end. Finally, the software turns off D1 and the radio unkeys.

Receiving packets is a little more complicated. While the radio is squelched, the Carrier Detect output (CDT—pin 3 of the 3105) is held LOW. The software "watches" this by looking at the printer port BUSY line (pin 11) indicating that packets are presently incoming, which frees the software to handle the keyboard processing, disk operations, and screen updates.

When the radio unsquelches and sufficient audio starts coming into the chip, the CDT line goes HIGH, signalling the software to "drop everything" by disabling interrupts. It starts timing the 1 and 0 transitions coming from the modem on the Receive Data line (RXD—pin 8 of the 3105).

It does this until the radio squelches and the CDT line goes high again, at which point the software translates the data it has just received from NRZI bit flips into ASCII and displays it on the screen. The program then goes on to handle the other tasks that were shut off during the incoming packet.

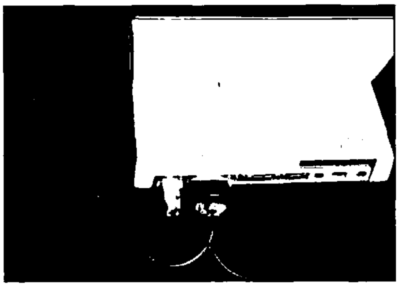

Photo A. Portable packet without a TNC!

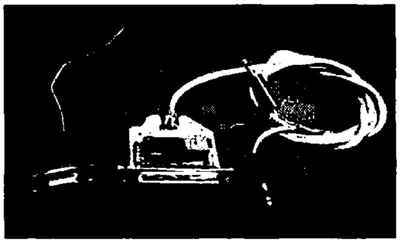

Photo B. The interface installs easily between your computer and radio.

The Modem

While Andy was cooking up the software, I started building modems. I evaluated several of the chips available. The EXAR 2211/2206 are used in several commercial TNCs, but they can be finicky to tune and keep tuned, and I was concerned about temperature swings while portable.

The AMD 7910 World Chip offers several modem frequencies, including some suitable for HF packet, but it's physically large and requires three operating voltages.

Texas Instruments' TCM3105 won out. It has a Bell 202 half duplex modem that requires a minimum of external parts, crystal controlled stability, and low current drain, all in a 16-pin DIP. The final circuit is shown in Figure 1.

Starting in the upper left, U1, a 78L05 miniature voltage regulator drops the incoming voltage to 5 volts for the modem chip. C1 keeps the regulator stable when the power source is more than a few inches away.

Pin 2 is the clock drive output. To generate Bell 202 tones, the TCM3105 requires that an inverted clock be fed into Pin 5. The clock drive from pin 2 is fed into the base of Q1 through R4 to limit the base drive, and the inverted output is taken off the junction of the collector and R3, and fed back into Pin 5.

Pin 3 is the Carrier Detect output from the modem. The TCM3105 senses the audio energy coming into it and raises the line HIGH when the audio is sufficiently strong. Andy's software reads this line via the BUSY line of the printer port (pin 11), and starts trying to decode incoming packets whenever it is HIGH. The chip does not do any filtering or check to see if the incoming signal has the proper tones; it simply reacts to audio level. This means random noise or an unsquelched receiver can trip the line and start the sofware trying to decode. Unlike more complicated circuits with a DCD detector, PMP depends entirely on the radio's squelch to tell when an incoming packet is arriving.

Pin 4 is the receive audio input. C3 provides AC coupling so the internal bias network in the chip isn't dragged down. Initially I had very poor receive results until I figured out I had forgotten this capacitor.

D1 and D2 provide clipping of the signal to protect the modem's input circuit if the audio is

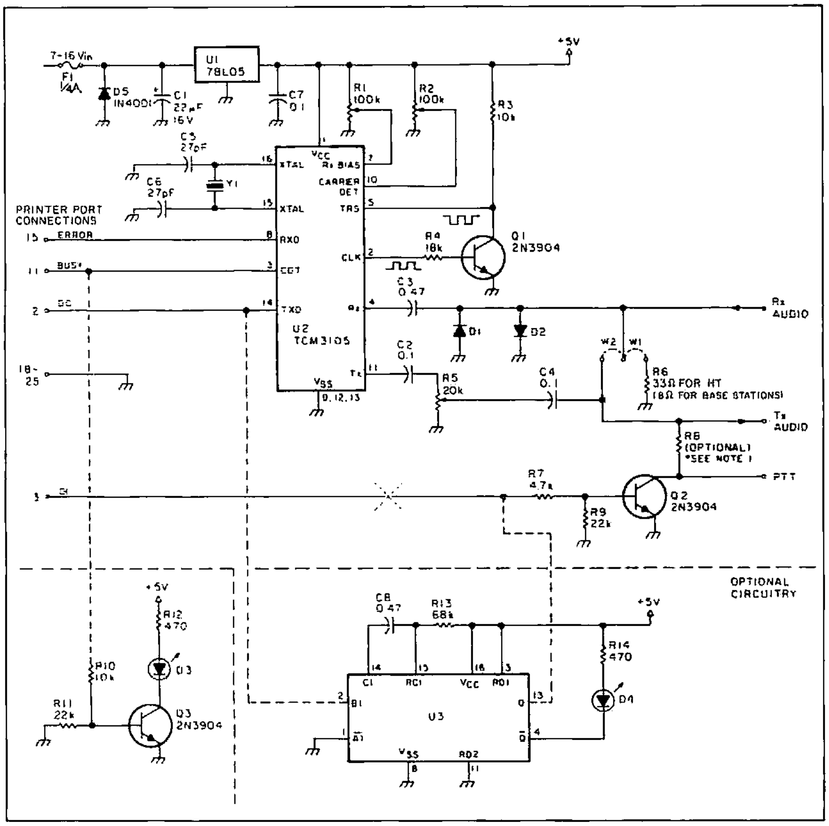

Figure 1. Schematic diagram of the modem interface. The bare bones laptop interface is shown above the dotted line. Use the whole schematic for the home station interface (includes a watchdog timer circuit).

cranked up too high. Even with an HT it's possible to develop enough voltage to damage the chip. The diodes limit the voltage to about 600–700 mV peak. Resistor R6 provides a load for the receiver. Since I generally use my modem with an HT, I put 33 ohms at R6 since that is a good match for the HT's output impedance and takes less power from the rig to drive. If you are operating with a base or mobile radio, you may want to change this to 8 ohms, and make it a 1 watt resistor, in case the audio gets cranked up by accident. This is easy to do when you aren't actually listening to the signal.

Pin 7 is the Receive Bias threshold adjustment. The voltage here determines how the incoming tones are divided into ones and zero. It requires careful adjustment. A 10-turn pot is recommended for fine adjustments.

Pin 8 is the Received Data output from the modem to the computer. It sends the ones and zeros from the modem to the software via the printer ERROR input line (pin 15 of the printer port).

Parts list

U1	78L05	5-volt regulator
U2	TI TCM3105JL	1200 bps half duplex modem chip
U3	74LS123	one-shot mullivibrator
Y1	4.433619 MHz crystal	European colorburst frequency
Q1,Q2,Q3	2N3904	or 2N2222, etc.
D1,D2	1N914 or 1N4148	switching diodes
D3,D4	LEDs	red for D4, green for D3
D5	1N4001 diode	
C1	22 µF, 16V	tantalum capacitor
C2,C4,C7	0.1 µF	
C3	0.47 µF (0.33 to 1 µF can be used)	
C5,C6	20 to 30 pF	
C8	0.47 µF	
R1,R2	100k trimpot	multi-turn
R3,R10	10k	
R4	18k R5	20ktrim pot
R6	33 ohm for HT use	8 ohm, 1 Watt for base/mobile use
R7	4.7k	
R8	4.7k to 12k (10k nomimal)adjust for keying HT (optional)	
R9,R11	22k R12,R14	470 ohms
R13	68k	
F1	¼ amp fuse	

Most parts are readily available, with the exception of the modem chip and crystal. These can be obtained from your local Texas Instruments distributor. F. Kevin Feeney WB2EMS can supply a chip/crystal pair for $24 as well as blank PC boards for $7 each (see author's bio for address). Kits may also be available. Contact the authors for details. The software, including source code, is available from the authors on disk for $10 and from various sites on Internet. You can also download PMP from the *73* BBS at (603) 525-4438. Look under the *73*MAG SIG.

Pin 10 is the Carrier Detect threshold adjustment, similar to pin 7 but not as critical in adjustment.

Pin 11 is the transmit audio output from the modem. C2 provides AC coupling, R5 allows adjustment of the audio level, and C4 breaks the DC path to the transmitter in case it has a DC bias, like the input circuits of many HTs.

Pin 14 is the transmit digital data from the software to the modem. It comes out from the D0 bit (pin 2) on the printer port and causes the modem tone output to switch between 1200 and 2200 Hz with the zeros and ones.

PTT for the modem is arranged by driving the D1 bit of the printer port (pin 3) HIGH. This output drives Q2 through R7, pulling the transistor's output LOW and keying the rig. Q2 can handle about 50 mA. For use with ICOM style HT keying, resistor R8 should be connected between the transmit audio line and the collector of Q2.

For radios with separate PTT lines, R8 should be eliminated. I have found values between 4.7k and 12k to work well at R8. If the resistance is too high, the radio won't key reliably. If it's too low, the transmit audio may be shunted to ground. In using the modem with an ICOM HT, I found that if the transmit gain is set too high, the radio will key as soon as the microphone plug is installed. I believe this is due to the negative-going swings of the audio pulling current from the HT keying circuit and turning it on. I just adjust the transmit gain pot R5 until the radio unkeys. At that level it is far too high for proper modulation anyway.

Assembly and Tuneup

I have built a number of these modems in different configurations. If you are brave of heart and steady of hand, it is possible to cram the entire modem into a DB-25 connector housing, which can then plug directly into the back of a laptop with only a cable to the radio. I've managed it twice, and if you can steal power from the serial port to run it, it makes the sweetest little portable packet setup you ever saw. If you do try it, start with a 16-pin DIP socket and get the smallest pots you can. Mine has a couple of layers of components in one area, separated by tape. Be creative and know it *can* be done.

For those less fanatic builders, the modem can easily be built on a 1.6" x 2" piece of vectorboard. You can either attach the board directly to the DB-25 connector by wedging the board between the rows of pins and applying some epoxy (after making the required connections!), or you can separate the board and the connector with a short, 5-wire cable. Parts layout on the modem is not critical, except to keep the connections around the crystal short. I have built 10 modems with six different layouts from "crammed" to "wide open spaces," and none has failed to work.

A PC board is available to help in assembly (see the Parts List and Figures 2 and 3). Two versions of the modem interface are shown. The smaller board in Figure 2 is designed for portable laptop operation. While the larger circuit shown in Figure 3 can be used for portable laptop use, it is best used for a home computer installation where you plan to leave the modem interface hooked up for long periods. The home interface draws more current and needs a separate power supply (either from a 9-volt battery or DC wall supply).

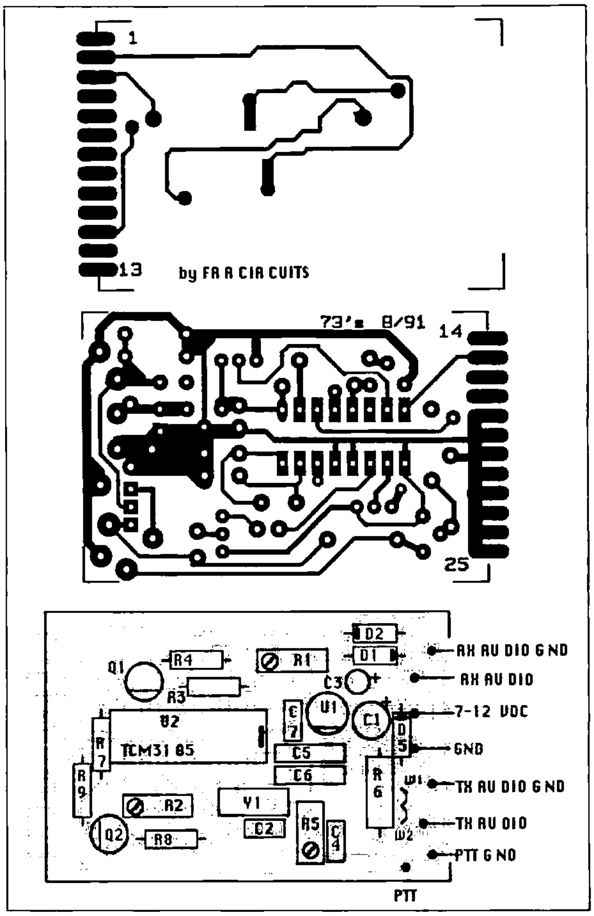

Figure 2. PC board foil pattern for the laptop interface. (a) Top layer (solder the top pads as well as on the bottom). (b) Bottom layer. (c) Parts placement.

Why two versions of the modem? In the interest of portability, the laptop interface lacks a time-out circuit to make it as small as possible. It is designed to be hooked up only when you want to operate packet. The problem is that when you exit the PMP program (or if the computer resets itself), the laptop interface may key down your transmitter continuously (a detailed explanation of this appears in the "Enhancing PMP" section of this article). This is not a problem when you are actually running the PMP program, however. The larger home station interface (Figure 3) solves this with a watchdog circuit and can be left hooked up to your parallel port indefinitely. Just remember: **When using the scaled-down laptop interface, always disconnect it from your computer when you're done operating packet!**

To assemble the laptop interface, just slide the PC board between the rear pins of the DB-25 connector and solder in place. Install the components and make up cables to run to your radio. The interface can be powered by running a cable over to the serial port.(See Figure 3 for serial port connection).

The laptop interface board will fit into the Radio Shack transmitter case (RS # 270-293). The end panel of the case should be notched out to mount the DB-25 connector. Use washers to space the connector away from the end panel far enough so that the PC board just fits into the compartment. This "transmitter case" has an internal space specifically designed for an optional 9-volt battery as well.

The home station modem interface requires a larger case. Also you will have to wire up a cable to run over to your computer's parallel port. See Figure 3 for details.

Checkout and Adjustments

After construction is completed, apply power to the modem with the TCM3105 chip unsocketed. You should have 5 volts on pin 1. If not, check the regulator chip U1 and associated wiring. Check pin 7 and adjust R1 initially for a voltage of 2.26 VDC. Check pin 10 and adjust R2 for 2.5 volts. Next, remove the power and insert U2. Connect the modem to the computer and the receive audio line to the radio. Don't connect the transmit line at this point. Boot up the computer, load the disk, and type PMP to start the program. When the title screen appears, press any key to go to the operating screen.

To adjust the Carrier Detect threshold pot, R2, connect the receiver and squelch the radio. Turn R2 until the RX indicator in the lower right corner of the screen disappears. The RX indicator is tied to the operation of the CDT line. It indicates when PMP starts to attempt decoding packets. Now unsquelch the radio and turn up the volume until it reappears. Resquelch the radio and be sure it disappears immediately. The object is to have the CDT line quickly and cleanly follow the operation of the radio's squelch. If R2 is set too close to the threshold, the CDT line will not follow the closing of the radio's squelch quickly enough. If the RX symbol on the screen never goes away, make sure you have the modem plugged securely onto the printer port, that it has power applied, and that pin 3 of the modem chip is wired correctly to pin 11 on the printer port connector.

To set the RX bias, set R1 for a reading of 2.26 volts at pin 7 of U2; that is a good starting value. When you begin listening to actual packets, if they are not being printed on the screen, you can rock R1 back and forth until you start copying packets. It helps to have a nearby friend send a bunch of beacons or unprotocoled packets for this. Andy has written a supplementary program called PMPTEST that simplifies this process by giving an indication of how closely adjusted R1 is. Using the program and listening to on-the-air packets will get R1 dialed in pretty quickly.

To adjust the transmit audio, send packets while listening on a second receiver. Adjust R5 until the audio stops increasing, then back it off until the audio just starts to diminish. This should put you near the edge of limiting and give you the cleanest audio. The adjustment isn't very critical, but if you are having problems communicating with a particular station, you may need to rock it a little near that threshold of limiting to account for the "twist" between the 1200 and 2200 Hz tones.

Easy Operation

To set up PMP for operation, you first have to edit the configuration file. This is where you tell PMP your callsign, and other information, such as how long you need to wait for your transmitter to key up—the same information you have to provide any TNC before operation. The default information will work for most users, needing only the correct callsign entered. This can be done with any ASCII text editor. The software supplied on the disk contains a program to build your configuration file automatically.

PMP is simple to use. Just hook up the cables to your radio, and plug the interface into your computer's parallel port. Hook up to the serial port for power if you aren't using a 9-volt battery (only for the laptop interface version). Insert your PMP disk and type PMP at the prompt. Hit enter after you see the opening screen and you're ready to go! Andy has simplified a lot of the commands to be single keystrokes. For instance Alt-C commands a connect, Alt-D a disconnect and Alt-H displays the help screen. Hit Alt-L to start capturing a text file. Hit Alt-L again whenever you want to close the capture file. See Table 2 for a complete list of commands. ASCII uploads and downloads are possible, and the scrollback buffer is as large as available memory. One operator in our area lets PMP monitor all day long, and simply walks back through the day's packets a screen at a time to view messages flowing in and out of the area BBS.

Table 2. PMP Commands

Alt-C	Connect
Alt-B	Send Beacon
Alt-D	Disconnect
Alt-H	Show the help screen
Alt-J	Copy a snapshot of the current screen data to a file
Alt-L	Download/Capture a text file
Alt-N	Show a list of nodes recently heard
Alt-P	Pause the screen
Alt-S	Show the system status
Alt-U	Upload a text file from disk
Alt-W	Write the scrollback buffer to disk
Alt-X	Exit PMP
F1-F4	User definable macros
Up/Down	Scrollback a line at a time
PgUp/PgDn	Scrollback a page at a time

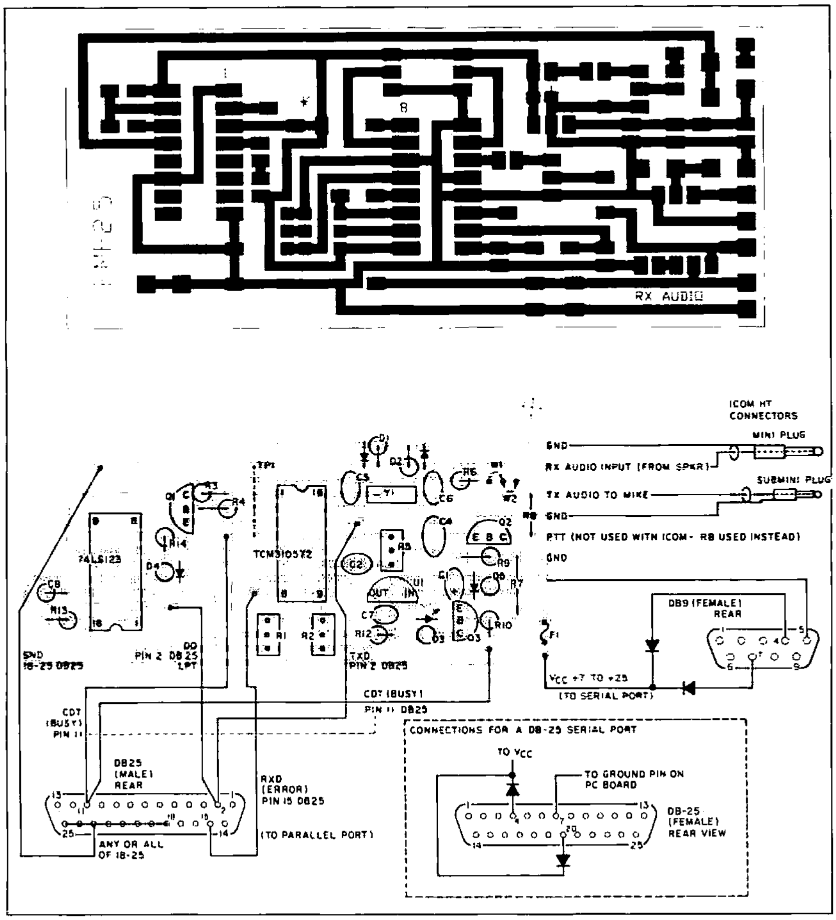

Figure 3. (a) PC board foil pattern for the home station interface with watchdog timer circuit. (b) Parts placement.

Possible Problems

Because of its simplicity, PMP is not quite as foolproof as a full-featured TNC. One potential problem area would be a slow squelch on a radio. Since PMP does not use a DCD (Data Carrier Detect) circuit, it depends on the squelch in conjunction with the CDT line from the modem to tell it when a packet starts and ends. A slow squelch opening may clip the packet header with the callsign information off, rendering the packet unusable. A slow closing squelch is less of a problem because the software can tell by the ending flags where the packet terminated, but the computer remains frozen from responding to the keyboard or displaying the packet until the squelch closes and the CDT line goes low again. The rule of thumb is to put the squelch close to the threshold of opening to help the speed.

The second potential problem is related—performance on a very busy channel. Because of the simplicity of the hardware, the software is very heavily tasked during receive periods, literally timing and counting the bit flips from the modem. Allowing a keyboard interrupt or other distraction during this period would cause the system to lose track of the packet it was in the process of receiving, so all the interrupts are masked off when CDT is high.

On a very busy channel, CDT will go high with each packet heard, and if there is near continuous traffic this can effectively lock the user out of the keyboard! (This will also happen if the radio becomes unsquelched accidentally, or if the modem falls off the parallel port, allowing the CDT pin to float HIGH.) In urban areas it can make things difficult. The only solution is to wait until the channel activity calms down, or pick a less busy frequency.

PMP has been checked out on a fair sample of IBM PCs and compatibles. It does require pretty good compatibility with the IBM standard. Some problems have been reported with machines that have known IBM compatibility problems, such as the ATT PC6300. A partial list of machines it is known to work on includes an IBM PC/XT, Toshiba T1000, Leading Edge Model D, Tandy 1100FD, WYSE PC286, and various 286 and 386 machines using Award BIOS. It even runs in a window under Desqview on my 386 machine.

Enhancing PMP

Figure 1 shows the schematic for the simplest version (the laptop interface) of the modem (the circuit above the dotted line), designed to be hung on the back of a laptop. However, there are a few enhancements below the dotted line that might be of interest (the home station interface).

The radio PTT line is keyed by a signal from the software via the D1 data line on the parallel port; but D1 is only under control when PMP is actually running. If you want to leave the modem and radio connected at all times, you may find that D1 is turned on by other programs, or following a reboot, which inadvertantly keys the transmitter. At times, you may also wish to leave the computer unattended, perhaps to monitor traffic on a channel. An accidental reboot from a power loss could leave D1 in an unknown state and the transmitter keyed.

To address this, U3 was added to form a time-out timer. U3 is a 74LS123 one-shot multivibrator with edge-triggered inputs, whose output circuit is used to drive Q2 instead of letting PMP control it directly. The output of the one-shot stays LOW until pin 2 goes HIGH, then it raises its Q output, turning on transistor Q2. The output only stays HIGH for about 10 milliseconds, unless pin 2 goes LOW and then HIGH again. Pin 2 is connected to the tranmit data from the PMP program. When PMP is running and sending data to be transmitted, the data line connected to pin 2 is toggling at about a 600 Hz rate. Each transition resets the time-out on the one-shot, keeping its output HIGH and the transmitter continuously keyed as long as data is being sent. When the flow of data stops, pin 2 stops changing state, and the one-shot times out 10 milliseconds later, unkeying the transmitter.

If the program locks up, or the computer resets, or if another program is being run, D1 will likely sit at either a one or a zero, but it probably won't be toggling at 600 Hz. So, the transmitter will only burp for 10 milliseconds if D1 goes HIGH, and then it will stay off. D4 and R14 use the /Q output of the one-shot to provide an optional keying indicator.

The circuitry associated with Q3 and D3 also provides for a receive LED. The base of Q3 is tied to the Carrier Detect (CDT) line of the modem chip, and when it goes HIGH indicating received audio, Q3 turns on, causing D3 to light. I use a green LED for D3, and a red LED for D4.

For portable operation, the bare bones modem has a low enough current drain that you may be able to steal enough power from your computer's serial port to run it (or use a 9-volt battery). The PMP configuration file has provisions that allow you to command the handshake lines of the serial port to a desired state. In my case, I command both the hardware handshake lines HIGH and OR them through a pair of diodes to provide about 7 volts at 12 mA, just enough to give me 5 volts out of the regulator. The voltage and current available from the CTS and DTR lines varies from machine to machine, but if you can do it, it reduces the entire packet setup to a computer, a cable and a radio. I have not seen anything simpler for portable packet! Because it is so simple to drag around compared to other packet systems, I find myself running packet from all kinds of locations—the park at lunchtime, a weekend campsite, or even the laundromat!

Poor Man's Packet has achieved both of the goals we set out to accomplish. Andy now has an inexpensive system to allow him to join local packet operations, and I have an easy-to-use packet system for portable operation.

Laguna Niguel CA 92607-6418
(714) 496-6639
Price Class: $60

Your software window into the world of digital communications!

I like new software, especially things I can use with my Heathkit HK-232 MBX multimode controller, a PK-232 clone.

Pkt-GOLD Multimode is a program that turned out to be one of the best implementations of multimode controller software that I have seen. In my opinion, the program does a great many things right, or better-than-right, and it all adds up to quite a nice piece of work by the developers at InterFlex Systems.

Installation

For starters, loading and setting up the program on a hard disk is easy. All you do is put the disk into drive A, and type "INSTALL"; the program does the rest. After you answer several questions about such things as baud rate, communications port, video adapter and the like, as well as filling in your call, you are ready to go by typing "PKTGOLD" at the system prompt.

Pkt-GOLD Multimode takes full advantage of AEA's "host" mode—perhaps the most robust implementation of "host" mode on the market. It allows you to keep the memory backup batteries in place during power-up. AEA's own software indicates that you have to pull out the batteries to prevent software hanging up, but Pkt-GOLD Multimode lets you leave the batteries in place. Pkt-GOLD Multimode emulates the PK-232's architecture in software, which makes your PC's RAM look like a multimode controller. To the controller, it doesn't make a bit of difference where it gets its information from, whether the information comes from its own buffers or your PC's RAM. Pkt-GOLD Multimode attempts to retain any text that might be in any of your controller's buffers. If it does not find text, after checking several times in an effort to avoid a RESET command, it then has to load the buffers with program and textual information and this takes time.

I found that InterFlex's advice was well-taken as I tried using my controller both without and with batteries. Without batteries, and if the TNC was turned off, the initialization process took the better part of a minute. With the batteries, the initialization took about five seconds because the controller was set up and ready to go with parameters that I had already entered.

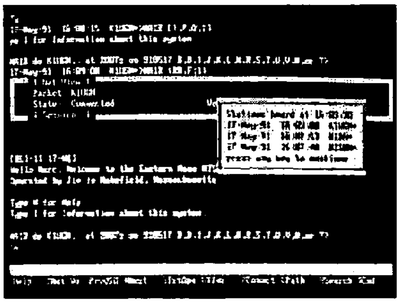

Photo A. While you're connected to another station, Pkt-GOLD's versatile features allow you to monitor all of the channel activity. All activity is displayed at the top of the screen (Net View); your connect session is displayed at the bottom portion (Session). Pop-up screens are available at any time. For example, pressing <ALT> F2 gives you the current MHEARD list.

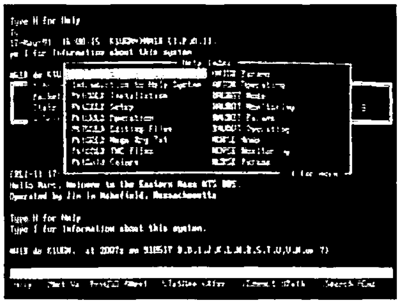

Photo B. The help screen is available at any time as a pop-up menu.

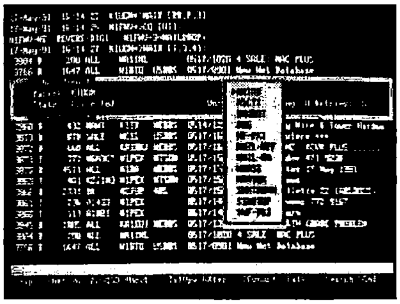

Photo C. Pressing function key F10 allows you to quickly change modes.

The bottom line is to put the batteries back in the TNC. This saves Maildrop messages in case of power loss, and offers some other advantages as well (like not losing your callsign, alias, and other settings if there is a brief power loss, or if you turn off your TNC and turn it back on). With the batteries installed, Pkt-GOLD Multimode zipped through the initialization. A pop-up window displayed the parameters that Pkt-GOLD Multimode was loading into memory from the default ASCII text file, called "Startup.TNC." If the Startup.TNC file is edited to bare bones start-up parameters, the initialization is virtually instant.

A Versatile Program

Pkt-GOLD Multimode's development team, Lynn Taylor WB6UUT and Jeff Towle WA4EGT, have put lots of nice things into their software.

For starters, the user interface is clean and intuitive. There's a brief listing of the function keys at the bottom of the screen. The ALT key changes the functionality of those keys. The user interface also offers a split screen that lets you monitor what is going on with sessions other than your own, as well as of your own. It's like having an eye on the frequency you are using, as well as on the station you are trying to contact.

It's easy to see that this software is powerful. For example, when I was using Pkt-GOLD Multimode for multi-connects, I found that when I pressed the CTRL key on my PC, I saw a number of channels indicated at the bottom. In several of those channels I saw the stations that I was trying to contact. When I was multi-connecting, the program latched onto the station with which I was trying to connect and assigned It a specific memory location, or "channel." Also, if you are doing a multi-connect, a few keystrokes will put these stations into one or more conferences, which is great for emergency situations or general round-table discussions.

Pkt-GOLD Multimode is loaded with utilities. I found that not only could I log onto my favorite bulletin board and my home BBS, but I could also log onto other stations at the same time. All I did was type in the callsign of the station I wanted to connect to, hit the F7 func-

RF POWER AMPLIFIERS

MODEL 1410G

MODEL 1450G

All amplifiers (non-rptr) are linear, all-mode with telly automatic T/R switching and PTT capability. The receive preamps use GaAs FET devices rated at .5 dB NF with +18 dBm 3rd order IP. LPA, Standard and HPA amps are intermittent duty design suitable for base and mobile operation. Repeater amps are continuous duty, class C.

Amplifier capabilities: High-power, narrow or wide-band; 100-200 MHz, 225-400 MHz, 1-2 GHz. Military (28V), Commercial, etc. – consult factory. A complete line of Rx preamps also available.

RX Preamplifiers

Band	Model	NF (dB)	Gain (dB)	Connector
50 MHz	0520B	.5	25	BNC
50 MHz	0520N	.5	25	H
144 MHz	1420B	.5	24	BNC
144 MHz	1420N	.5	24	N
220 MHz	2220B	.5	22	BNC

CIRCLE 232 ON READER SERVICE CARD

tion key, and then switch sessions with the F4 function key. Each session would alert me if there was mail or traffic waiting with a flashing prompt on the graphics screen. I was then able to personalize things by going back to each session with the F4 function key and, by using ALT-N (name) keys, type In the operator's name which then appeared next to the callsign on each session screen.

Using the "next" key [F4], I was able to cycle through the sessions easily. Note that each session was individual and any text I typed was used only by the particular session I had attached to. Pkt-GOLD Multimode also has "cut and paste" features that allow you to transfer text to another station. For example, I cut text from an AMTOR session, and sent it to the local packet BBS after editing it using the clipboard editor. Also, printing to a printer or file is easy using [Alt-P]. Printing can commence from the beginning of the screen buffer (which can be as much as 300K), or you can just print new text.

The program also supports saving session text on a callsign-by-callsign basis. You tag certain sessions as "important," and every time that station connects, text is saved/appended to a file with the callsign as the file name. These are certainly useful features for emergencies or situations requiring backup documentation.

There is no special screen to go to, but you can enter a full screen parameter editor if you wish. Changing one or a few parameters is done easily by typing the parameter and value, and using the CMD key [F10]. Basically, you use the [Enter] key to send things THROUGH the controller over to the other station, and the [F10] key to send things TO your controller, such as parameter changes or new settings.

Pkt-GOLD Multimode also understands how to use NET/ROM for hopping from node to node. Connecting to a node and requesting a circuit to the next node takes time. Pkt-GOLD Multimode does the waiting and automatically issues the subsequent "connect" requests for you. You just type something like this: CNODE1 | NODE2 | NODE3 | W2ABC and Pkt-GOLD Multimode handles all the interim node connects, getting you to W2ABC. As it progresses through the node system, each successful connect results in a CW message and a pop-up screen telling you of the progress through the node system.

You can also set up "quick connects" with these multi-hop "path" statements and simply hit the [F7] connect key, highlight the target station, such as "W2ABC," and the program does the rest.

An interesting feature of NET/ROM is that you may have multiple connects to a single node by using its node alias. If you connect to the node using the station callsign, NET/ROM allows only a single connect. However, if you connect to a node using its alias (e.g. "GR-BOX" instead of "WA1R-2") NET/ROM will allow up to 15 multiple connects using the "alias-n," where "n" can be up to 15. Pkt-GOLD Multimode understands this, and allows you to use the same set of NET/ROM nodes to establish many sessions. It automatically assigns unique sessions with the entry node by assigning different SSIDs, the number after the "alias" name.

Multiple Features

Perhaps the neatest thing I found is Pkt-GOLD's ability to implement all the modes of the controller.

Pkt-GOLD Multimode takes advantage of the ROM that is already in your controller. With Pkt-GOLD Multimode, you can use the same friendly program features on all of the other modes available. If you have a PK-232, you can use AMTOR, NAVTEX, RTTY, Morse, TDM (Time Domain Multiplexing, a new PK-232 mode in which several signals are able to use one frequency by digitally shifting their timing slightly), packet, and the PK-232's patented SIAM mode. Changing modes is a snap.

Pkt-GOLD Multimode also offers protocol file exchanges for error-free transmission of any file, while allowing keyboard-to-keyboard conversation on the same channel, and of other multiple connects, all at the same time. You can get remote user directories and, while transferring a file, the program shows the remaining time and the effective baud rate of the transmission to other stations requesting files. It also provides file transfer statistics to these other stations, estimating when the file transfer will be finished.

For those with PK-88 controllers, Pkt-GOLD Multimode offers all of the powerful features that it does on the PK-232 (for packet mode). Briefly, some of the other features are "Brag" file support for longer descriptive messages, and [Alt-0..9] keys for one-line messages, both supporting macros such as "?callsign" to fill in the other station's callsign, or "?name" to fill in the remote user name, to make messages appear to be personalized.

Well Worth the Money

To say that I like this program is putting it a little mildly. I tested Pkt-GOLD on my PC clone (EGA monitor, 640K of RAM, 80286 CPU, hard disk). It also supports VGA and other enhanced video display cards. The program runs flawlessly at the highest terminal baud rates of 9600 for the PK-232 and 19200 baud on the PK-88. It has an integrated set-up area, accessed with the [Alt-S] key combination. This is where you enter quick connects, station information, and set many of the program refinements like 25/43/50 line screen mode color settings, size of the NetView screen, pop-up window time, Morse code announcement speed, file paths, and the like.

Pkt-GOLD features pop-up displays and menus galore. The documentation is clearly written and leads you quickly through the features of the program. In addition to the printed book, you get a complete online help system that is context-sensitive and hypertext.

You can learn about operating modes, parameter settings, frequencies, even how to tune up the controller and radio for maximum performance, by perusing this multi-page cross-referenced help system.

Overall, if you are looking for a reliable, solid system, I would say Pkt-GOLD Multimode is more than worth the price, much more than worth it!

Low Cost Discone Antenna

Wideband coverage from 144 to 1296 MHz.

by Phil Salas AD5X

I needed an antenna that would satisfy a lot of needs. After purchasing an ICOM R-7000 receiver (25–2000 MHz) for some experimental work in the UHF and low microwave ham bands, I wanted a good broadband antenna that I could easily mount in my attic and that would provide coverage of the 144, 220, 450, 903, and 1296 MHz ham bands. I also needed this antenna to provide a good match so that it could be used for transmitting within these ham bands as well. Though this sounds like I'm asking a lot, there is a broadband antenna that can satisfy these needs: the discone antenna.

The Discone Antenna

When properly designed, a discone antenna provides decade (10:1) frequency coverage with a good match (see Figure 1). The discone consists of a disk (the driven element) mounted over a conical ground plane. The cone is an equilateral triangle whose dimensions are a quarter wavelength at the lowest operating frequency. The disk (driven element) has a diameter of 70% of a quarter wavelength at the lowest operating frequency. The disk should be very close to the apex of the cone; the recommended spacing is from 10–30% of the diameter of the apex of the cone.

The trick is to be able to easily realize the cone and disk as well as provide a solid insulated support for the disk and a sound mounting method for the overall antenna. Also, this antenna should be inexpensive, and easily constructed with readily available parts from hardware and Radio Shack stores.

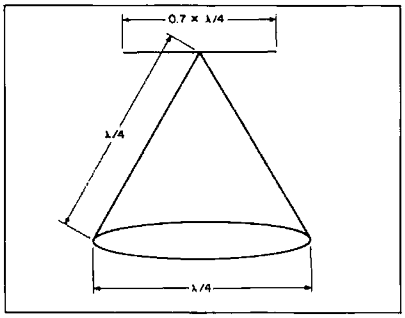

Figure 1. Design for the discone antenna.

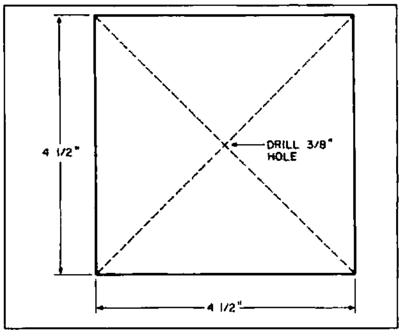

Figure 2. Dimensions of the disk support.

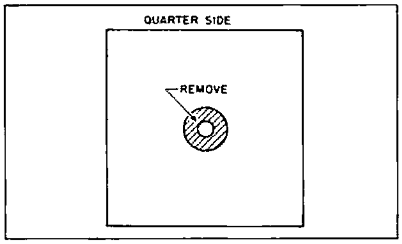

Figure 3. Disk support preparation.

Since I wanted to cover the two meter band, I picked the lower frequency limit to be below the lower band edge. The actual frequency I picked was 137 MHz. A decade of coverage should still give me up to 1370 MHz, which suited my needs. The equation for this is: ¼ wavelength = 2952/137 = 21.5" = cone side; disk diameter = 0.7 x 21.5" = 15".

Now all I had to do was figure out how to build it!

Constructing the Discone

See the "Parts List." The last three items came from Radio Shack. The ⅜" solder lugs are part of the package (two per package) of solder lugs from Radio Shack, but you can save money if you can find ⅜" solder lugs separately. I bought all of the other items in the electrical department of a local hardware store.

Now, let's get to work. We will first prepare all the individual pieces.

The disk support will be made out of the single-sided printed circuit board. First, cut this board into a 4½" x 4½" square. With a pencil, draw diagonal lines from corner to corner on one side. See Figure 2. Drill a ⅜" diameter hole at the intersection of the lines (the center of the PC board). Referring to Figure 3, center a quarter over the hole on the foil side of the PC board and trace around its circumference. Using a sharp X-ACTO™ knife, cut through the copper on the circular lines just traced. Now remove the copper *within* the circle. A soldering gun will aid in removing the copper foil.

The light fixture canopy needs some modification. These kits include a fixture for mounting a lamp on, a short length of 1/8IP threaded steel lamp pipe, and some additional hardware. Refer to Figure 4. Nibble or cut a slot along one side of the canopy at least 0.3" x 0.3". This will pass the coaxial cable when the canopy and antenna are mounted.

Cut all eight welding rods to a length of 21.5". Unless you have heavy cutters, you will need to use a hacksaw. Remove any insulation from the ⅜" solder lugs, insert only one end of the cut welding rods into the solder lug crimp end, crimp the lug and solder. See Figure 5.

Cut the remaining eight short pieces of welding rods to 7¼". Finally, determine the center of the 4" round plastic electrical box cover and drill a ⅜" hole. It is important that this hole be well-centered, so take care in determining this location.

Now take the 30" 1/8IP all-thread steel lamp pipe and carefully tin one end of the pipe. See Figure 6. Be careful not to get solder on the threads of the pipe. This pipe is

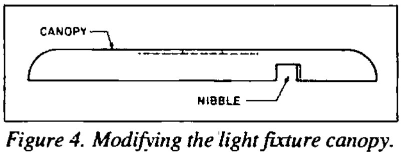

Figure 4. Modifying the light fixture canopy.

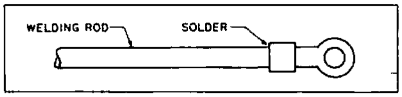

Figure 5. Element preparation.

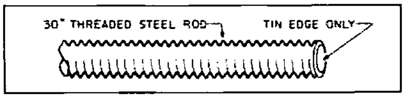

Figure 6. Tinning the pipe.

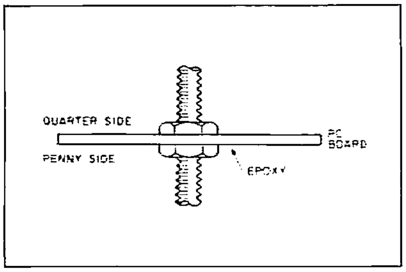

Figure 7. Disk support assembly.

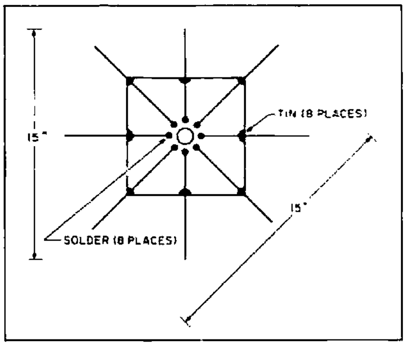

Figure 8. Tinning and soldering the top of the PC board.

not difficult to tin since it is made of steel, which doesn't conduct heat away as fast as copper or brass does. Cut 1" of the outer insulation off the RG-8M coaxial cable, separate the braid, and then fold it back over the cable insulation. Insert this end of the RG-8M cable into the non-tinned end of the 30" lamp pipe and push the cable through until the braid is flush with the tinned end of the pipe. Solder the braid to the pipe at this point.

Next, prepare the disk support printed circuit board. Insert a short length of steel lamp pipe (provided with the canopy kit) through the center hole in the printed circuit board and fasten it securely in place with two brass nuts. See Figure 7. Epoxy the brass nut to the PC board opposite the foil side. Be careful not to get epoxy on the threads. Now, remove the nut from the side of the board not epoxied, and unscrew the steel pipe from the nut still attached to the PC board. The side of the PC board with the nut will now be referred to as the bottom of the disk support PC board.

On the top of the PC board, tin each corner and tin the midpoint of each side. See Figure 8. Now solder down the 7¼" welding rods to the PC board, making sure that the total length from outer point to outer point is 15". You are creating a disk 15" in diameter out of the eight welding rods. Now go back and solder the inside edge of the welding rods to the PC board. Finally, place the 1" diameter brass washer over the ends of the welding rods centered over the hole in the PC board and solder the washer to the rods. See Figure 9.

Now it's time to start assembling the antenna. First, screw the end of the 30" pipe with the RG-8M center conductor sticking out into the nut on the bottom of the PC board. Screw it in just far enough so the end of the pipe is flush with the printed circuit side of the soldered down nut. The center conductor of the RG-8M will pass through the center of the brass washer on the top of the PC board.

Parts List

Description	Approximate Cost
1" diameter brass washer	$ .10
30" 1/8IP all-thread steel lamp pipe	$ 3.17
1 light fixture canopy kit	$ 2.45
6 brass 1/8IP nuts (pkg. of 6)	$ .99
1 plastic 4" round electrical box cover	$ .17
10 feet #12 copper wire ($.07/ft.)	$ .70
8 copper plated steel welding rods ($.20 ea.)	$ 1.60
12" x 24" x 1" piece of wood	$ 1.00
4½" x 4½" single-sided PC board	$ 3.99
6 ⅜" solder lugs (RS 64-3040 x 3)	$ 3.87
5 feet RG-8M (RS 278-1328 0.27 x 5)	$ 1.35
Total	$19.39

Next, place the solder lugs of the eight long steel welding rods over the 30" steel pipe and hold them in place with a 1/8IP brass nut. Put this nut on finger-tight and then arrange each long rod so that it is exactly under each short rod on the top of the PC board. Carefully tighten the brass nut. Thread another brass nut on the steel pipe and position it about 3" below the nut holding the long rods in place. Hold the pipe upright with the PC board at the upper end, then bend all the long rods down along the steel pipe. Place the plastic electrical outlet cover over the steel pipe and thread on another brass nut. Push the electrical outlet cover up the pipe and spread the long welding rods until the bottom ends of the rods are 21.5" apart from their opposite rod. Adjust the nut positions as necessary and tighten the nuts to hold the electrical outlet cover in place. See Figure 10. I used a hot glue gun to attach the long welding rods to the plastic electrical outlet cover to help with the antenna rigidity, but this is not really necessary.

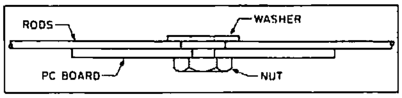

Figure 9. Finishing the PC board.

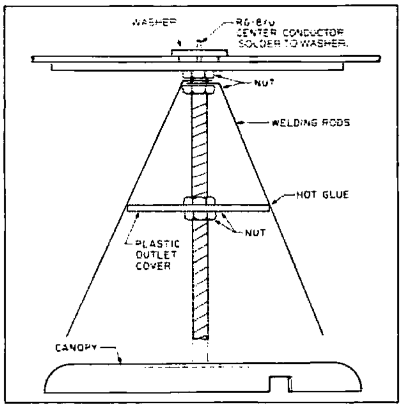

Figure 10. Assembling the discone.

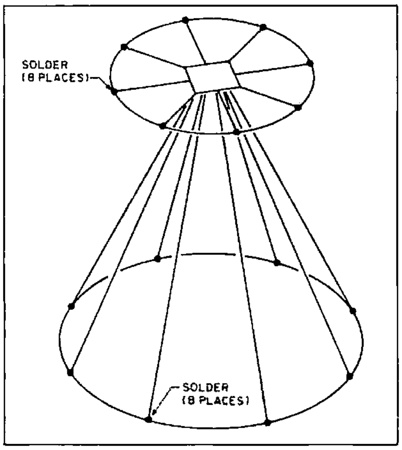

Figure 11. Wire placement.

Strip the insulation off the RG-8M center conductor as it passes through the brass washer on the top of the printed circuit board. Solder the center conductor to the brass washer. Now, mount the antenna to the canopy by threading another brass nut over the end of the steel pipe, passing the cable and pipe through the hole in the canopy, and threading another nut over the pipe and tightening it. You can now attach the canopy to a piece of wood (I used a 1' x 1' x 1" board), thus allowing the antenna to stand freely.

The last thing to do is to solder a piece of #12 copper wire around the circumference of the disk and cone. Cut a 50" piece of wire for the disk and a 70" piece of wire for the base of the cone. Tin the ends of each of the welding rods and solder the copper wire to them. See Figure 11. Though it is not really necessary to tie all the welding rod ends together, this and the hot glue mentioned earlier make the antenna very rigid.

Finally, attach your connector of choice to the end of the RG-8M coming from the discone. RG-8M has the same dimensions as RG-59. A PL-259 UHF connector with a RG-59 reducer or a BNC connector for RG-59 cable work well.

Operation

How does it work? I measured an SWR of less than 1.5 to 1 on all ham bands between 144 and 1296 MHz. I placed the antenna on its wood base in my attic and it provides excellent general coverage reception, as well as transmission in the covered ham bands. Not bad for about an hour's worth of work and less than $20 worth of parts! 73

High Speed Data Acquisition

Sample the outside world with this inexpensive interface.

by Mike Gray N8KDD

Personal computers have made huge improvements in nearly every field, including the scientific and engineering communities, acquiring and processing data for research projects. Hams, too, have made extensive use of computers, and many have an interest in using them for data acquisition.

To do this, all a computer needs is an input device and appropriate software. The keyboard is the most commonly used input device. Data taken manually from individual instruments is recorded on paper and entered later. However, keyboards are unacceptably slow for most projects, so an instrument such as a datalogger or a data-acquisition card is used.

Information stored in a datalogger is usually entered into the computer through the serial port, sometimes by means of a telephone or radio modem. Commercial dataloggers are too costly for most of us to justify the purchase of even the least expensive model.

A bus-oriented data acquisition card installed in a personal computer is a powerful, though expensive way to build a digital data acquisition system. Most portable computers will not accept a data acquisition card, so work is usually confined to a laboratory using a desk computer.

Many projects need only one channel of data, acquired at relatively high speed, and this project will satisfy that requirement at very low cost.

Hacker Method

Another means of getting data into a computer is through the parallel printer port. This port is generally not used for anything but driving a printer, but like most things, it can be adapted (hacked?) to other uses. Data can be transferred much faster in parallel than in serial form.

There are three port addresses at the printer connector of IBM-compatible computers. At 378 (hexadecimal) is the 8-bit data word. This address is all that we'll discuss for now. Address 378 is LPT1, and most compatibles are configured in this manner. LPT2 is address 278 (hex). Some computers may be configured such that the data lines appear at address 3BC (hex); check your manual for

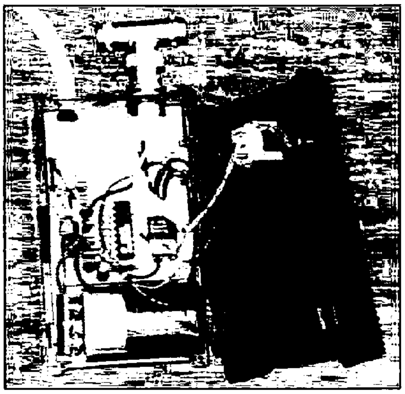

Photo A. Inside view of the A-D box.

the proper address for your system. Note that the BASIC program will have to modified for your computer system's port address if different than 378 (hex).

Printer connector pins 2-9 correspond to data bits 0-7. Pins 18-25 are grounded. If a pin is high, grounding that pin saturates the output driver and the logic state changes from 1 to 0. Communicating over the parallel port in this manner is easy, but it also inverts the conversion result. It's a simple matter to fix that in the software.

A-D Converter

An analog-to-digital (A-D) converter chip converts an analog value to its binary equivalent. The chip requires a reference voltage, against which the analog signal is compared. In most cases, the reference voltage is 5 volts, the same as the supply voltage.

The Data Bit output lines are numbered DB0–DB7. These lines are connected to pins 2-9 at the computer printer connector.

If the analog input voltage is zero, all eight lines will be low (0 volts), and the decimal value of the 8-bit data word will be zero. If the analog input is greater than or equal to the reference voltage, all eight lines will be high (5 volts), and the decimal value of the 8-bit data word will be 255. An 8-bit A-D converter has a maximum resolution of 256 (0-255 counts).

The amount of current required to drive the printer port of many computers is greater

Photo B. The interface hooked up to an IBM PC clone.

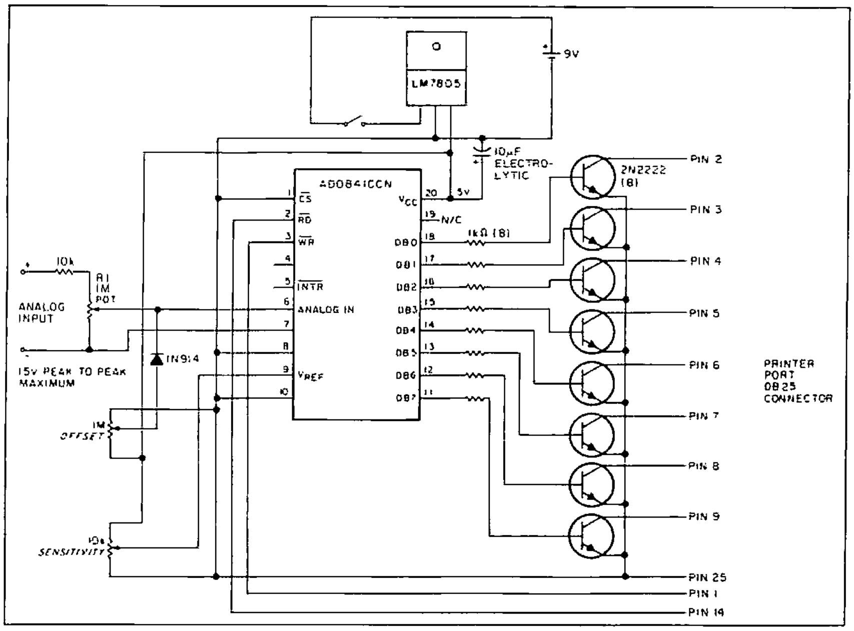

Figure 1. Schematic diagram of the interface.

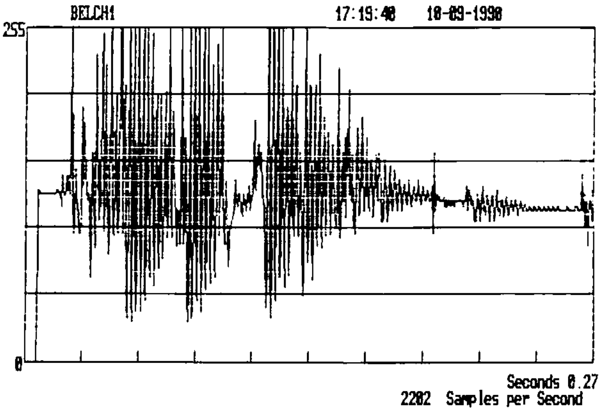

Figure 2. Unusual audio waveform as sampled by the interface.

than the A-D converter chip can handle, so external drivers are necessary. I chose common NPN transistors.

In addition to the data bit lines 0–7, two more lines from the printer connector are required. These control the A-D converter. They are found at address 37A (LPT1), 27A (LPT2) or 3BE on some computers. Pin 1 controls when the chip performs a write (WR), and pin 14 controls when the chip performs a read (RD). Both lines need to be set high initially, then WR is pulled low, which starts a conversion. After WR is asserted high, RD can be pulled low and the conversion result will appear at the output lines.

Precaution

Grounding any of the printer port pins 2–9 pulls the voltage below the threshold necessary for the computer to recognize a logic 1. The logic levels vary, but all are under 0.8 volts. Some computers are capable of driving very high loads, which means that the current required to pull the pin voltage below the logic level threshold could be as high as 60 mA per pin.

In testing five different computer brands, I have not found even one to be damaged by grounding these pins, but the drivers may get warm after a while. In order to protect the computer from any possible damage, the printer port should be held in a high state only long enough to read an input from the A-D converter. The software will accomplish this.

Once completed and working, the converter should not be connected to the computer for more than 10 to 20 minutes, unless the converter is off, the analog input is zero, or the software is running. The software program allows current to flow only long enough to read the port.

Construction

Since the component count is low, the circuit can be assembled on perfboard. The chip is static-sensitive, so mount a 20-pin socket to the board and install the chip only after assembly is complete and the wiring has been checked.

The sample rate is entirely dependent upon the speed at which the computer can toggle the WR and RD lines, and interrogate the printer port. The operation of this chip is described in greater detail in the *National*

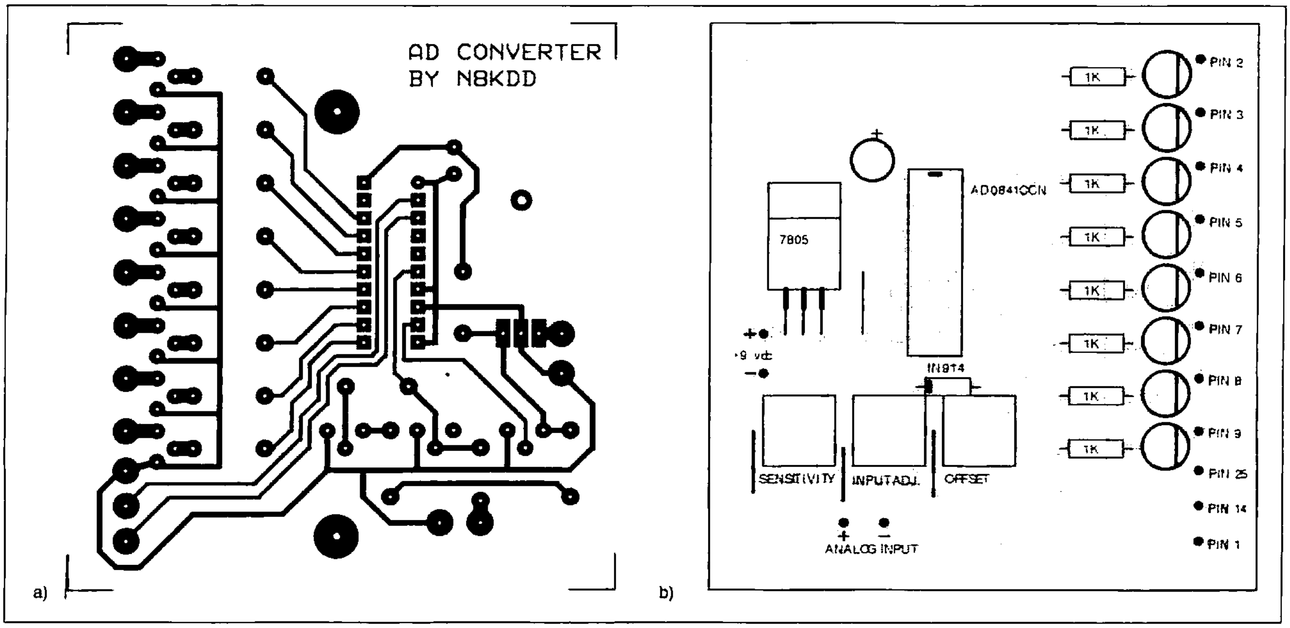

Figure 3 (a). PC board foil pattern. (b). Parts placement.

Semiconductor Linear Databook, Volume 2.

The A-D converter chip may be destroyed if more than 5.1 volts are applied to the input. R1 should be adjusted to divide the input voltage by three, so that there won't be any damage unless the input is greater than 15 volts. The offset and sensitivity potentiometers allow the instrument to measure bipolar inputs, and to measure low level signals with good resolution. If you measure only signals between 0 and 5 volts, all three pots may be eliminated.

Smoke Test

Make sure the power switch on the converter is off, then plug the DB-25 connector into the printer port on the computer. Load BASIC and add the following line to the program listed in the sidebar:

65 Y=255-Y.

(Since the NPN transistors cause a bit inversion, the bits must be inverted again in order to get representative data.) Now run the program listed in the sidebar.

Adjust the offset and sensitivity pots to midscale and turn the power switch on. The display will read something between 0 and 255, depending on where the pots are set. Turn the offset pot and watch the decimal value change.

Software Suggestions

The application possibilities are endless, and everyone has his own particular reason for getting analog information into his digital computer. An experienced Gizmologist should be able to build a custom program around the core program listed in the sidebar.

You can connect many different transducers to your new A-D converter. I have used these transducers with good results: audio, position, displacement, temperature, strain.

The software you write can convert the raw A-D counts to engineering units for you. If, for example, you have a position transducer which produces 5 volts when it is 100 percent extended, simply divide the variable "Y" by 2.55 (Y=Y/2.55).

The computer can make graphs while taking data, although the more you ask the computer to do, the slower it gets. If you want speed, acquire the data first, then plot it. The plot in Figures 2 were made with an IBM AT using the acquire-then-plot technique. The transducer was an audio amplifier. If you measure some slowly changing physical event such as temperature, program execution speed is not of much concern, but an accurate time base is. If you would like a copy of some general purpose, graphic-oriented programs, you can download them free from the *73 Magazine BBS* at (603) 525-4438 or send $6 to me at the address below. Be sure to specify whether you would like a 5.25 or 3.5 inch disk.

A 9 volt alkaline battery will last about six hours in continuous use. You could use a filtered power supply or larger battery pack if you need longer service. ■

Contact Mike Gray N8KDD at 465 W. Maple Rd., Milford MI 48381.

Parts List

1	ADC0841CCN	A-D converter (price is under $10)	Pioneer Standard Electronics, 13485 Stamford, Livonia MI 48150
8	2N2222	NPN Transistors (metal can preferred)	
8		1k ohm resistors, ¼ watt	
1		1 megohm board mount potentiometer	
1		10k ohm fixed resistor	
1		10k ohm panel mount potentiometer	
1		1 megohm panel mount potentiometer	
1	LM7805	5 volt regulator	
1		SPST panel mount switch	
1		9 volt battery clip	
1		10 µF electrolytic capacitor	
1	DB25	Male printer port connector	
1	1N914	Diode	
		About 2 feet of 11 (or more) conductor cable	
1	276-150	IC circuit board (Radio Shack)	
1		20-pin IC socket	

(Most ol these components can be purchased at Radio Shack. You may also be able to order the A-D chip at a local Radio Shack.)

Note: A blank PC board is available lor $4 + $1.50 shipping from FAR Circuits, 18N640 Field Court, Dundee IL 60118.

Port Experiments

In the following experiments, I used BASIC to control the A-D converter and read the printer port. Any other programming language will work, but I like BASIC because it's so easy to use and explain. All of the *.EXE files for my applications were written using Borland's Turbo BASIC™, and the source code is available for those who want to write their own software applications. Turbo BASIC runs about eight limes faster than BASIC interpreter.

The following program reads the bit status at the printer port. The monitor displays the decimal value and bit status of a byte read from the printer port.

BASIC Interpreter (BASICA or GW-BASIC)

```
10 OUT &H37A,12                  'WR and RD high
20 OUT &H37A,13                  'WR low
30 OUT &H37A,12                  'WR and RD high
40 OUT &H37A,14                  'RD low
50 OUT &H378,255                 'latch all bits high
60 Y=INP(&H378)                  'input 1 byte (variable y)
70 PRINT Y,BIN$(Y)               'print Y (decimal and binary)
80 OUT &H378,0                   'latch all bits low
90 Q$=INKEY$                     'keyboard trap
100 IF Q$="q" OR Q$="Q" THEN END 'if user enters q then quit
110 FOR D=1 to 2000:NEXT         'time delay
120 GOTO 10
```

Turbo BASIC

```
do
out &H37A,12                     'WR and RD high
out &H37A,13                     'WR low
                                 out &H37A,12 'WR and RD high
out &H37A,14                     'RD low
out &H378,255                    'latch all bits high
y=inp(&H378)                     'input 1 byte (variable y)
print y,bin$(y)                  'print y (decimal and binary)
out &H378,0                      'latch all bits low
q$=inkey$                        'keyboard trap
if q$="q" or q$="Q" then end     'if user enters q then quit
delay .5                         'time delay
loop
```

You should see 255 11111111 on your monitor. If not, double check the program code and run it again. You may need to change the port address from &H378 to &H3BC. While the program is running, connect a jumper wire between pin 25 and pin 9. The display will now read 127 01111111. The left-most bit is the most significant. It has a value of 128. Connect pin 25 to pin 2. The decimal value is now 254. Pin 2 is the least significant bit of the 8-bit word and it has a value of 1. Try connecting each pin to pin 25, and watch the display. You will see this pattern develop:

Bit	Pin	value (bit high)	
0	2	1	least significant bit
1	3	2	
2	4	4	
3	5	8	
4	6	16	
5	7	32	
6	8	64	
7	9	128	most significant bit

Software for the Ham Shack, Part IV

Useful ham calculations you can program yourself!

by Bill Clarke WA4BLC

This is the fourth, and last, part of this series of articles. The Ham System has grown to be quite capable of saving time and aggravation for the user.

Let's add the last modules to the system. This month the MAIN MENU will grow to nine choices. Added will be:

8 - RESISTOR COLORS TO OHMS
9 - AIR COIL INDUCTANCE

Module Eight

Last month, you added module seven, which gives you the resistor color codes when you enter the value of ohms required. This month, with module eight, you get to do the reverse: Enter the color codes and get the value in ohms.

Module Nine

Have you ever looked in the junk box and come up with an air-wound coil of unknown value? This last module asks for the physical dimensions of the coil, then gives you its value in microhenries. No more unknown coils!

Entering the Listing

Before you add program lines from this month's listing, you must first LOAD "HAM3". After it is loaded, LIST it. Then you are ready to start typing in the new material.

After you have completed typing in all the lines, save it under the name HAM4.

Using the New Program

LOAD the new program by typing LOAD "HAM4" and pressing ENTER. When the computer signals READY on the screen, type RUN and press ENTER.

The next thing you should see is the MAIN MENU for your new Ham System. It should show nine selections: ANTENNA DESIGN MATH, TRANSMISSION LINE MATH, OHM'S LAW, POWER FORMULAS, EFFICIENCY FORMULA, RADIO HORIZONS, OHMS TO RESISTOR COLORS, RESISTOR COLORS TO OHMS, and AIR COIL INDUCTANCE.

Clone users, put GWBASIC on a disk and add this handy batch file to start your system: At the DOS prompt type:

```
A> COPY CON HAM4.BAT
   ECHO OFF
   CLS
   GWBASIC HAM4
   (function key F6)
```

Press ENTER after each line.

C-64 Modifications

C-64 users remember the modifications listed in Part 1 of this series and the following:

Replace the listed lines as follows:

```
810 INPUT "FIRST BAND COLOR ";F$
811 INPUT "SECOND BAND COLOR";S$
812 INPUT "THIRD BAND COLOR ";T$
831 PRINT "THE  RESISTOR VALUE IS:"
832 PRINT F$S$T$" OHMS"
910 INPUT "DIAMETER IN INCHES: ";D
911 INPUT "LENGHT IN INCHES:   ";L
912 INPUT "NUMBER OF TURNS:    ";N
921 PRINT "INDUCTANCE = "FNA(L)" MICRO HENRYS"
```

HAM4 Listing

```
21 PRINT SPACE$(26);"8 - COLOR CODES TO OHMS"
22 PRINT SPACE$(26);"9 - AIR COIL INDUCTANCE"
39 IF M$ = "8" THEN 800
40 IF M$ = "9" THEN 900
800 CLEAR : CLS
801 PRINT SPACE$(25);"RESISTOR COLOR CODES"
802 PRINT SPACE$(20);"------------------------------"
803 PRINT : PRINT : PRINT
810 INPUT "ENTER THE COLOR OF THE FIRST BAND ";F$
811 INPUT "ENTER THE COLOR OF THE SECOND BAND";S$
812 INPUT "ENTER THE COLOR OF THE THIRD BAND ";T$
820 X$ = F$
821 GOSUB 850
822 F$ = A$
823 X$ = S$
824 GOSUB 850
825 S$ = A$
826 X$ = T$
827 GOSUB 870
828 T$ = A$
830 PRINT : PRINT : PRINT
831 PRINT "THE RESISTOR VALUE IS: "F$S$T$" OHMS"
832 PRINT
840 PRINT "N - TRY AGAIN"
841 PRINT "M - MAIN MENU"
842 M$ = INKEY$
843 IF M$ = "N" THEN 800
844 IF M$ = "M" THEN 10
845 GOTO 842
850 IF X$ = "BLACK" THEN A$ = "0"
851 IF X$ = "BROWN" THEN A$ = "1"
852 IF X$ = "RED" THEN A$ = "2"
853 IF X$ = "ORANGE" THEN A$ = "3"
854 IF X$ = "YELLOW" THEN A$ = "4"
855 IF X$ = "GREEN" THEN A$ = "5"
856 IF X$ = "BLUE" THEN A$ = "6"
857 IF X$ = "VIOLET" THEN A$ = "7"
858 IF X$ = "GRAY" THEN A$ = "8"
859 IF X$ = "WHITE" THEN A$ = "9"
860 RETURN
870 IF X$ = "BLACK" THEN A$ = ""
871 IF X$ = "BROWN" THEN A$ = "0"
872 IF X$ = "RED" THEN A$ = "00"
873 IF X$ = "ORANGE" THEN A$ = ",000"
```

by Bill Brown WB8ELK

The TAPR METCON-1 Kit

Tucson Amateur Packet Radio (TAPR)
P.O. Box 12925
Tucson AZ 85732-2925
Tel. (602) 749-9479
FAX: (602) 749-5636
Price Class: Main Board, $85;
V-to-F Converter, $25; Temperature Board, $30.

Add telemetry and control to your packet station.

How would you like to have the ability to read sensors or control circuitry from a remote location via packet radio? Thanks to a new kit from the folks at TAPR (Tucson Amateur Packet Radio), it's now easy to take full advantage of advanced packet control.

Packet Telemetry

The METCON-1 kit (TeleMETry CONtrol) is a versatile telemetry/control unit that uses a serial port for communications. You can send commands to the METCON-1 board via a computer serial port, telephone modem or a packet TNC.

The METCON-1 board simply hooks up between a packet TNC's serial port and the circuits you want to control or sense.

One of the most obvious uses for the METCON-1 board would be in a remote repeater installation. Useful information such as building temperature, amplifier temperature, backup battery voltage, and AC power status can be easily sent back at fixed intervals (or upon a connect request). You can also use the METCON-1 to turn on transmitters, lights, amplifiers, antennas, and just about anything else that can be activated by a relay.

The METCON-1 board also looks at the status of binary inputs. Whenever it detects a change in one of these lines it automatically sends out a status message. I use this feature as an intruder alert in my installation. I hooked up the METCON-1 to a micro-switch that closes whenever anyone opens the hamshack door! Since the METCON-1 has a built-in clock, it actually sends me a timestamp of the event (I know exactly when the door was opened!). Not only can the unit detect "On/Off" transitions on its six inputs, it can measure frequency as well (0 to 10 kHz).

Kit Assembly

The kit comes complete with all components as well as a high quality doubled-sided PC board. An optional voltage-to-frequency interface board is also available. Component placement is well-marked and silk-screened onto each board to make assembly a real breeze.

Construction was quite straightforward and went easily. The assembly instructions were excellent, with every step spelled out in detail. The checklist format helps ensure that you don't miss a step or component. Since this is a double-sided board with plated through-holes, it's important to take care in assembly. Removing components from a double-sided board could be difficult.

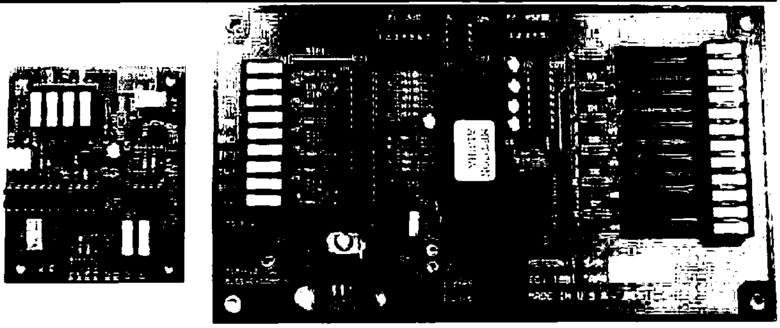

Photo. The assembled TAPR METCON-1 telemetry and control unit. The smaller PC board to the left is the optional V-to-F interface board.

Sockets are provided for all ICs. I particularly like the connectors used for interfacing to the outside world. You just slide a wire into the hole and hold it in place with a snap lever (no soldering!). This scheme also makes it easy to quickly change your external wiring (particularly useful when you're at a remote repeater site).

Installation

The METCON-1 board communicates via its serial port. You can use a telephone modem, computer serial port, or a packet TNC to send commands and receive data. In a typical packet hookup, you just connect the METCON-1 lo your packet TNC's serial port and hook up the items you want to control to any of the six onboard relays. The six inputs to the METCON board can be used as "On/Off" detectors. These inputs can also function as a frequency counter which allows use of a voltage-to-frequency interface board.

The V-to-F Interface

Through the use of the optional V-to-F (voltage to frequency) board, sensors can be interfaced to the METCON-1. Any device that outputs a voltage between 0 to 10 volts (when configured for low input range) or 0 to 100 volts (high input range) can be measured. You can also configure the V-to-F board to function as a temperature sensor. Each V-to-F board hooks up to one of the input ports of the METCON-1 board. You just read out the frequency on the main memory map output. In the case of voltage, just divide the frequency by 10. To get temperature readings you must divide by 10 and then subtract 100.

The voltage-to-frequency scheme has some intriguing advantages over traditional A-to-D (analog to digital) converters. Since the voltage level is converted to a frequency directly at the source, it doesn't suffer from voltage drops or noise when using long wire leads from a sensor. The drawback to this method is that it takes a full second for each sample (each channel). For most applications this is more than sufficient. However, you can plug an optional ADC (analog-to-digital converter) directly into the METCON board if you desire. The ADC board is a future option that is not currently available.

Operation

Commands to the METCON-1 are performed in individually addressed bits or bytes. Each area of the METCON's memory contain specific locations for input and output status, frequency counter output, system configuration and A/D conversions. You can display a memory location, write to it or reset it. All commands are preceded by an "=" sign and a METCON station address (in case you have more than one METCON board in your system—The default address is "A").

CIRCLE 153 ON READER SERVICE CARD

METCON-1 KIT *Continued from page 34*

For example: The memory address for the six relay outputs is location number 05. To turn on relay 1, you send the command "=AS050". The "S" is the set command, the "05" is the memory address, and the "0" is the relay number. To turn off the relay, you just need to send the clear command: "=AC050". If you want to look at the memory location, the command is "=AD050" ("D" for display). That's really all there is to it. If you want to turn on or off several relays, you can send a byte write command that sets all of the control bits in one operation. Example: "=AWY050F" turns on relays 0,1,2 and 3 simultaneously, since the "0F" address sets the lower 4 bits "On".

For repeater or remote base control, the password feature adds a level of security. You can set up certain portions of memory as restricted. In this mode, you need to logon to the METCON-1 with a password in order to perform control operations.

Impressions

I have the METCON-1 installed in the W2NSD/1 hamshack. It's hooked up to a 10 meter CW beacon transmitter, a low-power 2m FM transmitter, an ATV transmitter, a TV camera, and lights. Whenever I want a signal source on ATV, 10 or 2 meters, I just connect up on packet and have a blast turning the equipment on and off remotely. I use the inputs to measure the shack temperature as well as to indicate when the shack door is opened.

Sure, I could've done part of this with a touchtone decoder, but the METCON-1 system allows me to control things error-free, as well as provide real-time telemetry.

The review unit was the preliminary version of METCON-1 (Alpha Test). I found the assembly instructions to be very complete and easy to follow. For those of you with the preliminary manual, you may have to dig around a bit to understand how all of the commands work, however. Once you figure out how the memory addresses are configured, you'll be well on your way to controlling things.

To some extent, you do have to decipher the values presented to you in the memory map. The METCON-1 board won't come right out and tell you "The Temperature is:" or "Battery voltage =." Once you have figured out the memory map, you can easily read your system's status.

For those hardware and software hackers out there, there is room to add a substantial amount of I/O capability to this system. There is provision for a fast upload and download of the system memory. You could write a program to display this information in graphics form for a really spectacular display in an easy-to-read format.

The METCON-1 system is a powerful and economical tool for anyone considering remote control applications. You'll probably wonder how you got along without it! 73

When you want to use HAM4, just place the disk into the drive and type "HAM4", then press ENTER. GWBASIC will execute, and HAM4 will load and run. The bottom light bar will be extinguished, leaving a very professional appearing menu.

Comments

The system has grown over the past few months. I sincerely hope you find it as useful as I found it fun to write. If you would like for the system to grow more, write me. I would consider doing an update from time to time.

For readers not wishing to type in the many lines of program code that have appeared in this series, I will make copies. The cost is $5, which includes the disk, copying, and shipping. SPECIFY CLONE OR C-64. Write to me at the address below. Also, each module as well as the complete program can be downloaded from the *73* BBS at (603) 525-4438. Look for the listings under the *73mag* SIG. 73

You may write Bill Clarke WA4BLC at RD #2 Box 455-A, Altamont NY 12009. Please enclose an SASE for a reply.

Universal CAT Interface

Control your rig with your computer!

by Art Harding K5YEF

Many of us got excited in the early '80s when microprocessor radios appeared on the market. This heralded the beginning of the patching together—"interfacing"—of personal computers and amateur radio equipment. This offered the promise of menu-driven radio operation, vastly increased and enhanced memory, complete rig status display on the computer monitor—and the imagination went wild.

But there is a hitch—many computers and microprocessor rigs can't "talk" to each other directly. Most rigs want to converse with Transistor-Transistor Logic (TTL) bit transfer levels between 0 and +5 volts, but most of our computers demand that the digital dialogue go along RS-232C levels, which are from −12 to +12 volts. Commercial interface units mean more bucks, and, well, someday maybe we'll get around to creating one. And so for many of us, the rig and the computer remained separate. *[Ed. Note: Many modern rigs have a computer control port. They are known as Computer Accessed Transceivers (CAT)].*

Birth Of The Project

For me, "someday" finally came. After operating Yaesu's FT-980 HF radio for several years, the itch for CPU control got too strong, and I set forth to design and build the interface.

What follows is a solution, not just for the IBM and FT-980, but for any computer with an RS-232 serial port and a CPU radio with a TTL port. You can keep it simple on a breadboard or you can build up a permanent black box for full-time operation.

Digital Transfer

Figure 1a shows a random RS-232 waveform coming from a computer's serial port. The waveform needs to be converted to TTL levels for the radio. Note that the signal is inverted at the TTL port from whence it came. It could have been left in phase, and the software signals programmed to make 1's into 0's and vice versa. But this step can be eliminated by the hardware, and that's the course I took, preferring to keep the software simple.

In Figure 1b, the reverse takes place. Many radios send back command echoes, confirmation and status signals, for the computer to process. Again, an inverting action is desirable.

Refer to Figure 2, a portion of the FT-980 schematic for the CPU section. Note that any interface circuit must deliver its output data stream into a load of at least 165 ohms (330/2)! However, the serial data stream out of the radio is a stiff NPN switch, a nice signal to work with.

I could not get my hands on all microprocessor-controlled radios, of course, but on-the-air surveys indicated that the FT-980 radio is a good test bed for circuit development for other CPU radios on today's market. So, even if you're not dealing with this specific configuration, it's worth it to read on!

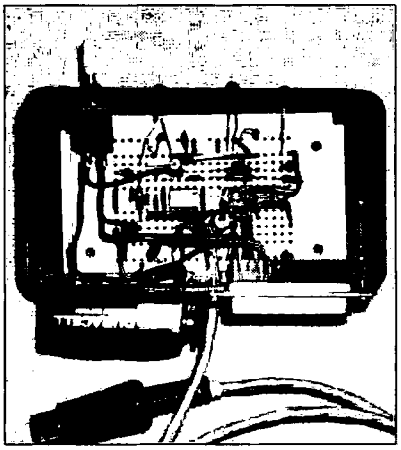

Photo A. The components were mounted on an Experimenters Socket which fits neatly into a case available from Radio Shack (no soldering!).

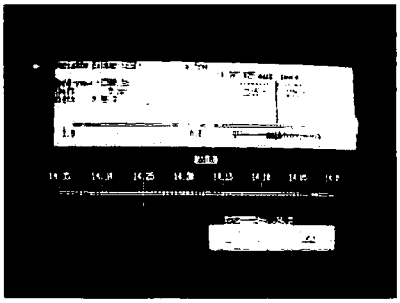

Photo B. The CAT980 program display. This full-featured program is available from the author as shareware (see the Parts List for details).

A Simple Interface Circuit

The result is the circuit shown in Figure 3. An old friend, U1, an LM324 quad op amp, does the job with two of its amps still unused. U1a acts as an inverting, saturating differential voltage comparator with a Schmitt trigger personality, and U1b does the same thing in the reverse direction.

They are not identical circuits, however. U1b drives the TTL input to the radio, the low 165 ohm load mentioned above. The idea is to only draw serious power when the negative going or "ground" level pulses occur. As the RS-232 pulse from the computer goes positive on pin 2 of the input connector, the output is driven negative through R7 and D2. D3 clamps the pulse so that it just stays above ground level, yet low enough to be read as a zero TTL signal. The negative input pulses, or static state (no commands being sent to the radio), draw minimum current from the power source.

U1a doesn't have quite the demand on it to perform its function of converting TTL signals from the radio to the computer. R1 was originally 18k during software development, and that value seems to work fine for IBM and compatibles. When I used a laptop, I found more drive was needed. I settled on a value of 3.3k, which has worked with all computers used to date.

Figure 3 shows you all that you will need to breadboard a no-frills interface in order to try some of your programming ideas. You can easily put it all on a Radio Shack Experimenter Socket (RS 276-175), and use cable ties to hold down the interconnecting cables to the breadboard. *[Ed. Note: The Radio Shack prototype board is an excellent way to quickly build circuits without any soldering.]* I used this circuit for eight months during

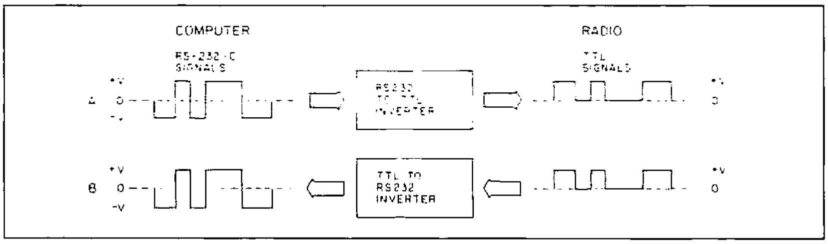

Figure 1. Interface signal path.

software development, with a power source of two 9 V batteries, which I switched in and out as needed.

A Deluxe Interface

When the last line of code was written (though we who write code know that no such time ever comes!) and a couple of operating months went by, I wanted a permanent black box with only one battery to mess with. Or maybe no battery at all! Figure 4 shows the results. In the final version, I added a number of refinements, which we'll examine.

It seemed most desirable to have a visual handle on the operation of the interface, some lights that showed what was going on. When writing software and dealing with a computer port, the nagging question often is: Did that command go out the port like it was supposed to? By replacing D2 in Figure 3 with an LED, not only is this question put to rest, but the same LED also signals the transition of the command to a TTL level. When serial positive-going pulses output the computer port, D2 will light up as U1B, making the signal negative-ground going.

The addition of R10 and LED D4 serves the same function for inputs to the computer after TTL to RS-232 transition. A new diode, D5, blocks negative RS-232 levels from the computer, yet passes the all-important positive-going levels.

I have added a new circuit consisting of Q1, D6, D7, R5, and R9, to control a radio key line with a computer. I chose the RTS line in the computer port to key the radio. A positive signal on this line saturates Q1 and grounds pin 4 of the 6-pin DIN radio connector that keys the rig. Note that D6 is also an LED, so the operator has a visual on-the-air light. This is optional, but the odds are you're also going to want to key your radio from the keyboard. You may wish to omit this portion of the interface if you plan to key the radio as you normally do, such as for VOX operation.

The last enhancement, shown in Figure 4, is a negative voltage supply for the interface, so that you need only one battery or positive supply voltage. This simple circuit has been around in various forms over the years. U2, a 555 timer, oscillates around 1 to 2 kHz at the output of pin 3 on the chip. The network consisting of D8, D9 C3, and C4 comprises a full-wave rectifier circuit to take the place of an external negative supply. You may wish to eliminate the battery and use a 9 V supply, perhaps by bringing in a +9 V to +12 V line from the radio itself.

Table 1. 6-Pin Signal Assignments

6-Pin Din	Signal
1	GND
2	TTL signal from radio
3	TTL signal to radio
4	Key line

An on/off switch completes the interface. It seemed wise to use one section of the switch to disconnect the key line from the interface when it was not in use. If you do bring in the power from the radio, you may wish to eliminate the power switch.

Construction of the Interface

The parts list contains the few components you will need to get the simple or permanent interface operational. Both of them use the Radio Shack Experimenter Socket, which fits snugly down into the Radio Shack Deluxe Project Case.

Well, it almost fits. It's certainly tight enough; no hardware is required to keep it in place. I chose to view this as a blessing, not an "Oh no!" If you wish, you can easily drill the plastic case to mount the LEDs and the power switch. I used the faithful nibbler tool to eat out a three-sided hole in the back panel to mount the RS-232 male connector. The cable from the radio was brought in through a back

An EXE program in PASCAL, available on CompuServe, or send $5.00 ($20 for full registration) to Art Harding K5YEF, P.O. BOX 861719, Piano TX 75074. Specify 5¼" or 3½" disk.
NOTE: The GW-BASIC program CAT_SEED shown in this article (Figure 5) is included on this disk. The CAT_SEED program is also available from the *73* BBS under the *73MAG* SIG at (603) 525-4438.

panel hole and held in place on the circuit side with a cable tie.

I found a couple of small capacitors at a street sale to use as C3 and C4. Radio Shack equivalents are listed in the parts list, but I suspect their physical size will not be as pleasing to the eye. That's why they make tops to the boxes.

When all was said and done, there was still room on the back panel to mount a 9 V battery with a rubber band passing through two small holes, then tied off.

The 6-pin DIN connector at the end of the cable is shown for operation of an FT-980 only. You may be talking to another radio, so you will have other pin connections and connector. Check your manual and use Table 1 to wire your configuration. The RS-232 connections are the same for all computers, even non-IBMs. Check your serial port manual to make sure this isn't a lie!

Operation

Operation is straightforward. Except for the on/off power switch, it can be unattended. As your program commands the radio, LED D2 will follow the activity. If your radio responds with echo or status information, as does the FT-980, LED D4 will likewise follow the TTL to RS-232 response. LED D6 lights when the radio is keyed either by the computer or by the radio itself.

Most radios require a 4800 baud rate for computer-to-radio communication. Since we're dealing with a saturated amplifier configuration, the baud rate is of no consequence if it stays within reason. "Reason," of course, is some high baud rate where the circuit frequency response can no longer keep up with the transistion time. I don't know of any radio presently available which should cause concern.

One final note about operating: RFI. When you look at the schematics, you can see that I used no bypass capacitors. You may wish to include 0.001 µF caps across all input and output lines. That's fine, but there's a better solution to computer-generated RFI: toriod traps, like Radio Shack's toroid choke RS 273-104, or those offered by MFJ and other manufacturers. No installation is complete at K5YEF without one of these somewhere in the line of the new gadget. I did a four-turn choke using one of these between the interface and the FT-980 without any noticeable increase in birdies when it's on line.

Testing the Interface

Testing is done with the interface not connected to the computer or the radio, but with the interface battery installed. Use a second 9 V battery to connect the negative terminal to pin 7 of the RS-232 interface connector (ground). Be sure to use a 10k resistor in series with the testing battery in the following steps!

Turn the interface on and touch pin 2 of the RS-232 interface connector. LED D2 should light. If you've included the key line circuit, then touch pin 4, and LED D6 should light.

Now disconnect the test battery; you're through with it. Run a wire to pin 7 of the RS-232 interface connector, and short it to pin 2 on the 6-pin DIN connector. LED D4 should light. Be sure to see Table 1 if you are not using a 6-pin DIN for an FT-980 for this test point.

That's it, you're ready. Turn off the interface and put it in line between your radio and computer.

An Alternative

Most of the parts for the simple and deluxe versions of the interface are available from your neighborhood Radio Shack store. However, if you can obtain a MAX232 IC, a smaller version of the CAT interface can be built. M.G.D. Vermeulen ZS1HQ came up with this design which also takes power directly from the FT-980 accessory socket (no battery needed). If you have difficulty finding the MAX232, you can replace it with a Harris ICL232. The ICL232 is available from Digi-Key, P.O. Box 677, Thief River Falls MN 56701-0677. Phone (800) 344-4539. See Figure 5 for this circuit.

Just the Beginning

This project is not an end unto itself; it is really the beginning. The CAT interface is a door to all the control ideas you have running around inside your head when you bought your radio. It's simple to build, and you can begin experimenting with software (don't let anybody tell you it can't be done in BASIC—they haven't proven that to me yet!). Spread spectrum, maybe?

Design Your Own CAT Program

After you do the simple hardware tests on the Universal CAT Interface, you'll be itching to try your system in the CAT mode. Presented here is a GW-BASIC (Version 3.2) program which I believe you can use to adapt to any CAT equipped radio. "Those are big words, stranger." I know, I know. The big problem is a lack of a CAT standard. If there are two radios with the exact same I/O command set I am unaware of them! I would urge the radio industry to get together and agree on a standard command set for CAT control. But you have to start somewhere and I would like to plant this program which I have put into the Public Domain into your schedule and let you run with it.

It's not going to be easy, but it is relatively simple. You'll understand what I mean if you'll commit to the attempt, and if you will just maintain an I-CAN-DO-IT attitude, take your time and keep trying, you will eventually get the desired results. And I can't describe what a great feeling it is to see the radio respond to your keyboard.

You lucky FT-980 owners can use the program as is. It will come up and capture the radio and display all 148 status bytes from the radio. It will settle on 20 meters, USB, 14.250.000, picked because that is the example in the YAESU manual. Hit <ENTER> and the radio switches to AM and WWV on 10 MHz. Hit <ENTER> again and the radio switches to 10 meter FM and begins a frequency scan from 29.500 to 29.690 ad infinitum. You can interrupt the scan or resume it by hitting any key at any time. The screen displays the frequency too. <F1> exits the program at any point you desire.

The one quirk 980 owners will discover is that it will require two tries to capture the radio the first time. Run the program and after a few seconds do a Ctrl-Break. Then run it again. From then on (unless you turn the radio off) it will run on the first try. Sure, you can add a fix. I had to add one to my Pascal version, but it is beyond the scope of this exercise.

OK, so what if you own a radio other than the FT-980? This program will be a good solid starting point. Oh yes, it will require some knowledge of BASIC, patience and study, but the trek will be worth it. The program has the two main ingredients necessary for CAT activity: a way to output commands and a way to capture data from the radio.

First study your manual and become familiar with the sequencing of events that your radio requires. The FT-980, for example, requires the following:

1. Send a command to the radio.
2. Receive an echo of the command from the radio.
3. Have your software compare the command against the echo. If they are the same, then perform the next step, #4. If not, then start over again at step #1.
4. Send OK-TO-EXECUTE command to the radio.
5. Receive a status stream from the radio to update the changes it just made.

WOW! Well the fact is the FT-980 is one of the more complicated CAT radios ever put on the market. (I give that a plus, not a minus!) Unlike the sequence listed above, your radio may only need to receive a command to change mode or frequency. It may or may not "talk" back to your computer at all. So at this point we can begin to trim down the CAT_SEED program to customize it to your radio. In the following steps when you're advised to "eliminate the following lines" you might wish to simply REMark them out—just in case.

Tailor the Program For Your Particular Radio

1. Eliminate line 2030; it surely just applies to the FT-980.

2. If your radio isn't captured during a CAT session, that is, if it only responds to commands but the front panel controls re-

SCARED OF THE CODE?
IT'S A SNAP WITH THE ELEGANTLY SIMPLE MORSE TUTOR ADVANCED EDITION FOR BEGINNERS TO EXPERTS—AND BEYOND
Morse Code teaching software from GGTE is the most popular in the world—and for good reason. You'll learn quickest with the most modern teaching methods—including Farnsworth or standard code, on-screen flashcards, random characters, words and billions of conversations guaranteed to contain every required character every time—in 12 easy lessons.
Sneak through bothersome plateaus in one tenth of a word per minute steps. Or, create your own drills and play them, print them and save them to disk. Import, analyze and convert text to code for additional drills.
Get the software the ARRL sells and uses to create their practice and test tapes. Morse Tutor Advanced Edition is approved for VE exams at all levels. Morse Tutor is great—Morse Tutor Advanced Edition is even better—and it's in user selectable color. Order yours today.
For all MS-DOS computers (including laptops).
Available at dealers, thru *QST* or *73* or send $29.95 + $2 S&H (CA residents add 6% tax) to:

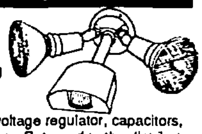
INFRARED SECURITY LIGHT (AS-IS)



Experiment with infrared sensors with these outdoor security lights. Contain lots of interesting components, and IR detector, photoresistor, relay,transformer, IC's, voltage regulator, capacitors, trimpots and other goodies. Returned to the distributor for variety of reasons, we've found that most of them work to some extent. We don't want to test them and would prefer to sell them "as-is" at a greatly reduced price. Mounts to any standard electrical junction box. Infrared sensor detects movement up to 65 feet and turns on lights. Sensor can be adjusted for sensitivity and duration of lighting. The position of the sockets and the infrared sensor can be easily adjusted. Will handle two 150 watt PAR 38 lamps. Suitable for wet locations. Bulbs not included.CAT# IL-101 $7.50 each

HALL EFFECT LATCH

Sprague # UGN3075LT
Operates on 4.5 - 24 Volts
Can sink 10 ma. With suitable output pull up, can be used directly with bipolar or CMOS logic circuits. Especially suited for electronic commutation in brushless D.C. motors using multiple ring magnets. Very tiny surface mount package 0.175" X 0.09"X 0.06" thick.
CAT # HESW-5 2 for $1.00
100 for $45.00 Large quantities available

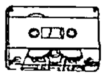
FLASH ASSEMBLY

This NEW compact flash assembly comes from a U.S. manufacturer of cameras. Unit operates on 3 Vdc and measures 2 1/2" X 1 1/4". Ideal for use as a strobe, warning light or attention getter. Complete with instruction on how to wire.
CAT# FSH-1 $3.75 each 10 for $35.00

ULTRASONIC CERAMIC MICROPHONE/TRANSDUCER

Panasonic (Matsushita) # EFR RCBK40K54
An ultrasonic microphone consisting of a bimorph type piezoelectric ceramic vibrator. Ideal for burglar alarms, auto door openers, flow rate detectors and remote control systems. Nom. Freq. 40 kHz. Max input volts: 20 Volts. 15/16" diameter X 3/8" high. 5/8" long leads.
CAT# UST-1 $1.00 each

HIGHEST QUALITY METAL C-60 CASSETTES (Erased)



Premium quality metal tape in C-60 cassettes (30 min. per side). One of the finest "brand-name" tapes on the market, in durable, clear plastic transport mechanisms. Recorded and bulk erased, the record-protect tabs have been removed and therefore, need to be taped over to re-record. Audiophiles will appreciate the wide dynamic range of this tape. If your cassette deck has a "metal" setting you will hear the difference. A real bargain!
CAT# C-60M $1.25 each • 10 for $10.00

```

main operational between commands, then you should eliminate the following lines: 90, 1070 and 2020.

3. If your radio does NOT echo the commands you send it, you should eliminate the following lines: 1020, 6050 thru 6080.

4. If your radio does NOT have an OK or EXECUTE-THE-COMMAND type command you should eliminate the following lines: 100, 1060, 5030, 7000 thru 7030.

5. Does your radio send back any information like a status stream or some sort of acknowledgement that the command took effect? If your radio does NOT send back anything, you should eliminate lines: 1030, 1080, 2110, 3030, 5040, 6030, 8000 thru 8040, 9100 thru 9150, and 10000 thru 10020. You may eliminate the variable R and all references to R.

Now the next thing you want to do is study the INITIALIZATION portion of the program, lines 1000 thru 1130. Whatever brand of radio you own it's going to need a command buffer defined in line 1040. The one in our seed program is presently 5 bytes. If you need less or more, change it accordingly. A 6 byte command would appear as CMD$="   " (that was six spaces) or perhaps even better, use DIM CMD$(6).

Other FT-980 commands are part of the initialization subroutine such as the command for VFO, USB, etc. Simply substitute commands required by your radio. If there is no substitution in some cases then eliminate that particular one and any other reference to it you may find in the program. After you get this program working then you can add the complete command set.

If your radio does receive status then be sure line 1030 is configured correctly. It is now 148 bytes, the maximum number of bytes the FT-980 radio will send to the computer at any one time. You should make it as large as the number of bytes your manual shows is the maximum you may receive from your radio.

What's left? One of the most important things: setting up the COM port for your particular needs. Let's look at line 9010:
OPEN "COM1:4800,N,8,2,RS,CS10,DS, BIN" FOR RANDOM AS #1.

Check your GW-BASIC manual and your radio manual; make sure these parameters are correct. More than one program I've seen was "bad" because the author used one stop bit. Why not? The rest of the world uses one stop bit—but not the FT-980 PROM. It demands two! So make sure all is OK. The parameter 10 associated with CS above will most likely have to drop to zero if you are using a slow computer and a value higher than 10 for faster machines. I have tested the program at 4.77 MHz on a laptop (CS0) and at 16 MHz on a 386 machine (CS10). One other comment on the port: you may also use COM2 instead of COM1. If you wish to do this be sure to change all COM references throughout the program.

As you work with the program I recommend that you just concentrate on getting the computer/radio dialog going with consistent results. Then you can open up your imagination and add the bells and whistles. Today, my CAT980 program (available as shareware) has some pretty fancy displays, like filter plots, analog dials and user menus for instant deployment. Even a log is included which automatically records all the radio parameters of the moment. But there was a time when the program just sat there and did nothing.

So with that in mind here is one last thought: share your basic ideas with other hams. Write an article or submit a listing to the technical correspondence sections of our magazines. Put your program on BBS's like CompuServe. And if you feel like you've got a program for the big leagues, then enter the world of Shareware. The real fun, and I believe this strongly, is still out there.

There's a barely scratched world of controlled excitement waiting to take shape, and like a lot of things in ham radio, we can have more fun if we keep each other informed. These pages and this interface are a good place to start. ■

73 Review

by Dick Goodman WA3USG

The Kantronics KTU Telemetry Unit with Weathernode EPROM

Remote weather observations via packet!

Kantronics
1202 E. 23rd St.
Lawrence KS 66046
(913) 842-7745
Price Class: KTU—$300
Options: Anemometer—$110
Rain gauge—$ 90

Packet radio is the most rapidly growing and diverse mode in the history of amateur radio! In the early 1980s, the "Packet Revolution" was started by dedicated groups of amateurs in both Canada and the USA. These amateurs stimulated packet growth by setting standards and protocols, offering the first TNCs in kit form at a price affordable to amateurs and, perhaps most importantly, providing much needed information on this fledgling mode. As the years progressed, packet technology accelerated at an exponential rate.

Packet research and development, until recently, has been in the direction of increasing pure communications capabilities. There is another aspect of packet that is finally receiving attention, and that is data acquisition and control.

While communications, BBS usage, message handling and related applications will always be the mainstay of packet, automatic collection and forwarding of data will become widespread in the upcoming years. Wouldn't it be nice to have access to weather conditions at your club site via packet? Parameters such as temperature, wind speed, direction, and even rainfall could be valuable prior to starting an antenna work party. What about the condition of your club's repeater? Knowing the repeater's PA stage heat-sink temperature, PA current, line and Vcc voltages, and AGC voltage, could be most helpful to control operators. How about remote control of equipment? The capability to power down, energize, or reset various devices might be beneficial. Again, as with the "communications" aspect of packet, experimenters have been doing this for years, but until recently there has been no turnkey system to make this possible for the less technically orientated.

Data Acquisition and Control with the KTU

The Kantronics Telemetry Unit (KTU) with the Weathernode EPROM makes these functions possible. The KTU is a small device, 1.75" x 6" x 8", designated as Data Terminal Equipment (DTE). It simply plugs into your existing TNC where your computer (orterminal) would normally be connected. Your computer is then plugged into the rear of the KTU.

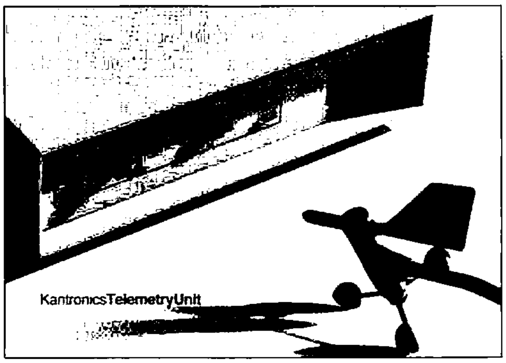

Photo. The Kantronics KTU Telemetry Unit.

The power requirements are 11-20 VDC at 45 mA or, in the "Low Power" mode, 11-28 VDC at 30 mA. The KTU front panel is laid out quite simply. There is a power switch and a power indicator LED. Next to that, a "Telemetry/Local" switch and two LEDs show which position that switch is in. Finally there is a "Bypass" switch and companion indicator LED.

The KTU rear panel consists of a standard DB-25 connector for your computer or terminal, a modular style connector that connects to your TNC (cable and mating connector are supplied), and an 8-pin external sensor connector (cable and mating connector are supplied). Note that normal packet operation is not affected by the KTU; pressing the "Bypass" switch connects the terminal to the TNC and takes the KTU out of line.

Since the KTU includes the Weathernode EPROM, I got the optional anemometer/wind direction indicator. This unit, which includes mounting hardware, is of high quality plastic construction and requires minimal assembly. It's not necessary to calibrate the wind speed portion of the instrument; the wind direction sensor is calibrated with just a compass. Ensure that the instrument is mounted outside as high as possible, and away from obstructions, in order to obtain accurate readings. Both this unit and the external temperature sensor (included with the KTU) connect to the 8-pin connector on the rear of the KTU.

The serial cable from the computer should be connected to the DB-25 connector on the rear of the KTU, and the TNC connected to the KTU via the modular cable provided. These levels may be either RS-232 or TTL, set by internal jumpers in the KTU. If any cables have to be made up, pinouts for all connectors are adequately detailed in the documentation. Once these connections are made, the KTU may be powered up and initialized for operation with your TNC.

Set-Up and Configuration

Set your communications terminal for 8 data bits and the baud rate to match the TNC to the computer baud rate. Set the KTU "Bypass" and "Telemetry/Local" switches to "OUT," then apply power. The KTU will sign on your terminal with its autobaud routine and sign-on message. You will be prompted to enter the date and time.

Once this is completed, operational parameters may be set. These parameters are similar to those used in your TNC (e.g.: abaud, flow, echo, parity, xflow, etc.). The KTU will be optimized in this process to communicate with your TNC. Once the KTU is initialized, some TNC parameters will probably have to be modified. Those options are adequately explained in the documentation.

Once these steps are completed, the KTU is ready for programming. Programming the KTU instructs the unit on how often to sample the external sensors, how to display the results (metric/USA), how many entries to send in response to a data command, and how many entries may be stored in the KTU's inter-

nal memory. Sensors may be sampled and displayed in a range of time from seconds to months. This versatility is quite impressive! The documentation goes into considerable detail on proper syntax and procedures. The KTU may be configured to operate with a variety of TNCs and is compatible with virtually all packet LAN configurations. The KTU may be programmed in a local mode directly from the terminal connected to it, or from over the air. Over-the-air programming requires entry of a password and other unique security constraints.

Using the KTU to obtain weather data is quite simple after reading the user instructions. These instructions are formatted to allow the KTU owner to simply photocopy both sides of one page in the KTU system manual and pass it along to potential users.

On-Line with the KTU

The TNC used for this review was the Kantronics KPC-4. By issuing a connect request to my station a user receives the normal "Connected to" response followed by a "wxn:" prompt. At this point the KTU may be queried for weather data, or programmed by the "Sysop." By simply typing a "D" for (D)ata, the KTU will display the last reading of wind speed, direction, external temperature, and internal KTU PC board temperature (see Figure 1). If the optional rain gauge sensor is installed, this data will also be presented. By entering the correct command, USA or Metric units may be specified. The data command may be modified to request virtually any number of entries from those stored internally.

An example of the data command syntax is: "Data TF 3 WS 5 WD 2"—This would display three readings of external temperature, five readings of wind speed, and two readings of wind direction. Entering the command "PR," displays how the data is being stored. An example of a reply to a "PR" request might be:

"PROGRAM R10M TP TF A15S WD WS
7813 Samples 1 Day 08:00:00."

This response to the "PR" command would tell the user that the internal and external temperatures are being sampled and recorded once every 10 minutes and the wind speed and direction are being averaged and recorded once every 15 seconds. The second line displays the capacity of the KTU's internal memory buffers in this data configuration. In this case, the buffers will store one day and eight hours of data before the earliest information is overwritten. Knowing this, the user can request data in a format useful to their application. If the outdoor temperature is being saved every 10 minutes, the user may not want every reading. Entering a data command of "Data TF 20 3" would display every third reading of temperature for 20 readings (or 20 readings in half-hour steps). All data read with the "Data" command is date and time stamped by the KTU (see Figure 2).

As you can see, by judicious use of programming, the Sysop can save data over long periods of time by keeping the sampling rate low. This would be efficient for day-to-day weather data collection. However, during unique weather phenomenon, the sampling rate may be increased on all sensors to allow instantaneous response to changing temperatures, wind speed, direction, and rainfall. This would be excellent for recording the passage of storm fronts and the like. With this simple, yet versatile data gathering language, the user may request data from any sensor as little or as often as desired.

Other Capabilities

The KTU will support up to seven sensors attached to the rear panel inputs. Each of these sensors accepts a 0–5 VDC input. These inputs are those that are presently being accessed by the Weathernode EPROM. Depending on how the KTU is configured (with internal jumpers), certain rear panel connections may also be programmed to output digital levels (0 and 5 VDC). These connections may also be commanded to generate pulses with the frequency being determined by the user via the "FØ" or "F1" command. This capability would be excellent for controlling remote devices. All this is explained in the KTU system manual. This sophisticated data acquisition mode may not be used in conjunction with the Weathernode, since the weather sensors use all rear panel inputs.

Observations

The KTU did absolutely everything that it was advertised to do. I was impressed with the ease of assembly of the weather instruments and their quality. The anemometer tracks what my existing Heathkit unit displays to within about five percent. The wind direction indicator provides resolution down to single degree units and displays this data in both heading and compass rose notation (e.g.: N, NE, ENE, etc.). The external temperature sensor comes with about 50 feet of connecting cable, as does the anemometer. It is also possible to add additional cable without affecting the calibration of the unit.

The KTU itself is small and has minimal power requirements. I thought that since the internal temperature sensor was located inside the KTU it would indicate considerably higher temperatures than ambient due to component heating. This is not the case, due to the low current requirement of the KTU. The internal temperature displayed by the KTU is within a degree or two of the actual air temperature.

Finally, it took me no more then one hour to get everything fully operational (and that's from the time I opened the two boxes that the units were shipped in). The Kantronics firmware in the KTU operated flawlessly. The flexibility in the way weather data may be captured and presented should meet the requirements of the most demanding amateur and professional meteorologists. The only room for improvement I could suggest is that memory slots be made available for high and low temperatures and peak wind speeds. This data may be derived from the stored weather data, however.

With the development of additional EPROMS, telemetry and data acquisition from a wide variety of applications will be possible. Kantronics has effectively entered a new era in packet technology with this innovative product! ■

EVERY ISSUE of *73* on microfiche!

The entire run of *73* from October, 1960 through last year is available.

You can have access to the treasures of *73* without several hundred pounds of bulky back issues. Our 24x fiche have 98 pages each and will fit in a card file on your desk.

We offer a battery operated hand held viewer for $75, and a desk model for $220. Libraries have these readers.

The collection of over 600 microfiche, is available as an entire set, (no partial sets) for $250 plus $5 for shipping (USA). Annual updates available for $10.

Your full satisfaction is guaranteed or your money back. Visa/MC accepted.

Hope for Monolingual Hams

If you really want to communicate!

by David Cowhig WA1LBP

Most hams on or orbiting this planet do not speak English as their first language. *The Radio Amateur's Conversation Guide*, written by Jukka OH1BR and Miika OH2BAD Heikinheimo, with the help of ham native speakers, teaches monolingual hams how to get their tongues into acceptable shape for foreign ears. The second edition, published in 1985, includes English, German, French, Italian, Spanish, Portuguese, Russian (in Cyrillic and phonetic script), and Japanese (romanized). Hour-long cassette tapes made by ham native speakers cover these languages, plus Swedish and Finnish.

Supplements to the *Guide* introduce you to Finnish, Danish, Dutch and Serbo-Croatian. Phonetic guides and number lists are followed by 50 pages of phrases in each of the eight languages of the *Guide*. In the 30-page multilingual glossary at the back of the book, you can look up the equivalent of English words commonly used by hams in seven other languages.

The phrases give you all you need to conduct a very basic QSO (contact), describe your equipment, complain about the other guy's splatter, inquire into the other operator's marital status (an important question for international radio romances), and ask for a QSL card. Next time a Japanese station QRMs (interferes with) your long rag-chew on 160 meters, you can tell her "Shuhatsu-o tsukatteimasu!" If the offending OM (male ham) is in Moscow, you might say, "Castata zanjata!" If you want to ask a Russian to give you a call next time he hears you, why, just say, "Kagdá byi vyi ni uslýisali minjá pazálsta, vizavítje minjá" (and don't forget the accent marks).

Some You Have to Hear

Language tapes are necessary for those languages which English-speaking people find hard to pronounce. Japanese pronunciation is fairly easy and regular. You could probably make yourself understood in Japanese without the tape if the authors would explain the phonetic systems they use. Romanization is used for Japanese and Russian, but the conventional spelling of languages written in the roman alphabet is given. Just a list of the kana syllabary used to write Japanese would help readers pick out the pronunciation much more easily. The standard romanization of Japanese used in the *Guide* can mislead. For example "five years," *gonenkan*, is pronounced "go-nen-kan," not "gon-en-kan."

A one-hour tape of any language in the *Guide* costs $9.95 plus shipping. Text supplements cost $1.75 per language. You can order *The Radio Amateur's Conversation Guide*, by Jukka and Miika Heikinheimo, from *CQ Communications*, Main St., Greenville, NH 03048. Tel. (800) 457-7373. The price is $9.95 plus $3.75 postage.

Spanish and Russian

"Hola CQ," by "Doc" Schwartzbard AF2Y, gives you all the sentence patterns and vocabulary you need to carry out a basic QSO in Spanish. Many hams who took high school Spanish will find that the sentence patterns come back. Their new ham vocabulary also makes them want to learn more Spanish by radio.

The ARRL's "Hola CQ" consists of fine Spanish lessons for hams. A 90-minute cassette tape accompanying the text teaches the basics of Spanish pronunciation as well as the pronounciation of each phrase in the text. AF2Y reminds us of the many words Spanish shares with English and other romance languages, and how recognizing these words will speed our progress. You can get "Hola CQ" from the ARRL, 225 Main St., Newington CT 06111. It costs $7 plus postage.

Once you have mastered some phrases in your chosen language, you might try to find a night course at a local high school or junior college. You could also pick up a first-year college textbook on the language to get a systematic introduction to vocabulary and grammar. With your access to on-the-air tutoring, you may become an outstanding ham linguist.

Russian and Japanese in Particular

Other language lessons for hams are available. Len Traubman, with the help of some Russian hams, wrote "Russian Phrases for Amateur Radio," a 20-page booklet. The accompanying audio cassette tape is for English-speaking hams who want to communicate in Russian. The booklet contains English words and phrases for ham contacts, with Russian translation and transliteration for each phrase. You can get the booklet for $5 ($7 overseas) and the audio cassette for $6 ($8 overseas) from Len Traubman W6HJK, 1448 Cedarwood Drive, San Mateo CA 94403.

You can also download "Japanese for Hams," a 12-page guide I have written on making simple QSOs in Japanese, free from the *73* landline BBS (603) 525-4438; or from JAHAM in the files section of the N4QQ packet BBS. Call K3AF-7 in Washington, DC on 28.195 MHz 1200 baud, connect to K3AF-3, and then to N4QQ.

Goh Kawai 7L1FQE/N6UOK, a linguistics scholar at Stanford University, is working on a text of Japanese lessons for hams. You can contact him at CompuServe 76056,1726. If you get more serious about learning Japanese, you can order *Japanese for Beginners* and *Japanese for Today*, edited by Yasuo Yasuda, and published by Gakken, from Kinokuniya, 10 West 49th St., New York NY or from some other bookstore. Tapes accompany the text.

After you have worked on Japanese for awhile, you will find reading articles in *CQ Ham Radio*, the wonderful telephone-book-size (!!!) ham magazine from Japan, a great incentive to improve your Japanese. You can order *CQ Ham Radio* through Nihon IPS, Iidabashi 3-11-6, Chiyoda-ku, Tokyo 102 JAPAN for about $120 per year. You may be able to order single copies of it, or of its more technical cousin *Ham Journal*.

As the karatkavalnaviks (hams) say back in the U.S.S.R., "Zeláju vam udáci i mnóga di-eks": I wish you good luck and lots of DX. 73

David Cowhig has translated articles in Japanese for us and written articles on ham radio in Japan.

QRP

Low Power Operation

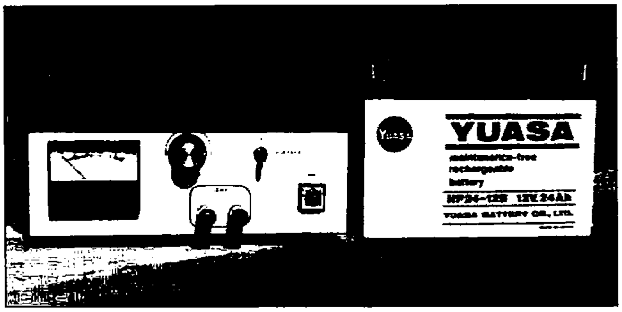

Photo A. The pulse charger—upgraded to handle larger batteries.

Mike Bryce WB8VGE

Massillon OH 44646

The Pulse Charger

The use of batteries in portable QRP operation captivates the attention of a lot of people. In the August 1989 column, I discussed a small pulse charger for Gell/Cell™ batteries. This project produced huge piles of mail. The original circuit has been changed slightly, to improve switching, and a PC board is now available to speed construction.

Perhaps a quick review of the circuit is in order. The Gell/Cell battery is charged using high current pulses, rather than a constant current. High current pulses won't heat up the battery, which reduces the chance of damage.

Operation is simple. A 555 timer operating as an astable oscillator provides adjustable pulses to an IC voltage regulator. The duty cycle of the oscillator may be varied by the front panel 50k pot. This control adjusts the current to the battery by varying the pulse width from the 555 oscillator. The output of the 555 is coupled to the base of the 2N2222 transistor via a 1N914 diode. This diode protects the 555 just in case the LM317 goes out to lunch and takes the 2N2222 with it for company.

When the output of the 555 timer goes high, the transistor is turned on. This shorts out the ADJ line of the LM317, shutting it off. Thus, no current will go to the battery. When the 555 timer is off, so is the transistor, allowing the LM317 to operate at the voltage selected by one of the 5k trimmers. In a nutshell, when the 555 is on, the LM317 is off.

The 5k trimmers set the state-of-charge for the battery. For cycle use, a Gell/Cell battery should have a full state-of-charge voltage of 14.4 volts. For standby use, select 14.0 as a full state-of-charge voltage. I also have a handful of 6 volt gelled batteries I use now and then. So, the second voltage I selected is 7.2 volts.

NiCds

A note about NiCds before we get too far into this project. When this charger first came out, many of you asked about charging up HT batteries. Well, you can—*if* you understand some of the limits of both the charger and the NiCds. First and foremost, HT batteries are all different. Batteries that came with the HT and those you have replaced from a third-party vendor may be different. In most cases they *are* different.

I know of one particular battery pack that does some magic when dropped into the manufacturer's quick charger. The battery pack is normally 12 volts, but a small relay inside the battery pack switches the batteries to a 6 volt configuration to allow high speed charging. To keep things from blowing up, a heat sensor glued to one of the cell's case will open up, stopping the charge current until the cell has cooled down. Some third-party battery re-fitters don't include this sensor. How many of us, in repairing an HT battery pack, have removed the sensor?

If you use the pulse charger to charge up the NiCds for your HT, limit the current to whatever value is listed on the battery's charge table. After you get the feel of things, you can increase the current.

Construction is very easy, thanks to the circuit board supplied by Far Circuits. Not knowing what everyone has in the junk box, I laid the PC board out to use several different styles of the LM317 and diode bridge. Use whatever version of LM317 you have, either in the TO-220 case or the TO-3 case style; BUT NOT BOTH AT THE SAME TIME. The same goes for the diode bridge. You can use either four individual diodes or a bridge rectifier pack from Radio Shack (RS 276-1146), but not both. I prefer the Radio Shack part myself; it's easier to install on the board.

The filter capacitor is also mounted on the PC board this time. A 2200 µF capacitor is used. This value is not especially essential; you can use as low a value as 1000 µF and as high a value as 10,000 µF. The filter smooths out the DC from the bridge so the 555 timer sees a nice smooth Vcc. The 78L12 provides a regulated +12 for the 555 timer. Don't forget to use the bypass capacitors on the 78L12.

Keeping it Cool

The LM317 can get kinda hot. In my prototype, it got too hot. (How hot did it get, Mike?) It got so hot the black heat sink turned silver! It was my fault. I was charging up 24 amp/hour batteries. This was way too much current for the one amp LM317 to pass. I was really surprised that it didn't fry the LM317! One way of generating too much heat is over-sizing the transformer. For 12 volt charging, use only an 18 volt trans-

Parts List for the Pulse Charger

Part	Description
U1	78L12 voltage regulator
U2	555 timer IC
U3	LM317K (or LM317T) adjustable regulator
Q1	2N2222 NPN transistor
D1–D4	1N4001 (or bridge rectifier RS# 276-1146)
D7	1N4001
D5,D6	1N914 diode
C1	2200 µF, 35 V electrolytic, axial
C2,C3	2.2 µF, 35V tantalum
C4,C7	4.7 µF, 35V tantalum
C5,C6	0.1 µF ceramic
R1,R3,R4	2.2k, ¼W resistor
R2	50k potentiometer
R5	220 ohm, ¼W resistor
R6,R7	5k potentiometer
T1	18V at 2A AC transformer

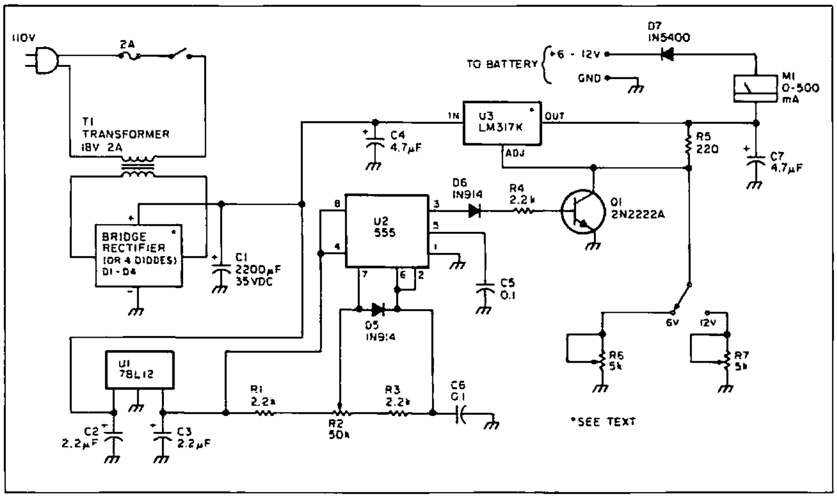

Figure 1. Schematic for the pulse charger.

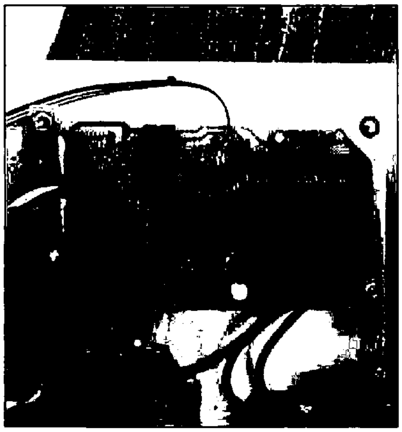

Photo B. Prototype PC board used in charger. Note the extra resistor soldered to the capacitor. Now the resistor is on the board. Just under the larger capacitor, the LM317 is bolted to the metal chassis.

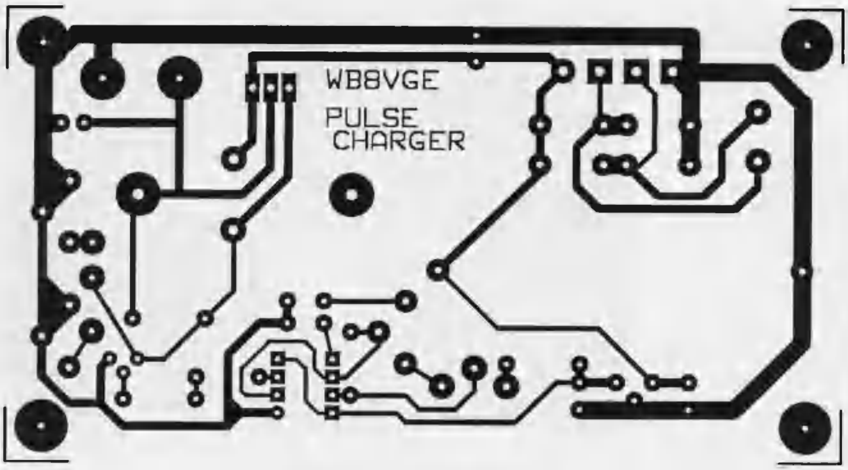

Figure 2. PC board foil pattern.

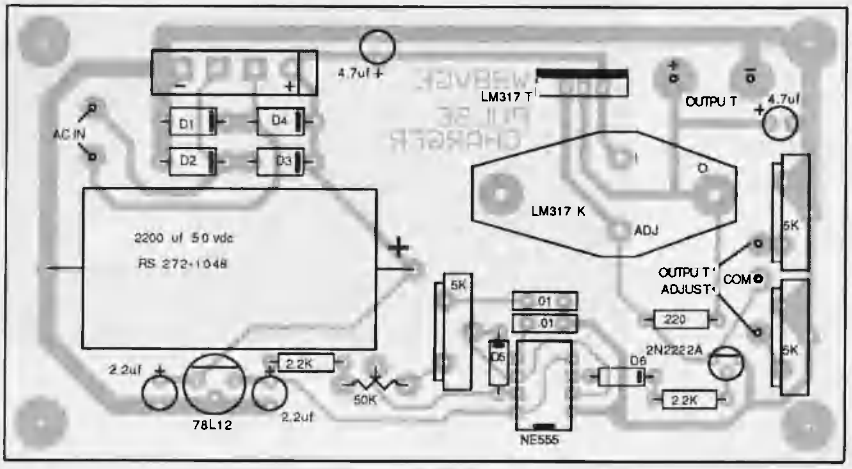

Figure 3. Parts placement.

former, no more. If you regularly charge HT batteries or 6 volt gells, a 12 volt transformer will do just fine.

If you want to charge larger batteries, use the LM350K. This device is good for 3 amps of current. In any case, to keep your charger from becoming your own personal Three Mile Island, you have to heat-sink the LM317. If you use the TO-220 case, you have an easy option. Just use the metal chassis as a heat sink. You have to insulate the case from the chassis, as it is hot. Radio Shack sells a mounting kit for the TO-220 for a buck.

If you go this route, use 1/4-inch spacers for the board, and solder the leads of the LM317 from the foil side of the board. Bend the LM317 back down so it will lay flat against the chassis. Spread some heat-sink compound on both the LM317 and the chassis to improve heat transfer. Don't forget to insolate the LM317 from the chassis. Pre-fit everything before you drill holes into the chassis.

Another option is to use the TO-3 case, LM317. The PC board is big enough to hold it and a heat sink. Because there are many different styles of heat sinks on the market, it's a good idea to make a dry run to be sure everything fits before soldering.

Easy Set-Up

Remove the 555 timer and lay it aside. Apply power to the circuit. Check for +12 volts at pins 8 and 4 of the 555. Select one of the trimmers. Set it for 14.4 volts. Set the other for 7.2 volts. Again, you can set these for whatever value you want or need. If you use the blocking diode, set the voltage on the battery side of the diode. This blocking diode is not on the PC board. You really don't need it, but if you're like me and forget to disconnect the battery and to power down the charger, the battery will discharge into the charger. The diode prevents this from happening.

In the prototype, I used a 0–500 mA meter. I found this to be too small for the batteries I was charging. Use a 0–1 amp meter if you plan on charging 4.5 amp/hour or larger batteries.

Power down the charge and let the caps discharge. Replace the 555 timer. With a battery connected to the output, power up the charger. With the duty cycle control, set the current for proper charging. Remember, the meter will average out the reading from the pulses going to the battery. That's about all there is to do. When the battery becomes fully charged, the current will drop to a very low reading. How much current is flowing when the battery is fully charged depends on the type of battery, battery size, and of course, the battery temperature. Don't use the charger to operate any of your gear!!

Kit Available

To make it easier to get this project going, I can supply a complete kit of parts for the charger. The kit will contain all of the PC board components. There won't be too many of these kitted up, so don't wait too long. Cost of the PC board and parts is $29.95, plus $2.50 for postage.

That should take care of all your portable batteries. No reason to not pick up the HW-9 and head for the woods. Ah yes, QRP; better living with less. 73

HAMS WITH CLASS

Carole Perry WB2MGP
Media Mentors, Inc
P.O. Box 131646
Staten Island NY 10313-0006

The Dayton Youth Forum

For several months prior to the 1991 Dayton Hamvention, I was concerned about finding dynamic youngsters who were also active hams to speak at the Youth Forum I was going to be moderating there. I was also anxious about how many hams would be bringing their own youngsters with them to the Forum, as we had been publicizing and advertising in all the ham magazines.

Happily, all anxieties were for naught. The Youth Forum got off to a flying start when astronaut Tony England WØORE stopped by to wish us well, and offered to speak to the standing-room-only audience.

Dr. England was appointed a NASA scientist-astronaut in 1967, and acted as mission scientist for the *Apollo* 13 and 16 flights. He also flew as a mission specialist on the space shuttle *Challenger's* Spacelab 2 mission in 1985. Currently, he is professor of electrical engineering and computer science at the University of Michigan in Ann Arbor. There he both teaches and conducts research on microwave emission, propagation, and scattering.

Tony England enchanted everyone with his stories of how he and his high school ham friends used their knowledge of Morse code to better "communicate" during tests. The audience of more than 60 youngsters, plus all the adults who attended, were privileged to hear Tony speak of his interest in amateur radio as a vehicle to interest young people in science and engineering. With few and progressively fewer bona fide role models for young people in today's society, Tony England made a superb opening speaker for the 1991 Youth Forum at Dayton.

Dynamic Speakers

After such an auspicious introduction, the young speakers had no problem picking up the ball and impressing the audience with their eloquence, composure, and dedication to amateur radio.

The first young speaker on the agenda was Todd Tittle KF7LX from Sedro-Woolley, Washington. This personable 17-year-old is an Advanced Class license holder and president of his high school amateur radio club. Todd was secretary and treasurer of the Western Country Cousins Net, for which he also served as net control. His apparent ease at the microphone at a national convention spoke well for his experiences at the radio over the last several years. Todd attributed his original interest in ham radio to his grandfather. He encouraged the young people who were present to pursue different areas of the hobby and have fun with it.

Willis Almekinder KB2LEP is a 15-year-old ninth grader from Lyons, New York. Despite his young age, Willis is a member of RACES, and has used his New York Disaster Preparedness Commission identification card to get past road blocks and into the center of emergencies to offer assistance. He has already made a career choice that will take advantage of his outgoing demeanor. Willis wants to combine an extensive electronics knowledge with an interest in law, and to argue cases that involve high technology. Willis encouraged the youngsters in the audience to consider getting involved with emergency preparedness in their local areas.

Sammy Garrett AAØCR was next at the podium. This articulate 13-year-old from Florissant, Missouri, has an Extra Class license. Sammy and I spent some time together talking at the convention leaving no doubt in my mind about why he was selected the 1991 Westlink Young Ham of the Year. He amazed the audience with his aplomb, and encouraged the adults to share their enthusiasm with the youngsters they wanted to recruit into ham radio. Sammy suggested that we all look for the "little child" in ourselves when speaking to young people. He made an enormously favorable impression on everyone.

Photo A. Astroham Tony England WØORE got things off to a flying start with Carole Perry WB2MGP at the Dayton Youth Forum.

Photo B. Sammy Garrett AAØCR, the Westlink Young Ham of the Year, encouraging adults to share their enthusiasm with youngsters.

Photo C. Lenny Mack KB8KTC participated in Moonbase America.

Brian Cresenzi KB2GTD, a 14-year-old from Ryebrook, New York, shared his experiences as SAREX (Shuttle Amateur Radio Experiment) net control at Blindbrook High School, New York, for the STS-35 mission last December. Brian made the initial contact that gave students at his school a chance to ask questions of Ron Parise WA4SIR, payload specialist on board the *Columbia*. Brian and his dad, KB2GTE, are members of the Westchester Emergency Communications Association. Someone in the audience commented to me on how wonderful it was for young people to be playing such an active role in some of the most extraordinary events in the world today. Amateur radio has provided an unparalled opportunity for children to become motivated about tomorrow's possibilities in technology.

Lenny Mack KB8KTC is a tenth grader who had the incredible experience of participating in the Moonbase America project during the third week of April 1991. Moonbase America is a national educational project created in conjunction with NASA. Project headquarters is in the Copely-Fairlawn City Schools in Copely, Ohio. Lenny explained that the project is a simulated moon-station constructed out of geodesic domes. Moonbase, designed to provide a lunar environment where students could study science, was located beside the tennis courts of Copely High School. As a command controller, Lenny described how ham radio played a major role in the communications setup of this course for teaching students how to live on the moon, and to appreciate the value of teamwork and individualization. *[See the April "QRX" for more details about Moonbase America.–Eds.]*

All Hopes Fulfilled

I hope never to conduct a youth forum that doesn't include at least one distaff member. Through the generosity of several hams, **Mary Alestra KB2IGG**, a 13-year-old from my class, was able to attend Dayton and speak at the forum. This Extra Class license holder was the 1990 Westlink Young Ham of the Year. She has gone on to be an inspiration for many other young people, especially girls.

It was my profound hope when we began this that the Youth Forum would showcase young people who were accomplished, involved, and having fun in amateur radio. It was a personal honor to be able to bring together such an outstanding representation from across the country. It was clear to anyone in attendance that day that at least some of the not-yet-ham children attending the forum will be considering the possibility of joining our ranks.

Thanks must go to the members of DARA who are always so supportive of educational efforts, and to everyone in the ham community who encourages and lends support to youth-oriented activities, thereby ensuring continued recruitment of bright, energetic, and dedicated young people.

AMSAT at Dayton 1991

If you haven't made the trip to the Dayton Hamvention at least once, plan now to attend next year. Over 30,000 hams were on hand for a ham radio convention of gigantic proportions. I thought the Houston gathering was large and the one from Dallas huge, but both paled before the massive assembly of commercial exhibitors, presentations, swapfest enthusiasts and ham participants that took over southwestern Ohio for a long weekend in April.

The event organizers outdid themselves with quick registration, shuttle buses to outlying parking areas and talk-in information on 2 meters, 220 MHz and 70 cm. The convention guide was a full-sized magazine, not just the simple forum list so common at other ham conferences.

AMSAT was well represented with speakers in the meeting rooms and informed volunteers at the booth in the commercial exhibit area. Most of the AMSAT board members and officers attended and were available at the Hamvention to answer questions about the amateur radio satellite program.

AMSAT President and General Manager Doug Loughmiller KO5I spoke at a forum about the successful launches of several new hamsats in 1990. Lou McFadin W5DID and AMSAT Director Tom Clark W3IWI described the Shuttle Amateur Radio Experiment (SAREX) equipment used on board STS-35 and STS-37. Lou showed a tape of amateur television video as received by Ken Cameron KB5AWP on the recent STS-37 mission. Dr. Tony England WØORE, who took ham radio to space on a shuttle mission several years ago, spoke on the educational benefits of the SAREX operations.

AMSAT Director and Vice President of Manned Spacecraft Operations Bill Tynan W3XO touched on future shuttle and space-station activities, while AMSAT Director Dr. Bob McGwier N4HY discussed the Microsat programs under consideration or construction in several international locations including Mexico, Australia and Italy.

Back at the AMSAT booth, in addition to the excellent advice and help offered by the volunteers, AMSAT had new publications for sale. *Decoding Telemetry from the Amateur Satellites* by G. Gould Smith WA4SXM provides an in-depth look at all the current hamsat telemetry schemes from the simplest CW on AMSAT-OSCAR-21, to the complexities of the University of Surrey satellite systems.

The Satellite Experimenter's Handbook has been completely revised by author Marty Davidoff K2UBC. The result is an updated and expanded reference book for both beginners and longtime hamsat enthusiasts. Although the price is up to $20, this 350-page volume covers all the bases when it comes to satellite chasing.

A Beginner's Guide to OSCAR-13 by Keith Berglund WB5ZDP is into another print run. AMSAT ordered a large batch of these popular booklets to be ready in time for Dayton and for potential sales through 1991. For a bargain $7, you learn how to get a fully-functional station on the air for the high-orbit satellites.

A new Webersat manual was offered in loose-leaf form from Weber State University. AMSAT carries this publication for WSU at $15 per copy. For those looking for more data on the inner workings of Weber-OSCAR-18, this edition provides some useful insight.

No new versions of "Instant Track" and "Quiktrak" were introduced this year. The current software packages continue to outperform many amateur and commercial offerings. In addition to the IBM-PC software, AMSAT carries tracking programs for the Commodore, Macintosh, Apple II, Amiga, Tandy CoCo and HP calculator. Software for the older TRS-80 computers and Sinclair machines is no longer supported.

You can get details on prices of the AMSAT software offerings, and publications can be obtained by calling AMSAT at (301) 589-6062 during normal East Coast business hours. Inquiries can also be sent to AMSAT, P.O. Box 27, Washington DC 20044.

RS-14/A-O-21/ Radio-M1/RUDAK-2

This new amateur satellite has brought back the excitement of easy-to-copy strong signals via Mode B (70 cm up with 2 meters down) from low earth orbit. As one longtime hamsat enthusiast said while making a contact via the transponder, "It's like OSCAR-7 all over again, only 6 dB better!"

From its 620-mile-high orbit, RS-14, also known as AMSAT-OSCAR-21 or Radio-M1 or RUDAK-2, is providing excellent communications to stations not yet fully configured for operation on AMSAT-OSCAR-13's high elliptical orbit. This joint Soviet/German satellite is a part of a Soviet geological research satellite. It offers several modes of operation, but the most promising is the transponder system. Frequency charts were published in the May 1991 "Hamsats" column.

Simple systems with omni antennas can access the analog transponder with SSB and CW with ease. Mobile and portable operation with the clarity of Mode B is now a realistic possibility. While the specifications of the uplink/downlink system appear similar to OSCAR-7 (launched in 1974 and operational through 1980), the signals sound much stronger. This could be a result of many years of high-orbit Mode B transponders on A-O-10 and A-O-13 and the extra effort needed to equip ground stations to receive the weaker signals from orbits ten times higher than A-O-21's.

Advances in receiver performance over the last 17 years and small high-power transmit radios give today's A-O-21 enthusiasts an edge over the homebrew and exotic equipment users of two decades previous.

During late May and early June, experiments were underway to test the systems of A-O-21. Some oscillation problems were noted in the preamp of linear transponder number 1. Linear transponder number 2 was operating normally, but due to the investigations of the complete system, it was not always active. Some even heard it switch off in the middle of a pass without ground-station commands.

The best way to check on the satellite and its functionality is to monitor the CW telemetry. For linear transponder two, the data can be heard on

Photo A. AMSAT's booth at the Dayton Hamvention (l. to r.): AMSAT Coordinator Mike Crisler N4IFD, AMSAT President Doug Loughmiller KO5I, and AMSAT Corporate Secretary Martha Saragovitz.

Photo B. AMSAT Executive Vice President John Champa K8OCL answers another question about satellites at the Dayton Hamvention.

145.948 MHz. Decoding the number groups is simple. A typical frame of telemetry consists of eight four-digit numbers.

An actual sample of data copied in late May looked like: PPPPRS14/7007/7116/7224/7316/7409/7500/7600/77. To decode the data, refer to Table 1.

The first four-digit number was "7007." The first digit defines the channel status. A prefix of "6" identifies a general status, while a "2" identifies a command status. The "7" is likely a general status. The second digit, a "0," is the channel number. Channel "0" defines the transponder output. The last two digits give the power level output in watts when multiplied by 0.05. For "07," the result is so close to zero watts that it is assumed the transponder is off. A number in the neighborhood of "80" would give a nominal reading of 4 watts.

The second four-digit number gives the status again as "7," with the channel number as "1." The last two digits, "16," show the transponder power amplifier temperature to be 16 degrees Celsius. If the transponder were on, a higher number with resultant temperature would be expected.

For the remaining channels, the effects are easy to compute. A calculator isn't needed. The numbers directly reflect voltages and temperatures as detected on the spacecraft. Information for decoding the data on channel "7" is not currently known.

The most important number to those wishing to make contacts via the satellite is the value of channel "1." Anything above "40" should reflect active transponder operation. Although DX activity is limited due to the height of the orbit, excellent communications to a few thousand miles range will provide some very satisfying contacts from A-O-21/RS-14. ■

Channel	Parameter	Formula	Unit
0	Transponder Power Output	0.05•N	Watts

AC ELECTROMAGNETIC FIELD RADIATION MEASUREMENT

ELF-50D FIELD MONITOR

GENERAL:
The ELF-50D Field Monitor is a low-cost, portable, hand-held instrument designed and calibrated to measure low level 50 Hz or 60Hz electromagnetic field radiation generated by power lines, video display terminals (VDT's), TV sets, home appliances, industrial machinery and other similar devices.
CALIBRATION TRACEABLE TO NIST (PREVIOUSLY NBS).

More DXing Techniques

One of my friends told me recently that he had used what can be considered a bad technique to work a new country. He wasn't necessarily proud of the fact, but after several unsuccessful days of using conventional techniques, he finally broke down and worked the elusive station by "calling out of turn," or "breaking-in." He did this only after he heard another station successfully work the DX station using this technique. This should remind us that there is more than one way to work DX in pile-ups.

Calling on or near the same frequency at the same time as a station working the DX station is considered by many to be rude or unethical. But it is done, and it is too often successful. A more appropriate technique is "tailending."

Tailending means transmitting your callsign on or near the same frequency as the station working the DX station immediately after that station finishes. Tailending is especially successful on CW, and it can be effective in SSB pile-ups as well. But it is not an easy technique to master.

Tailending used against an inexperienced DX operator often causes more problems than successes. A poorly executed tailend does nothing more than QRM the calling station, and more than likely will require the DX station to ask for a repeat, thus slowing his QSO rate. An excellent discussion of tailending is provided by Wayne Mills N7NG in the newly published *Where Do We Go Next?* by Martti Laine and others (KTE Publications, 2301 Canehill Avenue, Long Beach CA 90815). Wayne, an experienced DXpedition operator, shares his experience in Appendix I.

CY9 St. Paul Island

Jan VE2OL reports that a group of amateurs from the West Island Amateur Radio Club (VE2CWI) in Montreal will activate St. Paul Island August 1–7 with the callsign CY9CWI. The list of operators includes VE2SEI, VE2WHO, VE2JBF, VE2DAV, VE2PTT, VE2GZV and VE2OL. Three stations will be active during this operation. The following frequencies have been mentioned: CW—1820, 3520, 3680, 7040, 14050, 21110 and 28050 kHz; SSB—1870, 3795, 7060, 14195, 21295 and 28495 kHz. CY9CWI will also be active on the WARC bands. QSL via VE2CWI.

St. Paul Island sits in the Gulf of St. Lawrence just off the northeast coast of Cape Breton Island, Nova Scotia. Outside of Nova Scotia, few know about it — encyclopedias don't even mention it, and the usual know-it-all geographical dictionaries merely mention its location. But to many residents of Nova Scotia, and to those people who have been there, St. Paul Island is remembered as the graveyard of the Gulf of St. Lawrence.

As many as a thousand deaths have been attributed to the rocky embraces of the island. One of the first recorded shipwrecks was of the English transport *Royal Sovereign*, which was carrying troops home from the war of 1812. Of the 311 men on board, only a dozen or so survived. In 1825 the Canadian barque *Jessie* ran aground on the island during a snowstorm. The crew was able to get ashore, but they died of starvation.

The island, which actually consists of two islands and several rocks, resembles an exclamation mark (!). It's three miles long and averages 1-1/4 miles in width. It is currently inhabited by two lightkeepers who stay on the island for 28 days. Around 1900 there were as many as 40 people living on the main island. There was a post office, a cannery, a school and a telegraph office. The lighthouses were first built in 1838.

The main island, heavily wooded with stunted spruce, is about two miles long. The island on which the lightkeepers live (and DXers operate!)—the dot of the quotation mark—is about two acres in size and about 40 feet above high water. Lighthouse keeper Mel Tanner describes it as "this desert Island of ours." Tanner also mentioned that the island is "...surrounded by a rough, rugged shoreline so exposed to disturbances that we are constantly overcast in spray during winds of any velocity."

Yuri Blanarovich VE3BMV, writing about the XJ3ZZ/1 DXpedition in the November 1977 issue of *CQ*, had the following to say about St. Paul. "St. Paul lies 18 miles northeast of the northern end of Cape Breton Island. It is small, rocky, and practically desolate. The northern point is a detached pinnacle, which appears from seaward to be joined to the main island, but it is separated by a narrow channel about 100 feet wide from the peninsula. The main part of the island rises in two parallel ranges of hills, the southeast being the higher with a summit of 485 feet....

"There are two lighthouses on St. Paul, one on the detached rock forming its northern extreme, and another on its southern point.... The only access to the small island is through the channel separating both islands, and only by small boat. Wooden platforms and walkways abound over the island. It is very difficult to walk on the island during bad weather, as the rocks are slippery and dangerous, but walkways connect all buildings on the island." Yuri also mentioned that "the expedition was not what you would call a pleasure trip, but hard work...."

St. Paul Island qualified as a separate DXCC country based on "separate administration." St. Paul, like Sable Island, was administered by the Federal Department of Transportation. This was established by an act of Canadian Parliament as part of the Canadian Shipping Act.

There have been several DXpeditions to St. Paul since it was added to the DXCC list of countries. The first signed the special callsign VY0A. Other operations included XJ3ZZ/1, VE1CR/1, CY0SPI, CY9SPI, CY9DXX, W5KNE/VE1 and CY9CF. The callsign CY0SPI was issued to the island to be used by ALL operations, but without any obvious reason the licensing authorities changed it to CY9SPI. The island callsign for Sable Island was changed from CY9SAB to CY0SAB at the same time. (Adapted from an article by W5KNE published in the August 1, 1988 issue of *QRZ DX*.) See the photo.

British Virgin Islands (VP2V)

Arch K8CFU, who will be visiting the islands August 16 through 25 with his wife, will be active as VP2V/K8CFU. Look for him on 20 meter SSB. QSL to Arch's *Callbook* address.

Greenland (OX91)

Laurent F6GOX (ex-TK5BL and FJ5BL) is a member of a scientific expedition scheduled to be in Greenland during July and August. Laurent should be active on the HF bands as OX91REF. The callsign of his 6 meter beacon on 50.100 MHz is OX91BCN. QSL via F6AJA.

DXing How-to Books

There have been several excellent DXing how-to books published in recent years, but the two that I believe are the best for new DXers are *The Complete DX'er*, by Bob Locher, W9KNI and *The DXCC Companion* by Jim Kearman KR1S.

Jim's book brings the beginner into the hobby of DXing at an easy pace and Bob's book, written in an interesting narrative style, sharpens the techniques.

Both books are available from major ham radio book outlets. You might want to check "Uncle Wayne's Bookshelf" in this issue of *73*, too.

New Islands-On-The-Air Directory

The new *IOTA Directory*, all 50 pages of it, is now available. It includes a fully updated list of islands to work for the IOTA Awards program and fully revised IOTA rules. Price: Europe—$10 or 15 IRCs; other countries—$12 or 18 IRCs. Send requests to IOTA Director Roger Balister, G3KMA, La Ouinta, Mimbridge, Chobham, Woking GU24 8AR, England.

BARTER 'N' BUY

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The *73 Flea Market*, Barter 'n' Buy, costs you peanuts (almost)—comes to 35¢ a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to the *Barter 'n' Buy*, Sue Colbert, Forest Road, Hancock NH 03449 *and get set for the phone calls.*

Lasers and Photomultiplier Tubes

It has been a year since the FET switcher AC power inverter appeared in this column—August 1990, in fact. The basic switch driver has been used in quite a few different applications. The photomultiplier tube (PMT) covered this month uses a modified version of this power supply to deliver the high voltage required for proper operation. The PMT is a sensitive detector used in the receiver portion of the system. Now for a little about the power supply and PMT requirements.

PMTs and Gain

The laser receiver described last month used a low voltage pin diode. Further improvements can be made by using a PMT with higher sensitivities. The pin diode circuit is modified by removing the first op amp to prevent too much gain from the PMT. In the end I used a single op amp tied directly to the LM386 audio amplifier. Steve Noll WA6EJO used an LM387 in his system, and experimentation proved him correct. The modifications are due to the fact that PMTs are much more sensitive when compared to photo diodes. In fact, PMTs have gains (current amplification) that run in the millions!

Photomultiplier tubes are electron tubes that receive light (a stream of photons) and convert it to electric current. A photo cathode, the first element of the tube, intercepts the light, then emits electrons (or, if you prefer, repels electrons because it's intercepting positive photons) towards the first dynode.

This first dynode is more positive than the cathode, and attracts the electrons. However, due to electron bounce, when electrons hit the dynode, they collide with other electrons on the dynode and join the original electrons at some exit angle. They are attracted by the next dynode (more positive) before they can return to the first dynode. See Figure 1. You might also use the old pool-table analogy to visualize all this activity. This process continues through nine successive dynode stages, providing very high current gains for a very small input signal.

Electron bounce happens in every electron tube, but a grid type structure near the plate, called the suppressor, is tied to the cathode potential. It repels electrons, sending them back to the plate and reducing secondary emissions. In the PMT, the opposite is required in order to obtain current gain.

PMTs can be so sensitive that when they are used for very low light applications, such as astronomy, they are contained in magnetic shields, and cooled to very low temperatures. The magnetic shielding limits external forces affecting the electrons as they are reflected internal to the tube's elements (dynodes), and maximizes performance.

As you can see in Figure 2, the internal construction of the dynode is different in the various types of PMTs. Some types are: the Side-On, the Head-On (compact, with fast response; like the 931), the Box-and-Grid (generally provides best uniformity and sensitivity), and the Venetian Blind (high output, slow response time). All of these PMTs work very well, as time response is not a critical factor for our applications.

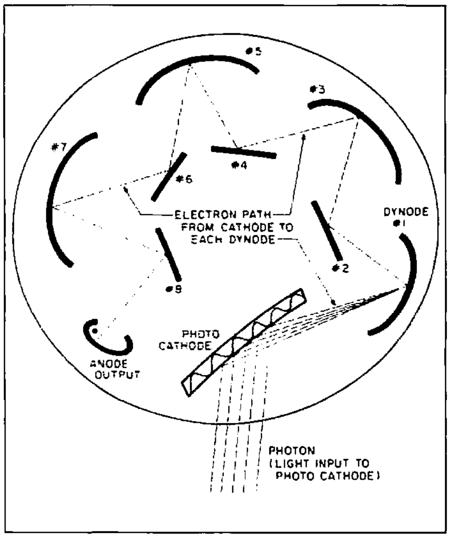

Figure 1. The 931 photomultiplier (PMT), showing current path from photo cathode (light input) to each dynode involved in current amplification. Current gain is very high.

The 931 and similar types of PMTs require a power supply voltage near 1000 volts, and 2 to 3 mA of current for the tube and resistor network. The power supply connections for a 931 PMT are shown in Figure 3. This resistance network is usually contained in a well-insulated tube socket base.

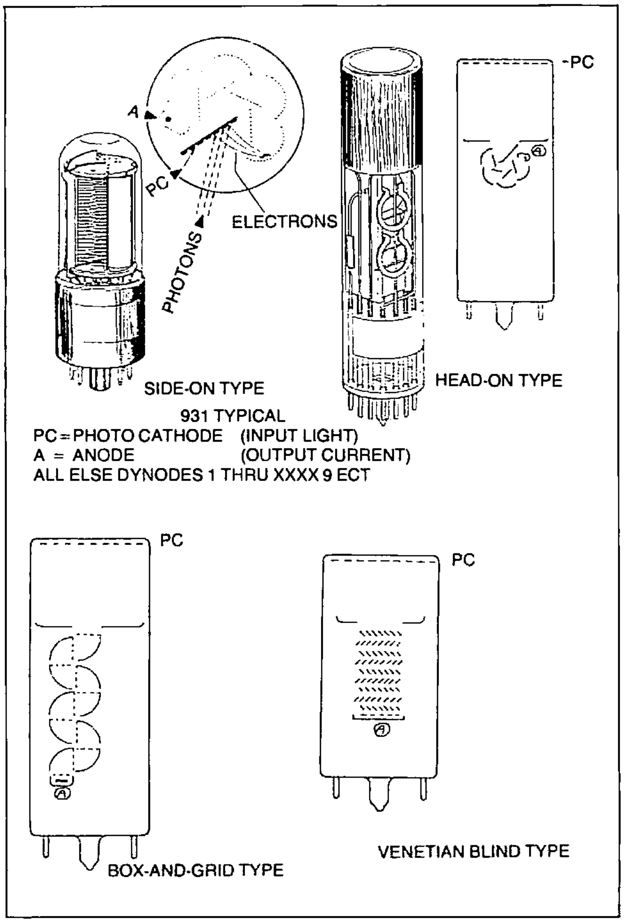

Figure 2. Various types of photomultipliers.

The change to the circuit is minimal. With a PMT, all you need is a high voltage capacitor coupling the PMT's output to the detector's audio preamplifier circuit. A high voltage capacitor is necessary since PMTs operate at a potential around 1 kV, and you don't want high voltage leading into the low voltage audio circuit.

The Power Supply

The PMT power supply uses the basic switch driver coupled with a hand-wound toroidal step-up transformer to produce a home constructed 1 kV power supply at a few mA. The power supply application was covered in detail in the August 1990 column. *[Ed. note: See the May 1991* Updates *section for the schematic.]* In that application, a 24 volt center-tapped transformer was used, driving it backwards, which made the primary the 110 volt AC output. Depending on the current rating of the 24 volt winding, you could obtain 100 or so watts of power at 110 volts AC from this simple system. In our application, the 24 volt transformer is replaced with a home-wound toroid step-up transformer.

The construction of a power supply meeting the PMT's voltage requirements fit well with the FET switcher design. What was desired was a system to operate from 12 volts for portable operation. Construction on a step-up transformer was started by winding a ferrite bobbin (cup core transformer). The cup core type was selected due to the ease of winding a high number of turns required for the secondary. The secondary was wound by hand, and a very small transformer resulted. By using a ferrite cup core transformer, the entire unit can be constructed in a very small container.

The ferrite bobbin/core can be ordered new or obtained in surplus. The transformer construction uses a single ferrite cup core that is about an inch and a half in diameter and an inch high. The cup core transformer is constructed of two identical ferrite halves that sit on top of each other and contain an internal plastic bobbin. This bobbin is removed to facilitate rapid winding. Compared to a toroid, the bobbin can be more easily wound.

The bobbin (transformer) is very similar to a sewing machine bobbin. I was able to wind a primary of 54 turns center-tapped #24 gauge wire with a layer of insulating Mylar and transformer tape (to isolate the primary from secondary) in about three minutes. The secondary required about 1800 turns of #36 gauge wire to obtain the 1 kV needed for the PMT. A small gauge

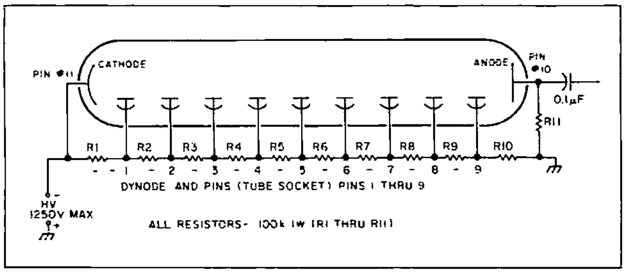

Figure 3. Schematic diagram of a 931 PMT, showing resistor network and high voltage.

wire is used for the secondary, since the PMT's current there is only 1 to 2 mA. The wire gauge is not critical.

In the initial test transformer, I scramble-wound the secondary in one large coil. I have to admit I lost count several times on the exact number of turns, but it was close to 1800. Normally I would have laid a layer of tape every 200 turns or so to give voltage flash-over protection on the secondary, but I didn't do this to the trial transformer.

The enamel wire should be good to 1 kV, but why push it as I did with the prototype? When finished I had plenty of room for the six or so layers of Mylar insulating tape, which would hold voltage to lower limits in each separated winding bundle. Other insulating material can be used.

it, as it can draw quite an arc that I don't wish to be near. Just use good insulation procedures and good construction techniques, and keep you hands out of it when it is on. Can't say it enough: SAFETY FIRST.

Mailbox

Joe Foss USN on the *SS Cleveland* writes that he found an old copy of *73* in Subic Bay R.P. He enjoyed the article covering the 30 MHz IF amplifier used in the receiver for 10 GHz microwave wideband FM. He wanted to build one, but knew that Radio Shack doesn't stock the main ingredient—the TDA-7000 chip. Well, Joe, the chip comes with the kit along with a few other parts that I can muster up to help defray costs. It's amazing how many of these

Once the transformer was completed, I found that due to an error in winding (turns ratio) I had too much output voltage for a current draw at 2 mA. I could have opened up the transformer and removed turns, but I decided it would be better to put a voltage regulator in the switching input circuit, and regulate the DC voltage. This way I could set the output voltage to compensate during test evaluations for different type of tubes. A minor variation, but part of the prototyping game.

All that was required was an LM317 adjustable voltage regulator. I set the voltage to the 9 to 10 volt range for input to the switcher and obtained 1 kV output with ease. A small pot controlled the DC regulated voltage. The LM317 required a heat sink, as it was passing a half amp of current at 12 volts for this circuit, but that's a small price to pay for such easy voltage control. I ran the prototype for three hours, and it did not falter. I did detect some transformer heating, but this was slight, as with the switching FETs. I am always suspicious of something that works the first time.

NOTE: Use caution with this power supply, as it can deliver a lethal jolt! Always keep safety in mind when working with high voltage. Do not think that just because it provides only a small current it is not serious. THINK AGAIN! If you need proof, this baby will provide

simple kits have surfaced on the microwave bands since the first article went out. I still use mine, and it did not have a PC board, being the prototype. Cost of the kit is still $10 postpaid.

Steve Caesar KF8LW is planning several microwave beacons using simple keyed CW oscillators for the bands 450 MHz and up (the 70cm, 35cm, and 23cm ham bands). I supplied a beacon CW IDer for the project.

Junji Tamura JH1MNOY obtained a phase-locked brick from me and reports it arrived safely in Japan. He was very happy to find some SMA connectors and voltage regulators in the package. These are difficult to get in Japan, he says. When Junji completes the negative 20 volt power supply, the brick oscillator will be tested in the lab at the Japan Amateur Radio League. I set the brick up for 10.0040 GHz to use with a 430 MHz SSB radio for operation on 10.475 GHz, their portion of the band.

I am gathering components for a weather satellite receiver operating on 1691 MHz, and I'll report on that when time permits. As always I will be glad to answer questions concerning microwave or related topics. Please include postage (SASE) for a prompt reply. Those without return postage will go unanswered, but may be answered in the column. Best 73s, Chuck WB6IGP. 73

ZD ENGINEERING PRESENTS
★★★★ THE CATV ★★★★
HARDLINE MATCHING TRANSFORMER

The ZD Engineering quarter-wave matching transformer is designed to provide an accurate and broadbanded impedance match between very low loss 75 Ohm CATV hardline and a 50 Ohm load. In addition it provides a reliable and inexpensive method of attaching type N or SO-239 connectors.

Matching transformers are built for the following frequencies.
144 MHz, 222 MHz, 440 MHz, 903 MHz, and 1296 MHz. Units below 200 MHz are built with type N or SO-239 connectors while all others are built with type N only.

Units are built to fit 1/2, 3/4 and 7/8 inch hardline.

Custom built transformers are available for any frequency between 100 MHz and 1.3 GHz as are units built to fit other sizes of hardline. When ordering, please include a 4 inch section of your hardline and specify the design frequency and connector type you need.

Price for 144 MHz units is $29.95 per pair plus $5.00 shipping UPS. 222 MHz, 440 MHz, 903 MHz, and 1296 MHz units are $27.95 per pair plus $5.00 shipping UPS. Ohio Res. add 5.5% sales tax. Custom built prices on request.

Units may be obtained from:

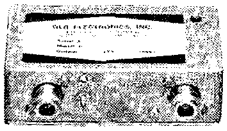
HIGH PERFORMANCE PRESELECTOR-PREAMP

The solution to most interference, intermod, and desense problems in repeater systems.

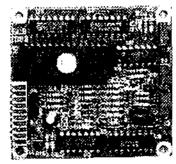


- •40 to 1000 Mhz tuned to your frequency
- •5 large helical resonators
- •Very high rejection
- •Low noise—high overload resistance
- •8 db gain—ultimate rejection >80 db
- •GaAs fet option (above 200 Mhz)
- •Cast aluminum enclosure
- •N, BNC, and SO239 connector options

Typical rejection:
±600Khz @ 145 Mhz: 28db
±1.6 Mhz @ 220 Mhz: 40db (44db GaAs) ±20 Mhz @ 800 Mhz: 65db
± 5 Mhz @ 450 Mhz: 50db (60db GaAs) ±20 Mhz @ 950 Mhz: 70db

AUTOMATIC IDENTIFIERS

- •Up to 8 EPROM programmed messages
- •Adjustable audio, speed & interval timer
- •"ID over voice inhibit"
- •Low power option
- •Modular design
- •Message selection via binary input—TTL levels
- •Size: 2.7 x 2.6 x 0.7"



NEW Model ID-2B

The ID-2B provides required station identification without troublesome diode programming. The "ID over voice inhibit" circuitry allows for courteous operation by not allowing an ID until the next squelch closing.

ID-2B Wired/Tested $99.95 **ID-2B-LP Low Power $109.95**

Micro ATV Transmitter

See the above article in the July '91 issue, page 9. Although the Micro ATV Transmitter will work as shown in the article, there are a couple of changes that will improve its performance. There is one error in the original schematic. As shown in the original article, the video clamping circuit will not function. This could cause sync loss (an unstable picture) during wide variations of scene illumination. To correct this, note the new location of the 1k resistor R9 (see Figure 1). Remove the chip resistor R9 from the bottom side of the circuit board and add a standard 1k, ⅛W resistor to the top side. This new resistor R9 should go from the junction of diode D1 and potentiometer R8 to ground (see the new parts placement diagram—Figure 2).

Note that the polarity of capacitor C7 was reversed in the original parts placement diagram. The correct configuration is shown here in Figure 2. Also when using the corrected circuit, you should increase the value of capacitor C7 to 100 µF with a 10 volt rating. Mouser part# 140-MLR10V100 is recommended for C7. One final note: when installing the MRF-911 transistor, make sure that the collector lead points towards the RF out connection.

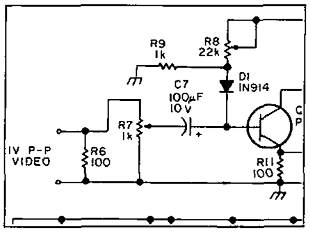

Figure 1. Corrected schematic for the Micro ATV Transmitter. Note new placement of R9.

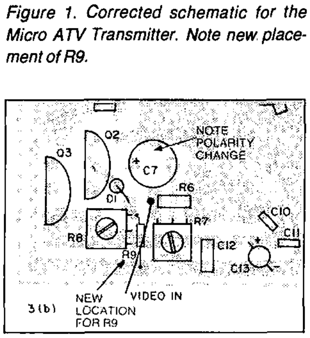

Figure 2. Correct parts placement for the Micro ATV Transmitter. Remove chip resistor R9 from the bottom of the board, then solder a 1k, ⅛W resistor to the top of the PC board as shown. Note also the correct polarity of capacitor C7.

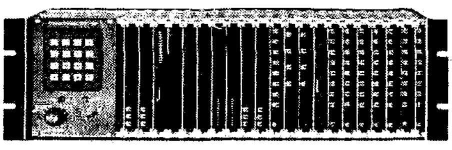
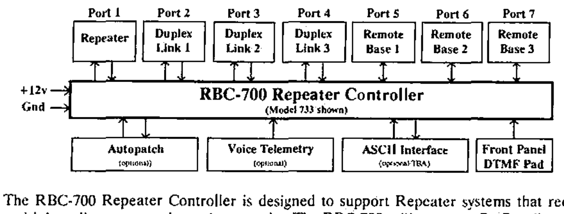
MULTIPLE REPEATER - LINK - REMOTE BASE CONTROLLER

Finally a controller that has solved control and audio interconnect problems between multiple radios. Your radio system can grow to multiple sites and stretch for hundreds of miles - and yet any radio can be fully controlled from any designated input.





The RBC-700 Repeater Controller is designed to support Repeater systems that require multiple radios connected together at a site. The RBC-700 utilizes a true 7 x 7 audio matrix switch which allows several conversations between ports at the same time. In the illustration above the 733 model is supporting a Repeater, 3 Duplexed Links to different sites, and 3 Remote Bases. Using simple commands, a user could tie the Repeater and a Remote Base to one Link, while the other Links are communicating through your site, holding separate conversations. Or, connect all of the ports together - like a big party line !!

Several models are available and are software configurable to support up to 3 Repeaters, 5 Duplexed Links, and 4 Remote Bases. A group or club can start with the basics and expand their controller anytime by simply adding boards and software. Free software upgrades for one year after delivery. Finally, a real controller for the Linked system operator !

Multiple Independent Repeater control	Easy servicing
Up to 5 Duplexed Links	Intergrated Autopatch
Up to 4 different Remotes	Expand at any time
Recorded Natural Speech Telemetry	Programmable Scheduler
Programmable Macros	+10v to +14v Supply
Connect / Disconnect multiple Ports	Standard 5.25" Rack Mount
Internal Receiver Squelch processing	Card-Cage design

SPECIAL EVENT STATIONS

AUG 1-4

GRAND HAVEN, MI In conjunction with the annual Coast Guard Festival, the North Ottawa ARC will operate SE Station KE8DL from 1600Z-0000Z. Frequencies: 7.225/.250, 14.250/.300, 28.400/450. For certificate, send QSL card or equivalent with an SASE to ***KE8DL, 1815 Hillcrest, Grand Haven MI 49417.***

AUG 2-4

ST. LOUIS, MO "Youth in Ham Radio" is the theme of special event stations operating from three locations from 0001Z Aug. 3rd (Friday eve., Aug. 2nd, local time) until 2359Z Aug. 4th. Sammy Garrett AA0CR (1991 Westlink Report Young Ham of the Year) will operate from St. Louis MO; Mary Alestra KB2IGG (1990 Westlink Report Young Ham of the Year) will operate from New York City; Darrel Craig KK6BB, will operate from Fullerton CA. For QSL from any station, send QSL and contact number with a legal size SASE to ***AA8CR, PO Box 5832, St. Louis MO 63134.*** For a certificate for contacting all three stations, send 3 QSLs and 3 contact numbers with a 9x12 SASE. Frequencies: General/Novice portions of 40, 20, 17, 15 and 10 M (phone/CW)

AUG 10-11

BARNEGAT LIGHT, NJ The Old Barney ARC will operate SE Station W2OB from 1200-2300UTC Sat. and Sun. to celebrate National Lighthouse Day. Frequencies: CW-7040, 14040, 21040, 28040; SSB-7275, 14290, 21390, 28390; 146.835 repeater; 146.52 simplex. QSL via ***Joe Fleishinger NU2F, 75 Joshua Dr., Manahawkin NJ 08050.***

AUG 14-16

BRIDGEWATER, NJ The Somerset County Office of Emergency Management will operate WC2ADK 1400-0100Z each day to promote Amateur Radio, R.A.C.E.S. and Public Service at the annual 4-H Fair. HF on lower 25 kHz of General 80-10 meters, packet, ATV; visitors on 145.32 simplex. Send QSL and SASE to ***Somerset County OEM/4H, PO Box 3000, Somerville NJ 08876.***

AUG 15-16

YORKTOWN, VA The Southern Peninsula AR Klub will operate N4KZR between 1400Z and 2200Z on Aug 16, 17 and 18, to commemorate the 300th anniversary of the Founding of Yorktown VA, where the last battle of the American Revolution was fought. Phone operation is planned for the General portions of 80, 40, 20 and 15 meters, as well as the Novice 10 meter phone subband. For a commemorative certificate, QSL with SASE to ***M.C. Ellis, 300 Artillery Rd., Yorktown VA 23692.***

AUG 17-18

VANCOUVER, WA The Clark County ARC of Vancouver/Clark County WA, will sponsor station W7AIA to help celebrate the 32nd annual Antique Aircraft Fly-in and Display at Evergreen Flying Field (just East of Vancouver). Operating times will be from 1800-2359 UTC Sat.; 1800-2300 UTC Sun. Frequencies: Lower portion of General class part of the 40, 20, 15 meter bands and on or near 28.455 in the Novice/Tech portion of 10 meters (conditions permitting). For a commemorative certificate showing a 1917 Jenny, SASE only to ***CCARC, W7AIA, PO Box 1424, Vancouver WA 98668.***

MANITOWOC, WI The Mancorad RC of Manitowoc will operate W9DK from 1400-0000Z both days, from the WW II Submarine "Cobia" to celebrate Maritime Week. Frequencies: 7.250, 14.250, 21.350, 28.450. For certificate, send QSL and an SASE to ***Mancorad RC, PO Box 204, Manitowoc WI 54221-0204.***

AUG 28

TRANSITION NIGHT QSO PARTY for 135 CM The Eastern VHF/UHF Society urges amateurs to join together on the 135 CM band on the eve of Tues. Aug. 27th, to honor our 135 CM past and open our new band and opportunities. This event is to be known as "The 220 QSY QSO Party." Phase A extends from 2200-2400 GMT Aug. 27th (the last few hours before the change). The entire band, 220 to 225 MHz can be used. Phase B, from 0000-0400 GMT on Aug. 28th, is the first 4 hours after the change. Use of the entire band is allowed. For complete instructions and rules, contact ***Eastern VHF/UHF Society, Thomas J. Kirby W1EJ, 1 Meadow Knoll, PO Box 455, Pelham NH 03076.***

AUG 28-SEP 2

MOUNT PLEASANT, IA The Mt. Pleasant ARC will operate W0MME during the 42nd annual Midwest Old Threshers Reunion. Operation will be in the General portion of the 80-10 meter phone bands. Club members will monitor their 444.95 and 147.39 repeaters for those attending. For a QSL send an SASE to ***Dave Schneider WD8ENR, 507 Vine, Mt. Pleasant IA 52641-2846.***

RTTY LOOP

Packet or RTTY— Which is Better?

Packet, packet, packet . . . who's got the packet? As one of the newer forms of digital communication, packet circuits have certainly taken amateur circles by storm. Look around this magazine if you doubt this fact. Nevertheless, packet just might not be for everyone. To wit, consider this letter from Howard Evans W6IDS.

Howard writes, "I run a landline bulletin board named 'Amateur Radio CBCS' in Rancho Cordova, California. . . . What interests me is the number of users who have mentioned in the message areas (both local and national) that there seems to be a bit of disappointment regarding packet. It seems that the common line focuses on the apparent 'overload' of the packet systems in general.

"In the messages, I read comments about a pronounced delay in the forwarding/receipt of packet mail, and a marked comparison of RTTY to packet in through-put efficiency, with RTTY standing out.

"I have tested packet a couple of times and I must say I still prefer RTTY for general communications. I know the technology is in vogue, and it is chic to be a packeteer, but the amount of cost required to set up a reasonable packet station versus using a normal RTTY station, to me is not really justified. Of course, this is my own opinion, and frequently I am at odds with the vast majority on issues. I just can't get excited about packet, even if it is the in-thing to do today.

"For that reason, I am very disappointed at what appears to be a decline in active RTTY stations. Oh, I know they're there, but it *used* to be easy to find the critters lurking about, either monitoring for a call, or already engaged in a contact. I have spent some time tuning around, and it does seem to me that the general RTTY activity is declining. I think that is our loss.

"It is my contention that for HF communications, RTTY is the better way to go, overall. And yet, more people continue to focus on packet, only to reflect later on how 'slow' it is, and how entangled it has become in territorialism, intra-system bickering, and politics.

"I'm not trying to convince you of a particular point of view, rather I am trying to convey a sense of concern over what I perceive as an insufficient arrangement of priorities which has placed packet over RTTY."

AMTOR Hardware

Strong sentiments, Howard. I wonder how many others agree. Over the decade and a half this column has been running, I have seen many trends come and go. Will packet be just another fad, or does it have a true place in the scheme of things? I certainly look forward to other readers' thoughts and comments on this apparent schism in the digital world.

If packet has its critics, how about other non-Baudot forms of digital communication? Garry Hawkinson WA0RXB of Proctor, Minnesota, asks whether AMTOR is a software operation using a regular terminal unit, or if other hardware is required as well.

I guess the answer is yes . . . and no. One way to get onto AMTOR is with one of the newer multimode terminal units. These little wonders take care of all the work of encoding and decoding the various AMTOR modes, requiring only a dumb terminal on your end. We have mentioned AEA and Kantronics units in this column in the past, but other schemes are possible, including those that move all the smarts for the protocol into your computer, and rely only on the switching circuits of a terminal unit to complete the connection.

However, whatever technique you choose to get onto AMTOR, your transmitter and receiver have to be able to switch from transmit to receive and back again very quickly and cleanly. When using a mode which requests block-by-block confirmation, such as AMTOR or packet, efficient transmit/receive switching is a must.

One such problem was addressed in the July 1990 "RTTY Loop," in which a modification for the ICOM IC-740 transceiver was published. The transmit/receive timing was altered, allowing for more efficient and accurate AMTOR transmissions.

Hope this helps you sort out the alphabet soup of RTTY modes. We have covered AMTOR in depth in the past, and will continue to look into it in the future.

AMTOR and RTTY Bands

Once you get on AMTOR, though, the question of where to find QSOs comes up. This puzzles William Martin N7EU, who writes that he has ". . . been operating RTTY and AMTOR for about five years now, and wonders about the operating habits on this mode. Why is it most of the fellows seem to congregate on either 80 or 20 meters when there is so much other spectrum to try? It would seem to me that 40, and especially 30, meters would be an ideal band to use during the daytime period of operation. Since I don't have an 80 meter antenna yet, that leaves me only 20 meters to slug it out trying to make a contact on these two modes. On 20 it seems the boys really get crammed into a small portion of the band, making it difficult to make a contact. Thirty meters seems to be quiet most of the time, with a notable lack of activity on RTTY and AMTOR. Is it some unknown tradition that keeps the hams on RTTY in a certain band, or are they not interested in trying something new? Even on 10 meters, where you would expect some Novice to try RTTY, activity is nil.

"Maybe in one of your upcoming articles you could respond to my question and encourage some of the fellows to try 40 and 30 meters. After all, 30 is a CW/RTTY exclusive band, and seems well suited for this purpose. Is there a "calling" frequency on 30 that I am unaware of, or is everyone out to lunch on this one?

"I really enjoy the two modes, and find AMTOR to have a bit of an edge over RTTY at my power level (100 watts) and modest dipole antenna. I use the CP-1 with the MBA-TOR inserted into the back of the C-64, and find it quite adequate for my level of operating with these modes. I bought these items used, and they are quite adequate for the beginner.

The only disadvantage I can see is that this setup does not support packet. But I suspect that could be overlooked, considering the bargain price. You could always pick up a separate unit for packet later."

Well, William, I would say that the answer to your question about band use can be stated in one word: INERTIA! Hams congregate around these frequencies because that's where they started; they have always been there. Why those frequencies were chosen has to do with conditions no longer applicable, like crystal availability and VFO stability. That they were chosen remains quite applicable, because if you are looking for a QSO, you can tune where you know others are listening. And so the pile-up grows! There is nothing inherently wrong with staking out a new frequency, as long as it is in a valid RTTY band and you are not stomping on some net.

This is a good question, with valid arguments on both sides, and I look forward to hearing some other readers' comments on the topic.

As far as the hardware you are using, it is good to see that a shoestring system (by cost) does not have to be too limited. Great tips on the C-64 and accessories.

Check out those garage sales and flea markets, folks. After all, one man's trash may be another's terminal.

Drop me a note when you are on your terminal, or at your quill and pad. Either by mail, as these folks did, or on one of the online services: CompuServe (ppn 75036,2501) or Delphi (user name MARCWA3AJR). 73

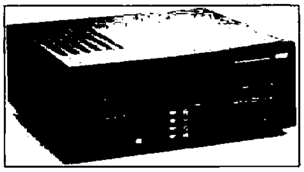
NEW PRODUCTS

Compiled by Hope Currier



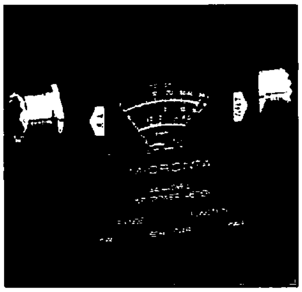
DRAKE

R. L. Drake's new R8 worldband shortwave receiver lets you hear world events as they happen. The R8 can be programmed to store up to 100 stations in memory for instant recall. A full complement of state-of-the-art filters and computer interface capability are also built in. It operates in the AM, LSB, USB, CW, RTTY and narrowband FM modes. The frequency range is 100 kHz–30 MHz, and covers all wortdband frequencies as well as most amateur bands. With an optional module, the R8 can also cover fire, police, public service broadcasts, and additional amateur bands in VHF (35–55 MHz, 108–174 MHz).

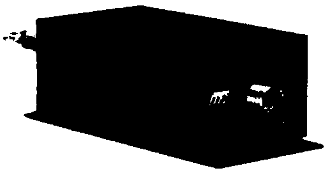
The suggested retail price for the R8 is $979. For more information, contact *R. L. Drake Company, P.O. Box 112, Miamisburg OH 45342; (513) 866-2421.* Or circle Reader Service No. 201.

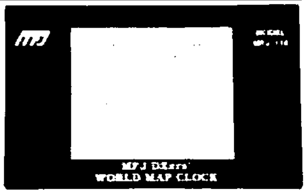
RADIO SHACK

Radio Shack is now offering the Micronta® Ham Radio SWR/Power Meter (cat. no. 19-320). This compact meter is ideal for optimizing antenna settings for hand-held transceivers as well as mobile or fixed ham radios. It is specifically designed for use on two popular amateur radio bands: 2m (144 MHz) and 70cm (440 MHz). The SWR/Power Meter's main features include: low insertion loss, enabling it to remain connected at all times; wide-range accuracy that lets the user measure power up to 60 watts; and a sealed diecast aluminum enclosure for durability.



The meter retails for $39.95 and is available at Radio Shack stores and participating dealers nationwide. For more information, contact *Radio Shack, 700 One Tandy Center, Fort Worth TX 76102; (817) 390-3300.* Or circle Reader Service No. 202.





MFJ

MFJ has released two new products: a balun box and a world map clock. Mount the **MFJ-912 W9INN Balun Box** outside the building and connect it with coax from your wide-range T-network tuner. The MFJ-912 will convert the unbalanced coax to the balanced ladder-line transmission line, functioning like an internal balun even though it's located away from the tuner. It retains the flexibility and efficiency of the ladder line without bringing the line into the shack.

The **MFJ-110 DXers' World Map Clock** shows the time and date at any QTH in the world, and also lets you see the location of your contact. Easy-to-use pushbuttons let you instantly move the display to a QTH in every time zone. The "recall" feature instantly moves the display back to local time. The clock shows the day of the week, month, date and year, and has an alarm.

The MFJ-912 W9INN Balun Box is $39.95; the MFJ-110 World Map Clock is $24.95. Both come with a one-year unconditional guarantee. Contact *MFJ Enterprises, Inc., P.O. Box 494, Mississippi State MS 39762; (601) 323-5869, (800) 647-1800, FAX (601) 323-6551, Telex 53 4590 MFJSTKV.* Or circle Reader Service No. 203.

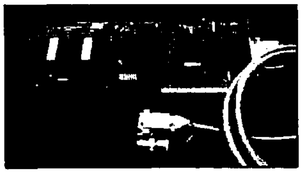
ICOM

ICOM has announced the new IC-2410A/H 144 and 440 MHz dual-band transceiver, which includes features such as simultaneous receive on the same band, microphone controllability and optional remote control. The IC-2410A/H is one of the smallest in its class: 5.5" (W) x 1.6" (H) x 6.9" (D), and weighing just three pounds. In addition to receiving two bands simultaneously, it will receive two frequencies on the same band.

The IC-2410A/H comes in two versions. The IC-2410A puts out a maximum of 25 watts on both UHF and VHF; maximum output power for the IC-2410H is 45 watts on VHF and 35 watts on UHF. Both versions offer high, medium and low power settings. A variety of operations can be controlled with the HM-56 DTMF hand microphone and optional UT-55 DTMF encoder/decoder.

For prices and more information, contact *ICOM America, 2380 116th Ave. N.E., P.O. Box C-90029, Bellevue WA 98009-9029; (206) 454-8155.* Or circle Reader Service number 209.

GRACILIS, INC.



Gracilis, Inc. has introduced the PackeTwin™ data system, a dual-channel PC interface card, integrated radio modem, and radio transceiver, with TCP/IP and AX.25 software for PC/XT/AT systems. Both PackeTwin channels can operate at conventional speeds of 1200–9600 baud. Additionally, one channel is capable of 1 Mb/sec operation with existing 56K radio modems as well as future higher speed developments. Both channels support RS-232, RS-422, and TTL. Radio modems are available for 1200, 2400 and 9600 bps. KA9Q's TCP/IP system software is also available with the system for packet network applications.

PackeTwin prices range from $199 to $599, depending on the configuration. For more information, contact *Gracilis, Inc., 623 Palace Street, Aurora IL 60506; (708) 897-9346* Or circle Reader Service No. 205.

RAI ENTERPRISES

RAI Enterprises has released a new PC software program, "Autolog Plus II." This program is a unique blend of a highly sophisticated station log and a fully programmable CW autokeyer. The log features four programmable on-screen time zone clocks, a 200-year calendar, a personal database and a notepad database to keep track of all personal data. Other features include a DXCC database, beam headings, QSL tracking, custom screen colors, on-screen "quick notes"to keep track of frequencies and calls in a pile-up, a programmable tracking cell with sort and print functions, and the ability to search and modify all log files. The only hardware requirements are a printer driver and 360K of free memory. An RS-232 interface is provided to drive the positive voltage CW key input of a solid-state receiver.

"Autolog Plus II," including the interface, sells for $45 and is available on both 5.25" and 3.5" floppies. For more information, contact *RAI Enterprises, 4508 N. 48th Drive, Phoenix AZ 85031.* Or circle Reader Service No. 204.

ALEXANDER BATTERIES

Alexander Batteries is offering several new made-in-the-USA batteries for Standard HX500 portable radios. The H26204 is a 7.5V/500 mAh nickel-cadmium battery. The H26205 is also rated at 7.5 VDC, but features longer run times and a 900 mAh capacity. The H26206 is 10 VDC, with a 425 mAh capacity; the H26207 is 10 VDC/700 mAh. Alexander's also has replacement batteries for the ICOM BP-83 and BP-84, and for Kenwood's TH-205A, TH-205AT, TH-215A, TH-215E, TH-315A, TH-415A and TH-415E radios.

For prices and more Information, contact *Alexander Batteries, P.O. Box 1508, Mason City IA 50401; (515) 423-8955, FAX (515) 423-1644.* Or circle Reader Service No. 207.

HI-RES COMMUNICATIONS

Hi-Res Communications has released the KWM2 video, packed full of detailed information regarding almost every facet of the KWM2 and spotlighting world-renowned Collins Radio expert Dennis Brothers. The video begins with basic tools and equipment, then Dennis takes you through tune-up and operation, troubleshooting and repair, modification identification and installation, and complete alignment.

For the price and more information, contact *Hi-Res Communications, Inc., Floyd Soo KF8AT, 18464 Ash Creek Drive, Mt. Clemens MI 48044-1240; (313) 228–1600*. Or circle Reader Service No. 206.

OPTOELECTRONICS

Optoelectronics is offering a new, free (to people involved with radio broadcasting and reception from sub-audio to 3 GHz) 16-page brochure describing the firm's newest hand-held and bench-top instruments. The brochure includes descriptions, technical data and useful tips on how to use frequency-finding handi-counters, universal counter-timers for lab and field, PC-based counters with Windows 3.0 for control and display, active preselector band-pass filters, antennas and accessories.

Contact *Optoelectronics Inc., 5821 NE 14th Avenue, Fort Lauderdale FL 33334; (800) 327-5912, (305) 771–2050.*

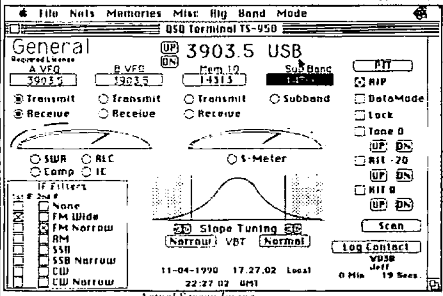
GIEHL ELECTRONICS

Giehl Electronics is offering two software enhancement kits, one for the Kenwood TS-940 and one for the Ten-Tec Paragon. The TS-940 kit features tunable memories that allow you to change the frequency of a memory channel using the main tuning knob, memory bank selection using the "UP" and "DOWN" keys, and easily-set kHz per revolution. The Paragon kit offers band registers that store the last-used frequency, mode, and filter for all bands 160 through 10 meters; a 10-minute timer that reminds you to ID your station, a single key band selector that makes QSYing fast, and many other enhancements. Both kits include a new software chip, complete documentation, and installation instructions.

The kits cost $72 each, plus $3 S & H. For more information, contact *Giehl Electronics, P.O. Box 18335, Cincinnati OH 45218*. Or circle Reader Service number 208.

QSO Comp-Troller
PC Control for Kenwood Rigs
New!

QSO Software proudly announces a second entry in quality ham radio software. QSO Comp-Troller offers complete PC control of Kenwood transceivers. The program is available for the Macintosh and MS-DOS (IBM Compatible) PCs with 64K EGA or VGA Graphics and a Microsoft® compatible mouse. QSO Comp-Troller is currently optimized for the Kenwood TS-950 transceiver, and will control all other RS-232 compatible Kenwood radios. Major functions included in the software are listed below. (Not all Kenwood models support every function)



Actual Screen Image

- Direct Keyboard Frequency Entry
- Text notes on each Memory
- Store and retrieve Memories to Disk
- Net Frequencies, notes, modes
- Required license & band limits
- Direct terminal emulation to Xcvr
- Sub Band receiver control
- Analog Multi-function and S-Meter
- Filter control
- Enhanced Scanning
- Automatic Logging
- GMT and Local on screen clock
- Slope and VBT tuning
- Graphical user interface with pull down menus and windowing

$99.95*

QSO Tutor
Study Aid for Amateur Exams

- Runs on IBM Personal Computers and compatibles or Macintoshes.
- Programs are available for all Amateur classes, Commercial Radio Telephone and Radar Endorsement. Sold separately.
- Work with the entire question pools (updated Nov. 1990), or study questions automatically selected by the program from your weakest areas.
- Includes full screen graphics & explanations on appropriate questions.
- Logs multiple study sessions and allows resuming at a later time.
- Creates randomly generated sample tests on-line or written on Epson/IBM or Macintosh graphics printers.

$29.95* per class
Mac® IBM®

* PA residents add 6%. Commercial cost is $39.95. Price includes shipping. Add $2 each for 3 1/2" IBM Disks

Public Domain disk also available. Contains excellent morse code tutor as well as other Ham Radio programs. Cost is $5 to cover materials and handling.

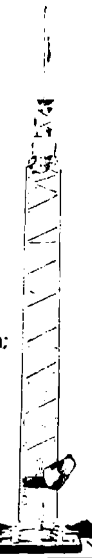
NOW YOU CAN AFFORD THE BEST!

Engineered for the Ham. The Finest in Crank-Up, Free-Standing or Guyed Towers from Tri-Ex. For over 30 years, the INDUSTRY standard-backed up with Defense and Aerospace technology.



MW SERIES
Self-supporting when attached at first section—will hold normal Tri-Band beam; 25', 33', 50', and 65' heights.

W SERIES
Aerodynamic tower designed to hold 9 square feet in a 50 MPH wind. 3 models at 36', 51', and 67' heights.

LM SERIES
"W" brace motorized tower. Holds large antenna loads. Models at 37', 54', and 70' heights.

TM SERIES
Tubular construction for larger antenna loads at 70', 90', and 100' heights. Free standing, with motorized operation.

Never Say Die

Continued from page 4

band and every mode, even a USA report which mentions *Radio Fun*. There's 20 pages of DX news!

About the only thing they don't seem to have is something along the lines of my endless editorials. Probably just as well.

It's a magazine packed with interesting information, aimed at rank beginners right on through to experts, with the latest news and circuits for every special interest.

For us to have a similar publication here we'd have to have about 300 pages of advertising. In order for the ham industry to support that much advertising they'd have to sell about five times as much ham gear as they do now. And that would mean that we'd have to have about four times as many active hams buying.

Yes, Japan is *that* far ahead of us. They're leaving us further and further behind in radio technology. It's a terrible blow to American pride to be left in the dust, fiddling around with CW and AM instead of exploring the microwaves.

Many Americans have suffered severe inferiority attacks as we've had to learn about quality, just-in-time production and other Japanese innovations. Now it's no-code and the Luddites are at it again.

Mini-Discs?

Sony, apparently unable to keep from challenging Matsushita (and losing), has announced a new recording technology, the mini-disc (MD). This was in response to Philips and Matsushita's Digital Compact Cassette (DCC) announcement in January.

So what's all this mean to amateur radio? Isn't this just of interest to music lovers? What do we care if the Japanese come up with something to replace the old audio cassette? It's about time anyway, right?

Since analog audio will soon be as dead as spark, our analog voice transmissions are going to be as antique as our beloved CW. Amateur radio is already so far behind today's technology that it's more a museum exhibit of the past than a practical communications service.

The only main drawback to digital audio is that it takes a much wider bandwidth than analog. Let me see some hands now. . . how many of you are prepared to get up in front of the group and explain the difference between analog and digital? Hmmm, not many hands. I was afraid of that.

What we do is pick up analog audio with a microphone. Then we set up an oscillator and have it trigger on a sampling circuit. The audio on our compact discs (CDs) is sampled 44,100 times a second. A 16-bit byte allows you to break down the sound into 65,000 sound levels and represent each by a number. This makes it possible to digitize frequencies from 0–20,000 Hz. . . up to half the sampling rate.

For ham use we might want to cut down to a 6 kHz sampling rate, which would give us 0–3,000 Hz, plenty for ham communications, yet too wide for most of our ham bands. This is where we want to start looking for ways to compact the data. We don't need anywhere near the 80 dB of dynamic range demanded by music, so we don't need music's 16-bit bytes. We can further cut down the data rate by using one-bit technology. This, instead of giving us the signal level from zero to 120 dB for every sample, just tells us whether the data number is lower or higher.

Okay, okay, it's complicated and, unless you've been keeping up with electronic technology, it's confusing. I just wanted to give you some idea of what's going on, not make you a digital scientist. Not that all this is beyond the grasp of an eleven year old. . . it just may be beyond the grasp of the average 59-year old ham who is bewildered about what a decibel actually is.

How long do you think Congress and the FCC are going to consider amateur radio a resource worthy of using our incredibly valuable bands if we keep falling further and further behind in technology? When will they stop and consider that maybe they don't need to provide quite so much museum space for us to insult and jam each other with our antique frequency-wasting technologies?

Up until about 25 years ago, amateurs were the leaders in communications technology. We pioneered NBFM, SSB, SSTV, RTTY and repeaters. Then everything almost completely stopped, leaving us with a hobby frozen in time at around 1963. Was it entirely a coincidence that the ARRL's Incentive Licensing proposal almost completely stopped the entry of young newcomers at this same time?

The increasing complexity of home construction using ICs didn't help. Oldtimers, brought up on tubes, got scared off by these little gadgets and the enormously complex circuits they could build with them. I still fondly remember building rigs with 815s, 826s, 832s and 813s. Sigh.

We *will* be going digital. It's just a question of if we have to wait for the Japanese to pioneer it for us. And as we are able to get our effective bandwidths down to a few hertz, we're going to find ourselves with wide open bands, with acres of space between contacts. . . more like 40m CW used to be 60 years ago. When Sony is able to knock out 80% of the data for hi-fi music and we're not able to hear the difference, the possibilities for ham communications quality voice are staggering.

If there's any real interest, we can start encouraging the writing of technical articles to help you cope with 1990's technology instead of living in the glorious 1940's technology as most of you have. Do you want to know more about digital audio?

Where Was Wayne?

A couple readers noticed my absence at the Dallas hamfest this year. I was over in Sedalia (MO) at the 11th International Scott Joplin Ragtime Festival—same weekend.

Since I've been pretty good at keeping my love of ragtime music a secret, it may surprise you that I would fly to Kansas City and then drive to Sedalia, just to hear ragtime music. Four glorious days (and nights) of ragtime, played by the world's top ragtime performers. . . nirvana.

It didn't hurt that two of my proteges were on the program this year for the first time. Scott Kirby, who I discovered in New Orleans, and Masanobu Ikemia, who I discovered at Sedalia last year, when he was just there as an attendee and not on the program. This year they were the big hits of the festival. . . with me sitting there glowing like a proud papa.

The festival drew about 350 attendees. I'll bet over a hundred of them played at one time or another in the after-hours ragtime jam sessions. . . which went on after the last evening concerts until as late as 6 a.m.

Last year I missed the last two days of the festival and flew up Saturday morning to give a talk at the Dallas hamfest. Only a couple dozen hams managed to break away from the flea market to listen, so I figured I'd do better to spend my time in Sedalia this year.

With two ragtime CDs already released on my Greener Pastures label and two more in the works. . . plus several more planned. . . the festival was a business investment too.

The lack of interest in my Dallas talk last year means either that most hams have had enough of me in my editorials—maybe too much—or that my talks have grown dull. Probably the latter. When I'm giving talks to hams I often feel like a cheerleader trying to get some enthusiasm from the inmates of a nursing home. When I ask for a showing of hands on how many in the audience have done *anything* of interest in amateur radio, a couple hands go up. The others all slouch down and look guilty.

I don't know what to say. It's like a bunch of starving people not quite able to touch the fabulous feast just beyond their reach. Have you tried OSCAR? RTTY? SSTV? These 20-year old technologies are still newfangled stuff to many hams. Even packet is new! Lordy. Whatcha done on 220? 900? 1296? 10 GHz? Maybe 50 MHz? They didn't need me as a cheerleader at Dallas this year, just as a funeral director.

One of the top American ragtime pianists is Dick Zimmerman. He's also a professional magician. Perhaps I should take some magic lessons from him and at least be able to entertain you old-timers with some magic, even if you don't want to hear about amateur radio.

Beating the Pile-Ups

If you're one of the thousands of ops devoting the rest of your life on this world to adding QRM to pile-ups chasing DX, I have a suggestion for you. Are you interested in a sneaky way to come out on top of the pile-ups, time after time?

Yes, I know, you already have a twelve-element beam and a ten kW linear. . . but so do all your competitors. You need something extra to make it through the QRM. It's odd that you haven't thought of this already, but then perhaps you haven't gone about solving this problem creatively. Your use of 10,000 watts is a hint that you tend to try and use brute force instead of brains to get your way. I hate to think about your family relations!

Okay, here's the edge which should make all the difference. Perhaps you've noticed that when you are transmitting, this tends to reduce your ability to hear what's happening on your channel. You know there are others in there, but you don't know exactly when they are transmitting or how much they've shifted off the frequency to try and be heard. You need a way to listen while you are talking.

Think how great it would be to be able to tune in and hear what's going on while you're calling! You'd be able to shift your frequency enough to be heard. You'd be able to wait until just the right moment and both jam your competitors so the rare DX station wouldn't be able to get their call. . . and sandwich your own call in the instant they shut up.

Now that I've told you what you need to do, I'm sure you're way ahead of me on how to do it. You need a remote receiver with a UHF link back. If it's a few miles away you'll be able to hear your own frequency and everything on it. We have enough garbage on 2m already, so put your intercom channel up on a higher band. You'll want to be able to remotely tune too. But that's easy with many modern receivers. Duck soup.

How about some construction articles on remote receiving systems?

Some Trivia

You might watch for "Mission of the Shark," a TV movie which is planned for broadcast around December 7th. I don't know how good the movie is, but it was shot on my old submarine, the *USS Drum* (SS-228), where I spent the war. The *Drum* is tied up in Battleship Park in Mobile, right next to the *Alabama*, in case you're down that way.

The movie stars Stacy Keach as Captain McVay, skipper of the *Indianapolis*, and Richard Thomas (John-Boy) as the ship's doctor. The *Indianapolis* was sunk by a Japanese submarine (played by the *Drum*), with Japanese-American actors. The cruiser was returning from having delivered an atomic bomb when it was sunk. Most of the crew survived the sinking, but were subsequently lost to sharks during their several days in the water because a Navy bureaucratic blunder prevented anyone looking for them.

American Cars

A couple Detroit union member readers got all upset over my put-down of American cars a few months ago. They told me how great American cars are now. Glad to hear that, even though it goes against everything I've experienced with rentals.

Thus it was with some interest that I read a report in *USA Today* on how U.S. car brands had improved their quality. Ford did the best, moving from the 18th to 8th best trouble-free brand. Out of the top eleven most trouble-free 1991 models, Pontiac placed 7th with their 6000. The other 10 were all foreign. In the trouble-free brand list the first seven were Lexus, Infiniti, Toyota, Mercedes, Acura, Honda, Subaru. . . and then Ford. You can't believe how distressed I am to be so wrong about American cars being clunkers. . . and my Detroit readers so right. Yes, I'm being sarcastic.

I don't suppose I've gotten you to read *The New Yorker* yet. Pity. Damned shame. They had a very interesting series on Chinatown recently that was worth reading. We seem to get mad at the Asians for coming over here and working incredibly hard to succeed. They aren't doing anything we can't do, they're just doing what we won't do. . . work.

Heck, a lot of hams are furious with me because I've worked so hard and have succeeded as a result. I was lucky to have good role models. My father worked hard, as did my grandfather, so it seemed normal to me. My grandfather was one of the founders of Citgo and my father helped start the first trans-Atlantic airline.

And how does this apply to amateur radio? Why am I bringing this up here? Because it's the same pattern I see in

amateur radio . . . we want to buy a rig, put up a manufactured beam and tower and work the world. Thousands of readers get mad at me when I suggest they actually learn electronic and radio theory. They are ready with a rope when I suggest that if they love the damned code so much they get good at it and prove it. They are starting the fire under the tar when I ask why they aren't on packet yet. Or OSCAR. Shoot the messenger. No, I'm not saying that American amateurs are a lazy, spoiled bunch of old-timers. I would never say that. You might say it, and I wouldn't deny it, but I'm certainly not going to say it.

Now, if our beloved and wealthy, uneducated and apparently unskilled Detroit car makers would make some extra effort to turn out cars without defects I'll be delighted to start checking my gourmet library for crow recipes. Perhaps cooked in Ripple?

Education

Did you miss the *Forbes* articles on education (May 27th)? Tsk. Milton Friedman (one of my heroes) said, "On the average it costs half as much to run anything privately as it does governmentally." Friedman says that our Ivy League colleges could cut their tuitions in half and still make money if they were exposed to the disciplines of the market rather than counting upon government subsidies and big private donors. He says "that universities are multiproduct enterprises. They produce three major products: schooling, research and monuments."

One shining success is the DeVry Institute of Technology, which provides a better education than even state colleges and at half the price. Yes, of course state educational authorities are fighting DeVry at every turn.

You know, if we could ever get Congress to allow private mail, we'd see twice as much service at half the cost. I'm old enough to remember two mail deliveries on weekdays and one on Saturdays . . . 2¢ first class mail and penny postcards.

IBM Dying?

Several years ago I predicted that IBM would eventually get killed by microcomputers. If you've been reading the business magazines you've been seeing IBM losing ground at an amazing rate. It's going to get worse.

Just as we've had a drop in the cost of computing of about a thousand to one in the last few years, the predictions are for a further million-fold rise in cost effectiveness within a few more years. To some degree IBM will be able to sell more of the lower priced computers, but there's no way they can sell a million times more.

IBM makes most of their really big bucks leasing software. The day of the three-thousand-dollar-a-month software lease is going away, right along with the need for $10 million computers.

Ten years ago I had to pay $15,000 for a 10 megabyte disk for my Prime minicomputer. Now they're building 40 megabyte drives into laptop portables.

So what does this mean to amateur radio? It means you ain't seen nothin' yet when it comes to computerized communications. It also means there are going to be an enormous number of opportunities to make big bucks with these new computer systems. Small entrepreneurial companies are going to have a field day with support products, running circles around the giants. Small companies can react much faster than big ones and drive them bananas.

Chip densities are moving towards billions of transistors on a single chip. That means they can put dozens of ultra-fast microcomputers all on one chip, working in tandem. This is going to force a similar expansion in communications. We have the choice of being spellbound, dumb bystanders . . . or plunging in and benefiting from the changes.

This explosion of communications is going to start making frequencies more valuable . . . particularly the microwaves. This means, in turn, that either we're up there earning our salt or we're going to gradually be left like our American Indians, on tiny, unwanted reservations.

Of course, if we had friends in high places, we might be able to stave off the inevitable. And how can we develop some friends in high places? The same way the big corporations who want our frequencies do . . . by bribing Congress. We have a democracy here, and that means you pay or you die. For as little as $100 each per year to your senator and representative (for their re-election funds), you'll help assure that you have a louder voice at that old radio spectrum pork barrel than Motorola, G.E. or Fujitsu.

73's To You, Too

Sevens and threes to ya good buddy, as the southern truck driver CBers put it. No, you don't have to puzzle about where "73" came from, you jist pay 'tention to your old Uncle Wayne, and he'll put ya straight.

It has to do with the very beginnings of amateur radio, away back near hunnert years ago. Some of the first hams were old Morse ops who'd worked on the telegraph lines out West. Out there a man's most precious possession was his gun, the good old Winchester 73, the gun which opened the West. The old ops used to end their messages with "I will you my 73." That got shortened, in true CB style, to "73," and meant "best wishes." You can tell if a ham is a lid if he pluralizes it. It ain't "best regardses," it's "73." Now aren't you glad you have old Uncle Wayne as a living link with the past . . . good buddy?

The next thing you'll be asking me where "88" came from. Git off the porch and let a cranky old man alone. Jeeze, these danged kids. Worse'n all those testy old men on CW bumbling along in 10 wpm horsecarts in a day of 25,000 wpm supersonic technology . . . and complaining about the fast drivers.

And while hams are fighting to keep bleeping at each other on CW, technology is moving ahead. In-flight phones in every seat are being tested on U.S. Air, Northwest and American Airlines. These phones use digital technology to encode the voice, plus they'll work with your laptop computer and even handle fax right there in your airline seat. You'll be able to make plane reservations, page friends on the ground, get stock quotes, read news headlines, look up flight schedules and so on. Now tell me again about how CW can get through when all else fails . . . I need to hear about that again to retain my failing faith.

Saudi Arabia

The Arabs, not just in Saudi Arabia but in all Arab countries, have one whale of a problem. And it's a problem which is going to make for wars for a long time to come.

If one asks how come the Arabs were way ahead in science and technology a thousand years ago and then stopped, I think the sad answer lies in their religion, Islam. Islam is against paying interest, which means that any fundamentalist Moslem society will never have the capital to grow. Few businesses can get started without borrowing money. We're talking about a religion which is anti-capitalist and thus dooms any country which is limited by it to failure . . . just as the communist countries failed.

And as if that weren't bad enough, Islam is also against technology. Science teachers in fundamentalist Islam countries find they must graduate Moslem students, whether they know anything or not. A ham visiting Saudi Arabia reports that the Aramco Saudi technicians spend their days in idle gossip and drinking tea. When something breaks they have to call an American supervisor.

I realize that it's blasphemous to question any aspect of a religion, even one which is a thousand years out of date and is keeping its believers in poverty . . . except for those families lucky enough to live on top of an oil field. I'm not suggesting that Moslems consider changing Islam, only that they stop being jealous of the wealth the rest of the world gains through technical education and using technology.

If you ever wondered why almost the only ham contacts you've made in the Middle East have been with Americans, now you know.

I've been interested in the growing number of articles about Kuwait and Saudi Arabia and their medieval societies . . . which we've just spent a few billion dollars rescuing from an old friend of theirs. I'm glad we lost fewer Americans doing it than we lose on a good night to crack-related killings.

I asked for some ham volunteers to follow our troops into Baghdad and set up some health and welfare stations. Several hams were ready to go. Alas, our troops stopped before entering Baghdad, a fact which General Schwartzkopf made plain was a bummer in his mind. It looks as though history has already backed him up. Anyway, I was very glad to see a few hams willing to pitch in to help out at their own cost.

Say, if you think I'm exaggerating about the hold religion has over there, just remember back to the Iranian mobs waving their fists at us on the evening news a few years ago. And the thousands of Iraqis doing ditto last year.

Free Cellular Calls

Well, free, if you don't get caught. I mentioned a couple years ago that most crooks were using cellular phones with altered serial numbered identification chips. The result is free phone calls . . . anywhere in the world.

A recent *Wall Street Journal* article tracked it all down to a computer hacker named Ken Bailey, who took a cellular phone apart and cracked the code. Ken, the *WSJ* claimed, was circumspect about it. He made bogus chips, but built in a security system so no one could make a copy of his chip and use it. They'd have to come to Ken for chips.

That worked fine until Ken's computer went on the fritz one night and he asked a friend, Bob Sutton, to help him fix it. In the process Bob came across the program and, being no fool, ran off a copy. Alas, he didn't copy the security check, so when he began popping chips for others, they had no problem making further copies. The cellular industry estimates they may lose around $600 million next year to these little buggers. Hmmm, now don't you wish you'd paid more attention when I told you to learn about computers a few years ago?

For those of my readers whose sense of humor rotted off through disuse, I'm not supportive of stealing phone services. But then I can't forget that America's wunderkind, Steve Jobs, got his start in business selling blue boxes to steal phone services from Ma Bell. And who's Jobs? He's the billionaire Apple computer alumnus. If it hadn't been for blue boxes and theft of services from Ma, we wouldn't have all those nice Macintoshes around. Who was it said crime doesn't pay? It wasn't the Mafia, that's for sure.

Zzzzzzzz . . .

Y'ever lay there awake, your mind churning, wishing you could saw zees? What would you pay for a dose of Old Doc Green's Insomnia Cure? Tell you what, if I give you the recipe and you find it works, all you owe me is one extra subscription to *73*. Fair enough?

Heck, this pound of cure is so powerful it'll put you to sleep in a dentist's waiting room. I use it to whup me into the Land of Nod on airplanes . . . something I never used to be able to do. We're talking industrial strength here.

No, it's not addictive. No, it doesn't have any bad side effects. No, it's not hypnotism . . . though that'll work pretty well too. Nope, what I've got is a system that's so simple and so incredibly obvious that you're going to be annoyed that you didn't think of it yourself.

Okay, I'll stop teasing you and let you in on the big secret . . . but don't forget the price. Once you've learned how to do this and you find it works like magic for you, which it will . . . heck, it can't fail . . . you owe me an extra *73* subscription. That means you're going to find another ham and get him or her to subscribe . . . or buy a gift subscription for a DX ham who can't afford one. If this is too hard a bargain, please stop reading right here. A deal is a deal, right?

Here's how it works. You're going to set up a habit pattern which will automatically put you to sleep. Yep, a simple Pavlovian stimulus/response deal. If you aren't up on Pavlov, it's because you have been poorly educated. And don't blame the schools, you're the main one responsible for your education, not our lousy schools.

From now on, every time you go to bed at night get into the same sleeping position. Find a comfortable position and use that every night. You're going to establish a habit. You're going to have your body recognize this position and start generating endorphins as soon as you assume the position.

No, that isn't all. That's not going to knock you out in an airline seat where you can't get into that position. But it's a way to get started with training your mind/body to go to sleep.

Step two is to choose a sound to repeat a few times every night as you go to sleep. Pick something euphonic like umm, oom, ooze, ahm, ease, or moo. Just say it a few times as you drift off to sleep. Hey, this isn't going to work if you try to use it to get to sleep when you are keyed up. Start breaking in the system when you are tired and will naturally go to sleep. We're building a habit pattern here.

After a few weeks the combination of falling asleep and the sound you've chosen as a mantra will be tied together and you'll find that your mantra will, more and more, help you fall asleep, even in circumstances where you'd ordinarily find it difficult or even impossible.

Notes from FN42

Field Day has come and gone, and I didn't make it to Colorado like I did last year. I did get an invitation, but I had to refuse because my schedule just wouldn't permit it, though I did make it to the High Country in July.

My big ham project for the summer was to make my one-legged 160m dipole into an honest two-legged 160m inverted vee. A very tall tree between my house and the property next door became available for the center support, so out came the bow and arrow, and it happened. What a difference!

It appears that we will start hearing from Australia again in the near future. David Horsfall VK2KFU has volunteered his services to bring us the news from Down Under. David is a member of the WIA, and during the last few years has served on Executive. He produces the weekly broadcasts for the WIA (VK2 Division). Welcome, David. We look forward to your contributions.—Arnie N1BAC

Roundup

Colombia The Colombian League of Radio Amateurs is sponsoring The Colombian Independence Day Contest. The contest will be held between 0000 and 2400 UTC on Saturday of the third weekend in July (July 20, 1991). For further information, contact: Liga Colombiana de Radioaficionados, The Colombian Independence Day Contest, P.O. Box 584, Bogota, Colombia, South America OR see the the 73BBS 73 International SIG (Colombian Independence Day Contest).

India VU2RG is a Silent Key. Who, might you ask, is VU2RG? He was in the limelight for many years, but certainly was not known for his work as a ham. VU2RG was Rajiv Gandhi, prime minister of India from 1984 to 1989, grandson of Hawaharlal Nehru, India's first prime minister, and son of Indira Gandhi, who ruled India for 15 years.

Gandhi, leader of the powerful Congress Party in India, was killed by a female suicide assassin as he was attempting to regain the position that he had lost in 1989.

The National Institute of Amateur Radio (NIAR) and the Bangalore Club Station, VU2NRJ, are sponsoring the Garden City Award. This award is continuous after March 1, 1991, and further information may be received from NIAR-HQ at Hyderabad, by writing NAGESH (VU2NUD), P.O. Box 5624, Bangalore-560010, India; OR you can download the information from the 73 International SIG (Garden City Award).

Japan From the JARL News: The Amateur Radio Festival, popularly known as Ham Fair, will be held on August 23, 24, and 25 this year under the auspices of JARL at the Tokyo International Trade Center Annex in Harumi, Tokyo, the same location as last year.

The theme this year is "Freshen-up Ham Life" and the catch-phrase is "Let's meet at Harumi under the glittering sunshine." A special event will be "Multi-band Know-how." Bring along a friend and join in the fun and frolic!

Switzerland From the International Telecommunication Union (ITU) Press Release: The most recent press release published in connection with the 23rd World Communication Day includes a feature by the United Nations Disaster Relief Office (UNDRO) on disaster preparedness and relief telecommunications. Included were the views of the Secretary-General of the League of Red Cross and Red Crescent Societies on the need to enhance the quality of information in disaster relief operations.

Key issues concerned taking a critical look at the quality, as well as the quantity, of information, facing up to the general failure of disaster agencies to communicate adequately with disaster victims; appreciating the mass media's involvement in disaster situations and ensuring that the media reflects the nature of disasters accurately.

Information scientists stress six attributes of useful information: clarity, accuracy, significance, timeliness, adequacy, and validity. Those dealing with communications from disaster areas must keep these attributes foremost in their thoughts if their information is to do any good.

USSR A quick note came from Serge UA9SAW on some of his DXpedition activities. He mentioned two DXpeditions: on 6–16 September 1989 as UL1K/UA9SAW in OBL024, and on 4–21 September 1990 as UH1E/UA9SAW from OBL044. Please QSL direct: Serge P. Klyushnikov, UA9SAW, P.O. Box 13, Gaj, Orenb. Obl., 462630, Russia, USSR (CCCP).

The following letter was received from Ken Carpenter KC4UG: "I always enjoy '73 International.' Since I have learned to speak Russian I have made many friends there, and receive a great deal of information about their ham activity. I plan to attend the hamfests in Leningrad and Omsk in August of this year. *[Say hello to Gene (Gennady) UA9MA and all the other hams from all of us at 73. We loved the awards he sent to us several years ago which were printed in this column.—Arnie]*

"I received the following from Serge EKØKBZ, 4K4/UAØKBZ and UAØKBZ. Serge operated EKØKBZ for the Big Circle Dog Sled expedition in 1990. He made over 6,000 contacts, but only received 200 QSLs because he couldn't receive his cards via Box 88 in Moscow. He is located in remote Cape Schmidt in the Arctic.

"His card is a beautiful three-part QSL with scenes of the sled teams in the arctic, the best I have seen from the USSR. He wants QSLs direct with two IRCs or, better yet, one green stamp. His address is: Serge Tsybizov UAØKBZ, P.O. Box DX, Cape Schmidt, Magadan Oblast, 686830 USSR.

"He also sent me information about the Soviet callbook. It has over 20,000 addresses and more than 400 local Russian QSL bureau addresses. It is available from: Giusppe Iannuzzi I8IYW, P.O. Box 5083, 80144 Napoli, Italy. The cost is $6 US, postpaid air-mail.

"The mail from Russia is getting slower each month, and a card via their bureau is almost impossible. At one time I was receiving mail from Russia in two weeks, but now it takes up to two months, air mail!

"I sent Mike UA9MI an MFJ packet TNC last year. He and Gene UA9MA are on HF packet from Omsk, Western Siberia. They are the only ones from that area on packet at this time. 73, Ken KC4UG."

Techsat I—Israel's First Hamsat

AMSAT-Israel, in cooperation with the Technion University of Haifa and the Asher Institute for Space Research, is building an amateur radio satellite. Most of those working on the bird are volunteers and students giving of their spare time in this on-going project to build smart satellites for the amateur radio community.

Techsat I is to support digital store-and-forward communications with an onboard packet BBS. The bird will fly in a polar low-earth-orbit (LEO) approximately 450 miles up. Because of the polar orbit (similar to the Microsats), everyone on earth will have a shot at the bird.

Two transmitters are planned for both telemetry and downlinking, and will work on 435 and 29 MHz. Uplink receivers will have five frequencies on 145 MHz, five channels on the 1260 MHz, and yet another five frequencies on 2400 MHz. As well as supporting PSK and FSK, the system will have FM AFSK capabilities, meaning that stations equipped with standard packet TNCs will be able to access the orbiting BBS. (PSK, Phase Shift Keying, which requires a special modem on the TNC, is much more efficient and effective for hamsat packeteering, but the FM AFSK mode is being provided to give "beginners" a taste!)

Hams involved in the project are Peleg Lapid 4X1GP, system designer, 'Oved Ben Aroya 4X4LS, software designer, and Shlomo Menuhin 4X1AS, IARC/AMSAT-IL coordinator.

Launch is planned for 1993 on an Ariane rocket. A scientific experiment, possibly in radio navigation, is also intended. Work at the present is still in the planning stage, but is reported to be in high gear. Wishes of Godspeed to the folks at the Technion University working on the project, with the hope that they will be successful in providing the international amateur community with another reliable hamsat. 73

Never Say Die

Continued from p. 74

Pavlov rang a bell every time he fed his dogs. After a while he found that just ringing the bell started their digestive juices flowing. So why not use this mechanism to help you go to sleep? It works! And it doesn't take very long to build this new and helpful habit pattern. There's no downside to this.

I used to hate long airline trips because I'd sit there wanting to sleep and just sit there hating every minute of it. Now I can doze off in seconds and wake up an hour later refreshed. Yes, I suppose I cheat a little. I do take along a sleeping mask to block out the bright lights or the movie. And I put in a pair of those foam yellow ear plugs to cut down the noise from the people talking across the aisle. And I take along an inflatable pillow that goes around my neck. The whole works fits into a small bag which I carry on with my laptop computer and reading material. The pillows are sold through several mail order houses for a few bucks and they work beautifully. I have the same travel package in my van so I can grab a few zees on trips. No, I'm not driving.

Most of us are able to get to sleep most of the time without any great problems. But every now and then we find that our mind is racing and we just lay there twisting and turning. This can be particularly frustrating if you've got an important day ahead and you really need that sleep.

Start building your sleep habit pattern so it'll be there when you need it. I've been taking afternoon naps for years. I find they make it possible for me to work smarter and harder late into the evening. This zonking system is priceless for getting me to sleep in a few seconds when I take a nap. I assume the position, say the word, and I'm out for almost exactly one hour.

By the way, you can train yourself to sleep exactly as long as you want too. The mind has an amazing ability to keep track of time. It works on a subconscious level. When I go to sleep I decide when I want to wake up...45 minutes, an hour...and bingo, I'm awake...usually within the exact minute. It works for long naps too. When I have to be up at a specific time and set my alarm, I almost always wake up about a half minute before the alarm goes off.

How much sleep should you get? That's a habit too. Some people get along fine on four or five hours. Others are habituated to eight to ten hours. I've got too much I want to do to waste time sleeping that isn't needed, so I generally go about five hours at night and one in the afternoon. Works for me.

Try my system and it'll work. Then start looking for a ham or prospective ham who needs a monthly shot of enthusiasm and get him (or her) to subscribe to *73*. I positively refuse to get upset if you find this so helpful that you feel obliged to wrestle up two subscriptions. 73

Keep on Switchin'

Last month, we were exploring switches and controls. Let's finish that up and move on to a new topic.

Microswitches really aren't all that small by today's standards. I suppose they must have seemed tiny compared to other switches when they were first introduced. We continue to call them microswitches, partly out of tradition, but also because a company called Microswitch, Inc., makes many of them.

The distinguishing characteristics of a microswitch are that it is rectangular and it is operated via a small plastic button near one end. Often, there is a lever arm mounted on the switch body, permitting a small force to operate the switch. This type of switch makes a distinctive "click" when it is pressed, and another when released.

The internal construction consists of several strips of metal arranged to provide a "snap" action which presses the contacts together. This action is what causes the click. I've seen a few microswitches with broken strips and a few with burned or corroded contacts. If there's no click, the strip is gone. If you hear the click but get no connection, suspect the contacts.

Although it is sometimes possible to break a switch open and clean burned contacts, it really isn't worth it. These switches are nearly all of one or two designs, and are easily replaced. In fact, Radio Shack sells two versions. And, of course, the mail order outlets have them. Don't waste your time—get a new switch!

You're Relay Switching Now

Relays, of course, are just magnetically operated switches. In my experience, they are among the most trouble-prone switching devices of all. Although coils can open now and then, the usual problem is poor connection at the switching contacts. The techniques for general contact cleaning I discussed last month apply here as well. Also, try soaking a piece of paper in contact cleaner (*not* the corrosive acidic kind) and pulling it between the contacts while you hold them closed. You may be surprised at how much gunk is deposited on the paper. In addition, check to make sure that the arms on which the contacts are mounted are not bent or sagging. Sometimes they just don't exert enough pressure.

I've had some frustrating times with relays. I've wasted more than a few hours trying to get an intermittent relay to work every time. Especially when low signal levels are involved, such as in TX/RX switching, the connection has to be very good, and some old relays just won't do it no matter how hard I work on them. If you run into this, try to get a new relay; it just isn't worth the misery to try to fix it.

By the way, always check the solder joints where the relay connects to the board. The heat-sinking effect of the large connections sometimes causes them to be soldered poorly at the factory. They may last for a few years, but they will eventually go. Unfortunately, the effect exactly mimics intermittent relay contacts, and it can drive you nuts.

Truly Micro

Among the smallest switches in use today are DIP switches, so-named because they conform to the Dual Inline Package specs for integrated circuits. Consequently, they look like ICs except that there's a row of switches on top. With the exception of some early CTCSS encoder applications, these switches will be found inside the rig, on the board.

They are intended for set-up parameters, so they don't see lots of switching action. Nonetheless, they occasionally can go bad. Some are slide switches while some are rockers, which are essentially toggle switches. In any case, these things are sealed, and they are just too small to mess with.

You can replace the slide type with a toggle unit, and vice versa, but always check *any* replacement with an ohmmeter, even if it has the same type of switches, to be sure the pinout is the same. Some DIPs may be wired quite differently and some may even have double-throw contacts.

Dits and Dahs

There is one kind of switch we hams are especially familiar with: the Morse code key. Its construction is obvious. Used with electronic keyer circuits and most solid-state rigs, the contacts handle only low power and rarely require more than a little cleaner-soaked paper pulled through them now and then.

Tube rigs (even those whose only tubes are in the driver and final stages), however, can put far more stress on the contacts, because they may be switching as much as 100 volts. If the rig won't key properly, or it sounds lousy on the air, check the key contacts before you dig into the circuitry. A good, low-resistance contact may be essential for proper transmitter operation, and even a few tens of ohms can cause trouble.

Louder, Please

Ah, potentiometers. I often wonder what sadist thought those up! No other kind of control causes as much trouble. Basically, a potentiometer (pot) is just a resistor. To make it variable, a wiper is rubbed across the resistance element. The closer it is to the element's connection, the lower the resistance.

Actually, pots have three connections, with one end of the element being ground and the other being the signal to be sampled. The wiper samples the signal and feeds the next circuit stage. When the pot is not working well, the symptoms can range from the obvious, such as a scratching sound in the audio, to the perplexing, such as an out-of-lock frequency synthesizer, depending upon the pot's intended function.

In fact, when you're faced with a difficult problem, it pays to check any pots or trimpots (small pots meant to be set and forgotten) with a scope to be sure they are not open. *Don't* turn them, though! Once you do, you have no way to set them back to their original positions.

Where's the Rub?

There are two basic kinds of pots: wire-wound and film. Wire-wounds, which have limited resolution (because the wiper can only make contact once per turn of the wire) as well as some inductance, are generally used only when their superior power-handling capabilities are required. The vast majority of pots is of the film variety.

In these units, the resistance element is a carbon-based film which is painted on a nonconductive substrate. The wiper, of course, rubs this film. Because the wiper rubs the resistance element, it is subject to the problem shared by other mechanical connections: poor contact. Unless the pot is being used in some power-handling situation, which is unlikely, the cause of the trouble is almost certainly *not* a burned contact! More likely, the problem is simple wearing away of the resistance element, or dirt or (gasp) cigarette residue clogging the works.

Unless the film is badly worn away, a shot of contact cleaner usually will restore the pot to fine condition. The trick is getting the spray into the pot. Most larger pots, such as volume and squelch controls, have slots near the solder contacts into which you can spray.

After spraying, rapidly twist the pot through its control range to disperse the cleaner and rub away the dirt. Although some smaller pots and trimpots can be sprayed, many are sealed. In that case, you are going to have to get a new part. Also, you'll be faced with the problem of setting it where it belongs. If you match the pointer visually with the old one, you should be close.

Of course, that won't work in the case of multi-turn trimpots, which have only a screw exposed. Unfortunately, you can't read the resistance of the wiper connection because that is what is not working in the first place! In any event, replacement of a trimpot is always going to entail readjustment. Luckily, trimpots rarely fail, because they rarely are moved.

Finally, before you suspect a pot, be sure it really is a pot! On some of the new rigs, the RIT, IF shift, and other controls may be optical encoders. This seems to be a trend in Japanese HF rigs, and it's a welcome one. The encoders are much more reliable than pots ever could be.

Well, I think that about does it for switches and controls. So now, let's turn our attention to a letter.

Dear Kaboom, *I have a Radio Shack HTX-100 mobile rig that I want to use as a base rig. I don't want to use a DC power supply. Is it possible to use a car battery at home, provided I charge it when it runs down? I tried to ask around, but I don't know any hams yet (I'm still studying for my license) and no one else seems to know.*

Signed,
Homin' In

Dear Homin,' Sure, why not? A charged car battery will run your 10-meter rig just fine. I can't imagine, though, why you would not prefer to use a power supply—it would be a lot easier. If you do use a car battery, be sure to properly ground the rig, just as you would if you were using a DC supply. And put a large electrolytic capacitor, say, a few thousand microfarad, in parallel with a 0.1 µf cap across the battery.

Of course, watch the electrolytic's polarity and be sure to use one rated for at least 25 volts. Also, beware of toxic (and possibly explosive) fumes from the battery. These things were never meant to be used indoors, and a spark, soldering iron, or cigarette lighter could set off the hydrogen they produce. The acid fumes can be toxic, too.

Finally, car batteries are not deep-cycle; they are meant for short starting periods followed by immediate recharge. If you run yours way down between charges, it will not live long. If you anticipate such use, get a deep-cycle marine battery, as it will be designed to withstand it. Best of luck and see you on the band!

Dear Kaboom, *My Yaesu FT-208R seems to have amnesia. It works fine, but when I shut it off, all the memories disappear. It's getting to be a pain to re-enter all my local repeaters. Where's my data going?*

Signed,
Forgetful

Dear Forgetful,

To that great databank in the sky, that's where! You have a classic case of "dead lithium battery-itis." '208s are old enough now that the batteries are finally starting to go. It's just a plain-Jane 3-volt lithium cell, but it has solder terminals on it, so you'd better order one from Yaesu, unless you know of a local source (I don't). The battery is located on the microprocessor board, just behind the speaker. You'll have to pull the board, so be careful not to break the wires going to the keypad. And naturally, be sure to get the polarity right—micros don't appreciate reversed voltage!

And see you all next month.

RDF Fights RFI

Even if you don't enjoy competitive transmitter hunting or search/rescue work, you will probably need to go DF-ing at some point. Most likely, your target will be some sort of non-ham RF interference (RFI).

Over the years, I have searched for dozens of noise sources, from aquarium heaters to gas oven thermostats. One of my most interesting (and frustrating) RFI adventures took place about two years ago in Stanton, California.

This story is true, but I'll leave out actual names, calls, and addresses. The victim (we'll call him W6XYZ) loved rag-chewing and daily nets on 75 meters. One day, a strange signal began to crowd him out. It was a very unstable carrier, moving up and down the band and occasionally disappearing. Most of the time, the signal was 20 dB over S9 and right on top of his favorite net frequency near 3900 kHz. By the time I got involved, W6XYZ's block had been checked out by the power and cable TV companies, who could not find the source of the signal in their lines.

Looking For Harmonics

The first rule of RFI-busting is to search on the highest practical frequency. At 80 and 40 meters, long power lines and other objects reradiate signals and distort RDF measurements. Null-type antennas are the norm. At VHF, gain antennas are practical, and long radiators are less common.

I set up a general coverage receiver and calibrated RF attenuator in W6XYZ's shack and tuned from 150 kHz up, making a chart of all RFI carriers by frequency and relative amplitude. There were a lot of them, but they all sounded different. The strongest (20 dB above the 3900 kHz spur) was at 3400 kHz.

Harmonics at varying levels (11 to 33 dB down) were present every 3400 kHz all the way up to 30 MHz, the top of the receiver range. I figured that the 15th harmonic at 51.05 MHz should be strong enough to detect. If so, my 6 meter T-hunt "Shrunken Quad" (see "Homing In" for January 1990) could DF the source.

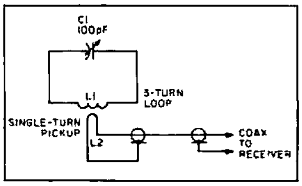

Figure 1. Schematic diagram of the 75/80 meter loop for RDF.

A few days later, my wife April and I were back with the van set up for 6 meter hunting. The 51 MHz harmonic dropped off rapidly as we drove away from W6XYZ's home. All the bearings pointed right back to his house. Using a Yaesu FT-690R and its whip, we sniffed around the house and found the source of the 51 MHz harmonic. It was the solar heating control unit in W6XYZ's own closet!

Gleefully, we turned off the controller and ran to the shack to check the HF bands. Sure enough, the noise at 3400 and its harmonics had stopped. In fact, the spectrum was very quiet—all except the signal at 3900 kHz. It was as strong as ever. Rats!

Building a Loop

So, the direction finding had to be done on 75 meters. We didn't have the time or the motivation to do anything fancy. All we needed was an indication of which way to go. A loop antenna was the clear choice.

The receiving loop (L1 in Figure 1) is three turns of #18 AWG solid enameled wire, resonated with a 100 pF air variable capacitor (C1). Signal snagged by this outer loop couples to the coax via single-turn inner loop L2. Inductive coupling works much better than direct coax connection to the outer loop, which would upset the balance and cause poor nulls.

Photo A shows the completed antenna on the T-hunt van. The frame is Class 125 (thin wall) PVC pipe, 3/4-inch trade size. That matches with my standard mast system for hunting on other bands (see "Homing In" for July 1989). Note that the coax bows slightly so it does not touch the bottom of L1.

To build this loop, cut the top and side PVC frame members and assemble them into a slip-type PVC cross-fitting. Bond them with PVC pipe glue. Use a 5/64-inch drill bit to make individual holes through the mast and cross pieces for the three large loop wires. Space the turns of the large loop about 3/16 inch apart. Holes for the large loop wires are 16 inches from the center of the cross, and holes for the inner pickup loop are eight inches out.

Tuning the antenna is easy—just connect it to the receiver and peak the background noise on the hunt frequency by adjusting C1 with an insulated tool. Keep yourself and any objects clear of the loop during tuning.

Check out your loop on a local (ground wave) signal before going RFI-hunting. The pattern of small (less than 0.08 wavelength) loops like this has two broad peaks (in the plane of the loop) and two sharp nulls (looking through the loop). The nulls are easiest to use and most accurate for RDF.

The ambiguous nulls 180 degrees apart would cause problems in a long distance T-hunt, but not in a neighborhood RFI search. Just take several "fixes" from well-spaced locations around the area and plot the lines of bearing on a map. They should intersect near the interference source. Follow the bearing lines and home in.

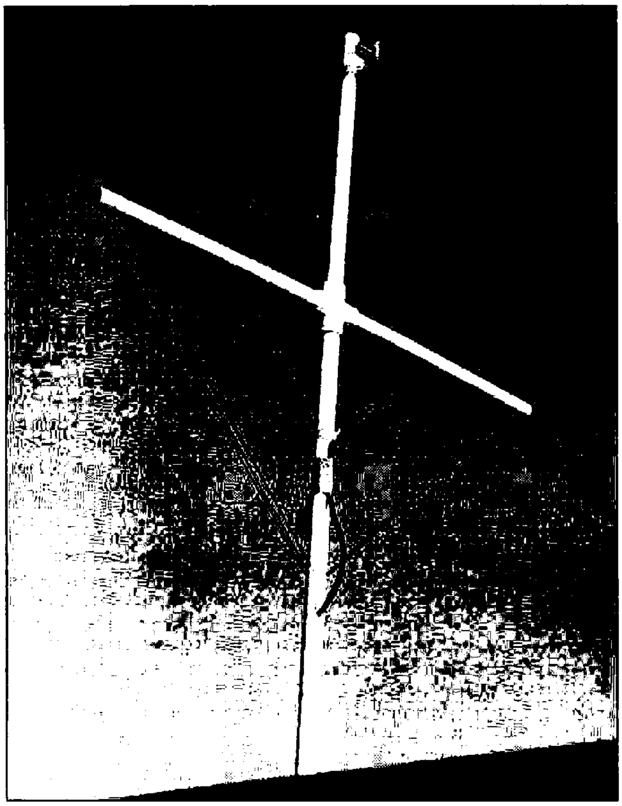

Photo A. Not fancy, but functional, this simple loop on a PVC pipe frame will ferret out interference sources on 75/80 meters.

If necessary, you can resolve the 180-degree ambiguity by using the directivity of a mobile whip on your vehicle. Typical 75-meter whip systems show higher S-meter readings in the direction of the greatest amount of ground plane. For example, if your whip is on the left rear bumper, it will give a slight amount of enhancement to signals coming from the right front.

Be sure to remove your 75-meter whip from the car while DFing with the loop. The proximity of a resonant whip causes inaccurate loop nulls. Similarly, avoid taking bearings when directly under power lines, etc.

If you expect to hunt very strong signals and your receiver does not have a wide range RF gain control, connect an RF attenuator between the antenna and the receiver. Do not transmit into the loop or attenuator. Unplug the mike and key to prevent accidents.

The loop will not give good nulls close-in if a long power line or the wiring of a house radiates the RFI. For example, let's say you are 200 feet away from the center of a radiating overhead power line 400 feet long. The difference in azimuth from the left end to the right end of the line is 90 degrees.

When you attempt to null the left end, the right end lies in the peak of the loop response. No matter which way you turn the loop in this case, there will be some signal to "fill" the null in the pattern. So, when you get too close to get good nulls, switch from the loop to a whip and move around, looking for the highest S-meter readings.

Closing In

A few days later, we went off to Stanton to snoop around with the loop. RDF bearings and S-meter readings showed the hottest area to be about two blocks away from W6XYZ in a cul-de-sac. The curbside signal was strongest in front of House A, and almost as strong in front of House B. Both were fed from one overhead power line in the rear.

House A's owner was not at home, so we rang the bell at House B. When I explained the problem, the family was very receptive and let me probe the back yard with a Sony ICF-7600 portable shortwave set. The power drop to the house and the breaker box were radiating plenty of 75 meter RF.

We found no obvious "hot spots" inside or outside. I asked if I could turn

off the House B main breaker for a minute. They consented, I flipped the breaker, and the noise continued in the portable receiver.

By now, the owner of House A was home, but he was not interested in W6XYZ's plight. "Hams cause all the TV interference problems," he said, "so I don't care if I cause a problem for a ham."

I told him I just wanted to check the incoming power line in his back yard.

"Come back with the Edison Company," he replied, and asked us to leave.

When I told W6XYZ about our experience, he began to despair. He said that he was thinking of selling his house and taking a long trip in his RV. I wasn't ready to give up yet.

To be absolutely sure that House A was the culprit, I did a "porch light survey," reading the signal strength of the 3900 KHz radiation from the front porch light wiring of every house in the neighborhood on the Sony receiver. Sure enough, the light at House A radiated 20 dB more signal than any other.

I tried one more time at the door of House A, this time with W6XYZ along.

Despite our best efforts at diplomacy, the owner would not let us into his house or yard, nor would he turn off any breakers for tests.

FCC Gets Involved

I gathered all the RDF and porch light data. Then I put together some maps of the neighborhood, showing how House A was clearly the RFI source. I wrote a cover letter to the engineer-in-charge of the Los Angeles area FCC office, detailing the problem. I pointed out that the 3900 KHz radiation from House A was so great as to be a violation of FCC Part 15, that the owner was uncooperative, and that FCC intervention was needed.

Less than two weeks after I sent the letter and data, the FCC sent a letter by certified mail to the owner of House A, telling him that he was in violation of Part 15 and had 15 days to correct the problem.

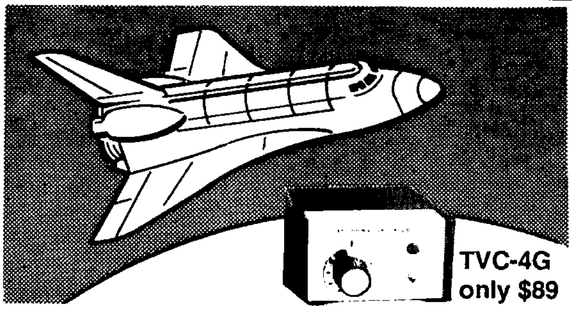
Apparently, that really lit his fuse. I heard that he promptly drove to the FCC office and railed against W6XYZ and me. Fortunately, the FCC stood firm.

From that point on, my information is secondhand. I heard that circuit breaker checks showed the QRM definitely came from House A, and that a bad power line ground and loose cable TV hardware were found and fixed. But the 3900 kHz radiation continued.

Two months later, I heard that an FCC engineer had located the RFI source in the house, and ordered it to be repaired. But by that time, W6XYZ had sold his house and was moving out.

Apparently, the malfunctioning device never got fixed. I drove down W6XYZ's old street last week, and heard an unstable carrier on 3900 kHz. If you like 75 meters and are thinking of buying a home in Stanton, call me first.

AMATEUR TELEVISION



SEE THE SPACE SHUTTLE VIDEO

Many ATV repeaters and individuals are retransmitting Space Shuttle Video & Audio from their TVRO's tuned to Satcom F2-R transponder 13. If it is being done in your area on 70 CM, all you need is one of our TVC-4G ATV 420-450 MHz downconveters, add any TV set to ch 3 and 70 CM antenna. Others may be retransmitting weather radar during significant storms. Once you get bitten by the ATV bug - and you will after seeing your first picture - show your shack with the TX70-1A companion ATV transmitter for only $279. It enables you to send back video from your camcorder, VCR or TV camera. ATV repeaters are springing up all over - check page 411 in the 90-91 ARRL Repeater Directory. Call for a copy of our complete 70, 33 & 23 CM ATV catalog.

ICOM™ R7000 Sweeping 1300 Channels/Min.

DELTACOMM™ 1.04 gives you a custom interface and optimized software that will not just control but will maximize the potential of your R7000. Spectrum log at speeds in excess of 1300 channels/min. while automatically generating a histogram of frequency/activity. Advanced priority channel monitoring and program control, by channel, of remote tape recorders during scanning. Here are a few (there are many more) examples of the advanced features DELTACOMM has to offer:

- Birdie log during frequency search automatically characterizes your R7000, then locks out those frequencies
- Auto histogram and scan file creation during spectrum log
- Scan file channel lock-out feature allows scanning around channels without removing that frequency from database
- Resume scan and maximum monitor values unique on each channel scanned
- Each frequency within a scan file has an area (40 characters wide) for channel information

- Auto frequency detection and storage during search and spectrum log
- User friendly installation program reduces need for DOS knowledge
- Full support of serial ports COM1-COM4
- On-screen HELP reduces need to refer to user manual
- REQUIREMENTS MS-DOS microcomputer with minimum 512K memory. DELTACOMM's performance is proportional to baud rate setting, style of display card and type of computer used

Simulated ATV Satellites

Students at Franklin Community High School (Franklin, Indiana) have a very exciting course offering. Each year juniors and seniors have the opportunity to take an Aerospace Technology Class (wish I had one of these when I was in school!) One particularly fascinating part of the course is the satellite simulation experiment. They get to design, build and test their own satellite.

This year, they decided to design a weather observation satellite. Since launch opportunities are limited, they elected to send their satellite to the edge of space using a weather balloon. To study cloud patterns, they incorporated a live TV camera and ATV transmitter so they could receive live images directly in their classroom mission control center. In addition, they designed two different radar reflectors to test their visibility on FAA radar screens.

Using components donated by Bob McAuliffe W9PRD from one of his pioneering ATV balloon experiments (June 1988), and with guidance from Chuck Crist WB9IHS and teacher Doug Craig, the students designed the satellite payload for maximum stability. They even performed wind tunnel tests and drop tests of the parachute recovery system. A series of classes were held to discuss the theory behind the system, go over the design goals, and then proceed to build the payload.

The payload consisted of a Wyman Research ATV transmitter, a Uniden VM-110 TV camera, a 2m FM transmitter with CW ID and a 10 meter CW beacon. Callsigns on the payload were: ATV—WB9IHS, 2m—W9PRD, and 10m—WB8ELK.

The components were mounted in a hexagonal styrofoam package with a swivel mounted on top. This aerodynamic design helped maintain a very stable camera platform for excellent ground imaging. One nice touch that I particularly enjoyed was the TV camera lens protector—half of a pair of sunglasses!

Liftoff

After thoroughly testing their satellite, the class was ready to fly. After a couple of weather delays, they were finally able to launch their balloon satellite at 1:15 p.m. EST on April 21. The students gathered around their ATV receive station and had a blast riding along with their balloon as it provided them with spectacular aerial views of their school as it was rapidly left behind.

The package disappeared into the clouds and nothing could be seen for awhile from the video camera. Soon the balloon system was above the clouds and they could observe the cloud tops from an ever increasing altitude. They now had a functioning weather satellite!

Quite a few area amateurs pitched in to help make this a successful event. Ron Pogue KD9QB and pilot Ken Jessup actually circled over the launchsite in a small plane and transmitted the takeoff through the Indianapolis ATV repeater. Dozens of midwestern hams checked into the tracking net (operated by Emmett K9YKX) with direction reports throughout the 2 hour flight. Excellent video (although of cloud tops) was reported over a several state area. Although the 2m beacon died at about 12,000 feet, it was heard as far away as Wisconsin!

Success!

The Indianapolis foxhunt group also provided their headings as they drove along under the payload. The students took these beam headings and plotted them on a large map of Indiana. They learned a lot about direction finding and were quite accurate in locating the package during its journey. After reaching 95,000 feet, their weather satellite could see a large area of Indiana below. At this point the balloon burst and the package parachuted back to Earth. Their map plots were so accurate that the chase plane was able to actually see the package as it was parachuting down and watch it land in an open field near a small road. The package had drifted just over 28 miles to the southeast to land near the towns of Westport and Alert.

The Indianapolis foxhunters were so close that they could see the circling plane. Larry Oaks WB9YAJ and Paul Bohrer W9DUU (two veteran balloon trackers) arrived at the scene just a few minutes after it landed.

The radar reflector experiment was successful. They actually flew *two* balloons. One of the reflectors (The Pizza Hut design—named for the sign it was designed around) flew on the main payload. The other reflector (a very large garbage can design) flew on a small, very slow-rising balloon that was launched at the same time as the weather satellite balloon. Both reflectors were made out of metallized Mylar. Controllers at the Indianapolis FAA center successfully tracked both balloons during their flights. Although there was no radio beacon on the small balloon, the controllers followed it almost to the Kentucky border. It was later found and returned!

Photographs from the Edge of Space

In addition to the live video experiment, I sent the students a 35mm film camera to attach to the side of their satellite. Even though the temperatures could drop down below −60 degrees, I hoped the camera would survive to take some really spectacular high definition color photos.

After browsing through the local photo store (Peterborough Camera), I found the perfect candidate, the Samsung AF-SLIM. This little gem is a full-featured pocket camera with a built-in autowinder and timer (30s, 60s or 10m). Another nice feature was a lens system that would pop out of its lens cover to take a picture and safely retract back into its protective cover (ideal for the harsh environment in the stratosphere!).

The class programmed the camera to take a photograph every 10 minutes during the flight. Since the balloon ascended at about 1000 feet per minute, they snatched a photo every 10,000 feet.

The results? Let me put it this way: When the photoprocessor in Indiana handed the photos back to Chuck

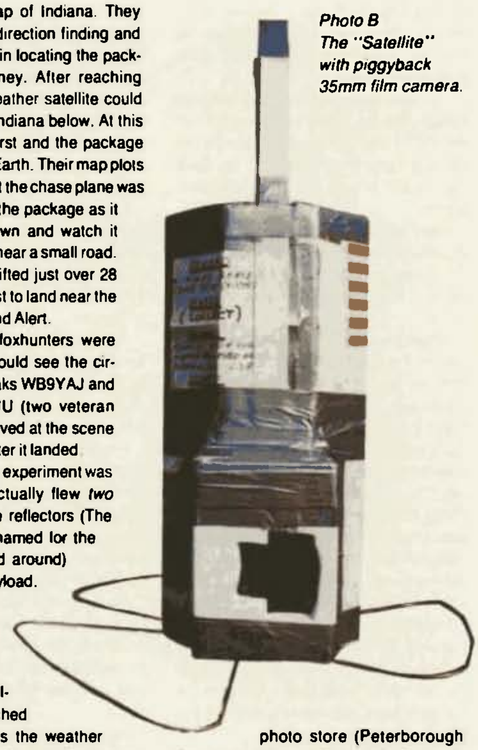

Photo B The "Satellite" with piggyback 35mm film camera.

Photo A. The Franklin Community High School Aerospace Technology Class (with satellite and radar reflectors in foreground).

Photo C. The automatic camera takes a surprise picture of balloon tracker Paul W9DUU shortly after landing.

Photo D. The Samsung AF-SLIM pocket camera can take the rigors of the stratosphere!

Photo E. 45,000 feet over Indiana.

Photo F. Stratospheric views from 75,000 feet (visibility over 350 miles). The blue layer is the Earth's atmosphere.

Photo G. The top altitude of 95,000 feet. The atmosphere is just a thin blue haze from this vantage point at the very edge of space!

WB9IHS, he said, "How'd you take these pictures? From a spacecraft?" "*. . . Well, as a matter of fact . . .*". See photos E through G for the spectacular results. Photo E was taken at 45,000 feet, Photo F at 75,000 feet and Photo G at the top altitude of 95,000 feet.

The Next Step?

The Aerospace class plans another experiment this October. This time they will design a communications satellite. At least a dozen schools across the midwest plan to use this balloon satellite to communicate with each other via a cross-band FM repeater system. The cross-band repeater will be unique in that the audio uplink to the satellite will be on 2 meters, but the downlink will be on both the sound subcarrier and on-carrier of an ATV transmitter (with live TV camera). That way, even if one of the schools doesn't have an ATV receive setup, they can tune in to the ATV center carrier on an FM receiver.

RANDOM OUTPUT

David Cassidy N1GPH

Cleveland Calling

She said she lived in the Cleveland area. She called the *73* offices to ask a few questions, offer a few suggestions and just to chat about amateur radio. (You'd be surprised at how many calls I get in a week from people who just want to talk about radio. They hardly ever ask for me by name, but Rose at the switchboard puts them through to me when she can't figure out who else to forward their calls to.)

We talked for a while, and I got to know a little about her. Her story is quite typical: a 1x3 callsign, licensed for almost 30 years, inactive for most of those 30 years (though always renewing the license), recently getting back into the radio hobby. She was stymied by the incredible changes in the last fifteen-or-so years. Shirt pocket-sized HTs, HF rigs costing a third of your annual salary that do everything but print the QSL card and lick the stamp, Novice voice privileges, the WARC bands, packet—all brand new to her. So many changes. So many things to catch up on.

She told me she had even lost her head and, in a fit of high tech euphoria, actually gone out and bought herself a computer.

She was easy to talk to. As good a listener as she was a talker, I found the conversation lengthening effortlessly to 10, 15, 20 minutes—sort of like those nice QSOs you have every once in a while when you actually feel you've gotten to know someone and maybe even made a new friend.

"Do you want to know the biggest change I've noticed?" she asked, as we got ready to say our goodbyes. "I can't believe the foul language and just plain rudeness you hear on the bands now. Don't these hams realize that there are people all over the world listening to them? Why isn't the FCC doing something about this?"

I explained that the FCC simply doesn't have the budget, staff or interest in acting as amateur radio's hall monitor. I told her that since amateur radio was supposed to be self-policing, it was up to her and me—and all licensed amateurs—to regulate ourselves.

There was a long silence, and I could feel the mood of the conversation turn, not to anger or self-righteous indignation, but to sadness. She and I, both of us licensed since our early teens, sharing a melancholy recollection of how things used to be.

"Do you remember when people were courteous to each other on the ham bands?" she asked.

I said yes.

"Do you remember when people actually talked to each other and got to know each other, instead of all this 'you're 5 and 9, thanks for the QSO' business?"

"Yes."

"Do you remember when you never EVER heard foul language or dirty jokes on the bands?"

"Yes, it wasn't all that long ago."

"So . . . what happened?"

The pleading in her voice indicated that this wasn't a rhetorical question. She really wanted an answer. I didn't have one for her.

"Couldn't you write something about this? You could ask people to clean up their acts. Write articles about how average hams could help clean up the bands."

I told her to go back over the last twelve issues and read Wayne's columns. He's addressed these issues over and over again.

"Don't you understand the power you have?" she asked. "Don't you understand that the ham magazines could get together and really help make amateur radio better by pointing out some of these problems?"

She became more and more insistant—more and more desperate. The conversation continued along the same lines for many minutes. The more she asked "why," the worse I felt for not being able to give her a satisfactory answer. I didn't know what to tell her, except that at least we could set a good example for newcomers by our own courteous practices. She told me she did indeed make a point of scanning the Novice portion of 10 meters and answering those young voices calling "CQ." I thanked her for that, and told her to keep it up.

The conversation was over. I could tell we both hung up with a sour feeling in our hearts: Hers for not getting the answers she was searching for, mine for not being able to provide those answers.

I sat at my desk, staring at my phone and thinking about what she had said. She had told me I had "power." She had used the old pen being mightier than the sword cliche and asked me—pleaded with me—to do something to change people's attitudes. We had both remembered when the ham bands were an island of courtesy in a brusque and brash world. She had hoped I could tell her how to return to this time. I could not. I do not have the "power" she thinks I have. Neither does Alan Dorhoffer . . . nor Dave Sumner . . . nor Wayne Green himself.

How can we get people to remember that if we do not clean up our own messes, pretty soon we will all be living in the same garbage pit?

Do any of you have an answer? There's a woman in Cleveland who needs to know. 73

Winding Down

As I write (around the end of April), we have seen the solar flux dive from a 300+ value to a 130+ value in less than a month! Yes, Cycle 22 is on its way down. In August you can expect some good conditions and some fair-to-poor conditions as we move from summer to autumn. See the calendar below.

The poorest days for DX on the HF bands will be approximately the 5th–8th; the 16th–21st; and the 24th–27th. Otherwise, you may expect decent worldwide conditions—unless, of course, we get some unexpected solar flares in between these dates!

Ordinarily, the flares occur near or on the dates given as poor, so don't be too concerned about the other days . . . but be aware that Old Sol is often unpredictable.

The HF bands from 10 through 20 meters will be open on many days until well after local dark, and during the day you can expect everything from short skip to long skip. Long path DXing can take place in the early morning hours just after sunrise, and occasionally just after dark.

Use the band-time-country chart to plan your operating on the HF bands, and use the daily forecast to pick the best days for your efforts.

I've noticed plenty of times that stations will make futile calls for DX at times, and on days, when there is no hope of raising anyone! Perhaps that is because these operators are totally unaware of the forecasts or the reasons behind them. Don't try harder—just smarter! See you next month, and meanwhile, for the most up-to-date conditions in the ionosphere, listen to WWV at 18 minutes after any hour. 73

Manuscripts Contributions in the form of manuscripts with drawings and/or photographs are welcome and will be considered for possible publication. We can assume no responsibility for loss or damage to any material. Please enclose a stamped, self-addressed envelope with each submission. Payment for the use of any unsolicited material will be made upon puolication. A premium will be paid for accepted articles that have been submitted electronically (CompuServe ppn 70310,775 or MCI Mail "WGEPUB" or GEnie address "MAG73") or on disk as an IBM-compatible ASCII file. You can also contact us at the 73 BBS at (603) 525-4438, 300 or 1200 baud, 8 data bits, no parity, one stop bit. All contributions should be directed to the *73* editorial offices. "How to Write for *73*" guidelines are available upon request. US citizens must include their social security number with submitted manuscripts.

73 Amateur Radio Today (ISSN 1052-2522) is published monthly by WGE Publishing, Inc., WGE Center, Forest Road, Hancock, New Hampshire 03449. Entire contents ©1991 by WGE Publishing, Inc. No part of this publication may be reproduced without written permission from the publisher. For Subscription Services write *73 Amateur Radio Today*, PO Box 58866, Boulder, CO 80322-8866, or call 1-800-289-0388. In CO call 1-303-447-9330. The subscription rate is: one year $24.97; two years $39.97. Additional postage for Canada is $7.00 plus $2.24 GST, and for other foreign countries, $19.00 surface and $37.00 airmail per year. All foreign orders must be accompanied by payment ls US funds. Second class postage paid at Hancock, New Hampshire, and at additional mailing offices. Canadian second class mail registration number 9566. Canadian GST Registration #125393314. Microfilm Edition—University Microfilm, Ann Arbor, MI 48106. Postmaster: send address changes to *73 Amateur Radio Today*, PO Box 58866, Boulder, CO 80322-8866.

Audit Bureau of Circulations (ABC) membership applied for.

Contract: By being so nosey as to read this teeny-tiny print, you have just become legally obligated to *73 Amateur Radio Today* for the amount of one subscription. Yup, that's all. Just one measly subscription and you're off the hook for a whole thirty days. If you can't convince a friend to cough up a lousy $19.97 for 12 issues of the best amateur radio magazine out there, then why not buy a gift subscription for a deserving Novice, Tech, potential ham, library or school radio club?

Number 1 on your Feedback card

NEVER SAY DIE

Wayne Green W2NSD/1

Are You Free?

America, "the land of the free," right? We brag to the world about our freedom and we try to convince other countries to follow our leadership. Freedom of religion. Freedom of choice. Political freedom.

Hmmm, yes, to some degree. But I have a problem with my concept of freedom and the actuality of living in America. For instance, it used to bother me greatly that as a child I had so few rights. The government said I had to go to school. They didn't say here are the reasons why you'll benefit from going to school so it's a good idea and we're making it available to you. They said either you go to school or you go to prison. Now let's run through that land of the free bit again.

During WWII the government said we'd like you to fight. They didn't put it exactly that way. It was more like you have a choice of fighting or going to prison. Yes, it's a choice. So as a kid I went to school to avoid prison, not to get an education. And I went to war and was fairly directly involved with killing thousands of Japanese (they were Japs then).

All this came to mind when I got to thinking about why I've always been entrepreneurially inclined. It's that freedom thing. When I worked for others, I found I had to give up a good deal of my freedom. When you're free you hold your head up a little higher. . . and having your own business gives you much more of an opportunity to be free.

Being an entrepreneur opens up this opportunity. It also at least gives you a chance at hitting the jackpot. . . something working for others isn't likely to do. Not many entrepreneurs make it big. Indeed, very few entrepreneurs start their own businesses with the main goal of making a lot of money.

It irks me that so much of our government is devoted to taking away my freedoms. . . that so many laws limit my freedom. And I'm not talking about the freedom to go out and bop people. You may or may not enjoy the cartoons in *Playboy*, but you should at least read their regular column on government assaults on our personal freedoms.

All this came to mind when I was considering encouraging you to give entrepreneurialism a try. . . maybe in your spare time. Freedom does have its costs. You have to work for it. You have to be responsible for yourself, which is a responsibility many people will go to lengths to avoid. One good aspect of slavery is that someone else is responsible. You have to do what they say, when they say. But in exchange you normally get food, shelter and a retirement plan.

If you're interested in giving freedom a try and would enjoy working part time out of your home, I'm planning on looking for some sales and service help in your area. Selling what? Magazines and compact discs mostly.

You'll need a car and some experience in bookkeeping and selling. And you'll want to be fairly near an urban area where there are record, musical instrument, hi-fi, and book stores. I'd prefer it if you don't smoke (so you won't be sick so much of the time or drop dead just as you get your territory really cooking). I don't care how old you are, what race, color or sex. Oh yes, one more thing . . . you need to be nuts about music. I don't want to hear from people who are just looking to make a buck. I need people who will have the time of their lives and be in love with the product.

What's involved is the distribution of about 10 monthly magazines and 2,500 compact disc titles (so far). It hasn't much to do with amateur radio right now, but if we can get the ham industry growing a bit, we might be able to expand into that. The no-code license seems to be doing better than I expected, so I'm optimistic. But for now the music business is roaring along—so why not ride the faster horse? It's an $8 billion American market and growing fast. . . and I publish the leading magazines in the field.

Well, I could go on at great length, painting beautiful pictures of wealth and happiness, but I don't want to interfere with your normal depression or trigger an outburst from the totally defeated contingent who somehow blunder into my editorials.

The time was when being a rep for amateur equipment was a great job. That was back before the Great Ham Crash of 1964 when we had over 850 ham stores around the country and they were selling several times as much ham gear as today.

Heath was the last of the old-time ham equipment companies. When they stopped advertising in *73* I knew that was the beginning of the end. Remember their old Hot Water rigs? They were great little single-band SSB rigs which sold for $100! I used 'em in a number of rare countries and handled huge pile-ups. Alas, without the Japanese market, which is about five times the size of ours, it's almost impossible to stay in the ham business these days.

Well, it's your spare time, so you invest it the way you think best. If you're working for someone else and not so happy with your work that you can hardly wait to get in every morning, you might give some thought to being an entrepreneur. . . perhaps starting a small business at home in a field you enjoy.

Or you can use your time to call in on the net every night and trade jibes with friends. I did that for a couple years, so I know it's fun and kinda addicting. It's like standing around the corner with your gang . . . and about as productive. Bill and Olga, Homer, Leo and I had a great time on 75m.

Well, in truth I did a little more than chitchat on the net. I also was building some nice VHF gear and working 2m DX from New England mountaintops. I ran up a pretty good DX score too. . . won the ARRL Sweepstakes for my section. . . all while going to college, running a sandwich and laundry business, starting the campus broadcasting system (WRPI) and stuff like that, plus a romance which will be a feature chapter in my memoirs.

Even if you're retired you've still got a few years to start and run your own business. You'll be having so much fun you won't have time to die. And you'll be making so much money you won't even gripe about the *73* subscription price.

I'm going to build a national sales force to rep a bunch of music magazines and several hundred independent record companies, so if you have the time and a whole lot of interest let me know. I'm going to give hams first crack at what could turn out to be a pretty good business. If you think this is for you, I can send you the gory details.

Making Your Club Work

The only real organizations in our hobby are our local radio clubs, so it's important that we make them do as much as possible to help our hobby survive. . . perhaps even grow. And that means making meetings fun and recruiting potential new hams.

Let's mull over this fun thing first. Having been to more ham club meetings than you, by a wide margin, let me assure you that pitifully few of them qualify as candidates for fun evenings . . . except of course, ahem, if I'm on the program. And that's fun for me, even if it isn't for you.

If you're the president of a radio club it's highly unlikely you're going to be reading this. Most clubs seem to be firmly in the grips of old fogies. . . who really hate my editorials. They disagree with what little of them they can understand. And, having had their sense of humor atrophy from disuse, they try to take me seriously. . . which isn't going to get anyone anywhere.

Alas, they bring their old-fogy grumpiness to meetings to share with any ham newcomers who have the guts to chance trying the club. Many club meetings, having been taken over by these fogies, are exercises in group grumps. They bitch about the lousy bands. They gripe about no-coders. They kvetch about how expensive rigs are these days. . . somehow forgetting that their old nickel ice cream cones are now $1.62, with tax. Their diet tends more to bran and prune juice, so maybe they haven't bought a cone lately.

If the shoe doesn't fit with your club, be thankful. From my personal experience...and from hundreds of recent reader letters. . . I'm not exaggerating.

If you want to build up attendance at your club you have to make the meetings fun. This means making sure that your members keep an eye out for any newcomers and make a special effort to shake hands and rag-chew. Ever been rushed by a fraternity? They have a team waiting at the door which shakes your hand and guides you into the clubroom and gets you started talking.

The executive committee should take care of 90% of the club business so you can keep the business part of the meeting mercifully short. The common denominator is amateur radio, so get right on to talking about that. What's doing on 6m? How's 10m doing? Anyone work some good DX on 75 or 160? What's happening with packet? ATV? SSTV? How about high-speed CW?

Has anyone bought any new gear they can talk about? Anyone built something they've brought in to show? Is there a hamfest within driving distance where you can organize a convoy? How about a group flight to Dayton next year, complete with a group picture by the big hamfest sign?

Any contests coming up where the club can participate? Tried fox hunting on Sundays yet? How about a club video showing what interesting things your members are doing? Are your DXers all connected via a repeater so they won't miss any rare ones?

Have you any tech sessions before

Continued on page 87

QRX . . .

EDITED BY LINDA RENEAU KA1UKM

ARRL Petition for 216-220 MHz

The ARRL has filed a petition with the FCC to request an Amateur Radio Service secondary allocation at 216-220 MHz. The massive, half-inch proposal weighs a full pound. Comprised of four sections and three exhibits, it is well-documented and impressive. The ARRL states that "This allocation would provide re-accommodation for those present and future wideband data intercity links and other point-to-point fixed amateur stations. . . displaced [last August] from the 220-222 MHz band as a result of the reallocation of that segment in Docket 87-14."

The League believes that amateurs can peacefully co-exist with present and future users of the band. The Commission may also have this belief, since it was they who initially suggested this approach. The 216-220 MHz band is currently allocated to various mobile and fixed services. The ARRL petition asks that Part 97.303(e) be changed to read: ". . . the segment 216-220 MHz shall be used only for point-to-point amateur fixed operation. No amateur station operating in that segment shall cause harmful interference to, nor is protected from interference from, maritime mobile stations, fixed stations, or other mobile licensees operating in the band. Nor shall harmful interference to broadcast television reception be created from operating in that band. Prior to commencement of amateur operation in that band, amateur stations are cautioned to contact a database administrator for the Amateur Radio Service for frequency recommendations in order to avoid interference to licensees of other services. The Licensee of the amateur station must make all necessary adjustments, including termination of all transmissions, if harmful interference is caused."

Part 97.313(d) would also be changed to read: "In the 216-220 MHz segment of the 1.25m band, no station may transmit with a transmitter power exceeding 50W PEP." TNX *W5YI Report, Vol. 13, Issue #13.*

PRB-1 Validity Questioned

A federal appeals court has ruled that ham radio operators are not entitled to absolute protection by FCC statutes enacted to give them special rights to have antennas. In doing so, the court has brought the constitutionality of PRB-1 into question. On June 19, 1991, the 9th Circuit Court of Appeals for Northern California denied a claim by a Burlingame, California resident, Vernon Howard W6ERS, who argued that federal law guaranteed his right to build a 51-foot antenna tower in his back yard, and his right to use it freely to communicate with fellow hams worldwide. The three-judge appeals panel rejected Howard's contention that the city violated his free speech rights.

According to Howard, his initial application for a variance was turned down in 1987 after what he feels was an unfair hearing by the Burlingame planning board. W6ERS said that forced him to take the city to federal district court. The judge ruled in his favor, based on PRB-1 guarantees, so Howard installed his tower and antenna, then went about trying to recover the $25,000 he had spent in court costs and legal fees. When this failed, W6ERS took legal action on his demand for reimbursement. It appears that this action resulted in the city deciding to let the appeals court make a final determination based solely on the merits of the issues.

The court ruled that FCC regulations entitle ham radio operators only to a "fair consideration by city officials" of their applications to build antennas. Cities and municipalities are still required to make a "reasonable effort consistent with local zoning goals to accommodate the projects," as mandated by PRB-1, but at the same time stating that esthetics can be considered in making a determination of whether to allow the erection of such structures.

The decision upholds the earlier ruling of a federal district judge in San Francisco who validated Burlingame's authority to regulate the heights of back yard antennas over 25 feet high, and cites the 4th Circuit U.S. Court of Appeals decision in Williams vs City of Columbia, South Carolina, where the court said the city had complied with PRB-1 by allowing a 17-foot high antenna. These decisions questioning the constitutionality of PRB-1 are at odds with other federal appeals courts which have agreed with the FCC and the amateur radio community on PRB-1's constitutionality.

Eventually, PRB-1's validity will probably have to be determined by the United States Supreme Court. According to one attorney, the Howard vs Burlingame findings are damaging for ham radio. The case will appear as a precedent-setting decision of the court that is just one level below the Supreme Court. It will also be published in the *Federal Register,* which is kept in virtually every law library in the country. Every city attorney who reads it will learn that a city has the legal right to flatly turn down any antenna permit request despite PRB-1. TNX *Westlink Report, Number 605.*

Haas Convicted

Last June, James A. Haas, 39, of Athens, Ohio, pleaded guilty in a U.S. District Court trial in Alexandria, Virginia, to federal charges of broadcasting a false officer-in-distress call and using a credit card without authorization to buy $1,000 in radio equipment. Haas, adviser to the ham radio club at the high school where he has taught physical education for 17 years, could face up to 15 years in prison. Currently out on $100,000 bail, he will be sentenced on August 30, 1991.

In April 1991, FBI agents caught Haas in his van, transmitting a false officer-in-distress call on a Prince William County police radio channel. He was parked in a Sterling, Virginia, neighborhood where he was staying with friends so that he could attend a hamfest in Baltimore. In his plea agreement, stating that he would cooperate with federal authorities, he admitted making a similar call to the Prince William County department in July 1990.

The FBI had been on Haas' trail since February in connection with similar broadcasts in Kentucky and Ohio. They suspected him of making dozens of fake distress calls, many of which resulted in massive searches by police agencies. One search that involved 15 agencies and the use of helicopters lasted 10 hours. According to police authorities, Haas could also face charges for fake calls made in Kentucky and Ohio as well as in Virginia. TNX *to Steve Boch at Universal Radio, in Reynoldsburg, Ohio, for the newspaper clipping, and Bob Blinn for the story on MCImail.*

Amateur Radio Spectrum

The Amateur Radio Service has only 2/10 of 1% of the total amount of spectrum from 0-30 GHz allocated for its exclusive use. Amateur radio is sometimes described as having generous spectrum allocations. For example, on the 220-222 MHz re-allocation, the FCC stated repeatedly that amateurs have substantial amounts of other spectrum in which to operate. A chart used by the ARRL, however, clearly shows that of the less than 5% of spectrum allocated to it, the Amateur Radio Service shares 4.5% with other services, and is subject to their interference. TNX *W5YI Report, Vol. 13, Issue #14.*

WWV Solar Report

The WWV Solar report is now updated at 2118 UTC, rather than at 1818 UTC. This is because the solar flux is currently measured at a British Columbia solar station, rather than from Ottawa. The K index will continue to be updated every three hours, as at present.

Speaking of solar activity: Those strange whistles on the low bands last June were examples of "Type II" radio sweeps generated by solar flares from sunspots in a region designated as 6659, an area at least 50 times the size of the earth. This gave DXers a major opportunity to experience the effects of major flares on radio propagation.

The onset of the flare is marked by a SID

(Sudden Ionospheric Disturbance), followed seconds later by the disappearance of HF signals from the sunlit side of the earth. About 15–20 minutes after that, a slow, decreasing whistle moves through the bands. Soon after the flare dies, the bands recover, but only to deteriorate 30–48 hours later, when the slower-moving charged particles from the sun disrupt the geomagnetic field.

Large solar flares can also produce magnetic waves that compress the earth's geomagnetic field and send power surges down electrical transmission lines and pipelines. TNX "The DX Bulletin," Issue 593, and *Westlink Report, Number 604*.

RSGB Awards Astronaut

The Radio Society of Great Britain presented UK Astronaut Helen Sharman (GB1MIR/UA) with a commemorative copy of its new video titled "Amateur Radio—The Hobby of the Space Age," in recognition of her becoming the first citizen of the United Kingdom to operate an amateur radio station from earth orbit. Last May, Sharman spent several days on the Soviet *Mir* space station and operated its amateur radio installation, talking to students in schools throughout Great Britain. Musa Manarov U2MIR was her host. TNX *Westlink Report, Number 605.*

Balloon Launch

The Dayton Amateur Radio Association (DARA) sponsored helium high altitude amateur radio experiment was successfully launched last June 29 at 9:20 a.m. The balloon attained a maximum altitude of 86,000 feet (over 16 miles) and was recovered three minutes after it landed in Beavercreek by the RDF crew headed by Paul Bohrer W9DUU.

During the 2 1/2 hour flight, the 20 meter beacon was heard throughout the world. Dara is still receiving QSL cards. The 2 meter beacon was heard, and the ATV beacon seen, out to about 450 miles from Dayton. Returns have been received from New York, Pennsylvania, Connecticut, South Carolina, Iowa, Michigan, and Kentucky, as well as Ohio.

The event was organized by Dave AH2AR, with help from many hams, including N8NEU, KB8EMD, W8LLW, N8JAF, W8ILC, W8RVH, K8GCS, and WB8ELK.

Bill Brown WB8ELK, editor of *73 Magazine,* added a 35mm camera to the balloon payload and some great photos were taken up to 60,000 feet before the camera froze.

Brown is scheduled to be the guest speaker at the first DARA meeting in October. His ATV presentation will cover high altitude unmanned balloon launches and amateur radio experiments. TNX Dave AH2AR via "RF-Carrier," Vol. 35, No. 11. *[See this month's "ATV" column for the complete story.]*

NiMH Batteries

A new battery technology may soon replace NiCds. Nickel-metal-hydride, or NiMH batteries, have 80–100% more electrical storage capacity by weight. These batteries have recently passed a testing milestone of 20,000 charge/discharge cycles at 30% depth of discharge. This could be a significant advantage for small satellites. A quantity of the new batteries is being obtained from Ovonic Battery Company of Troy, Michigan, by builders of the SEDSAT-1 amateur satellite.

The satellite will use a current-regulated power system with the voltage tentatively set at 30 volts. There will be 40 cells aranged as two batteries, giving 30 volts DC at a full charge of 100 amp/hours per battery. A prototype of the power system will be constructed at the Marshall Space Flight Center, Electronics Branch, by NASA personnel and by University of Alabama Students for the Exploration and Development of Space (SEDS), an AMSAT-NA Member Society.

In conjunction with the NiMH batteries, the 14″ x 14″ x 12″ SEDSAT-1 will use high efficiency (about 26%) AlGaAs/CIS tandem solar cells donated by Boeing Defense and Space Company, Renton, Washington.

Volunteers of the new AMSAT-NA Spacecraft Lab in Detroit, in consultation with other AMSAT-NA engineers and technicians, plan to construct the OSCAR communications package for the project. TNX "Oscar Satellite Report," Number 224.

UoSAT-F Launched in July

UoSAT-F, also known as OSCAR-22, provides store-and-forward communications for SatelLife, an international nonprofit network for health professionals. Initially, five African medical schools will use HealthNet to receive e-mail and up-to-date medical literature. When not serving HealthNet on commercial frequencies, UO-22 will QSY to amateur satellite channels, sending AX.25 data at 9600 bps.

The amateur uplink is on 2 meters, the downlink on 70cm. Stations using UO-14 will be able to receive UO-22 with the same software and hardware. Telemetry, status messages, and files are transmitted in the same pattern and format.

UO-22's role will be similar to that of UO-9, -11, and WEBERSAT. Instead of providing two-way communications, it will transmit experimental data and telemetry. It carries a CCD camera with a wide-angle lens, and will broadcast images using the PACSAT Protocol. TNX John Magliacane, MCImail "SpaceNews" for informing us of the launch, and *Westlink Report, No. 604.* Also, for more details on SatelLife, which is overseen by a distinguished board of scientists and physicians, see "QRX" in the June 1990 issue of *73*, or call Sharyn Cooper at (617) 661-6468.

11 Meter Soporific

A 27 MHz instrument appears to stimulate sleep-inducing areas of the brain, says Boris Pasche of Brigham and Women's Hospital in Boston. Co-author of a study led by Milton K. Erman of the Scripps Clinic and Research Foundation in La Jolla, California, Pasche and his colleagues are now investigating its effect on melatonin, a hormone secreted by the pineal glad in sync with the sleep-wake cycle.

Insomniacs using the device fell asleep 52 minutes faster than control subjects using inactive devices, and slept 1.5 hours longer. Although the Environmental Protection Agency reported last year that steady, weak electromagnetic fields constitute "a possible but not proven cause of cancer," Pasche says he and his colleagues do not believe this device has any adverse effects because it does not emit a steady magnetic field. TNX Miles Abernathy N5KOB for this excerpt from *Science News*, July 6, 1991.

73 BBS

The 73 BBS crashed recently (it literally fell off of the table), but it is now up and running. Since we weren't overly thrilled with the old BBS software, we politely swept the pieces under the table and installed a new BBS package called OPUS. There are separate sections for messages or files under each SIG (Special Interest Group). This should make it easier to find programs and files without having to wade through dozens of messages (as in the old software). Most of the programs and files listed in past issues of *73* are available in the "File" section of the *73 Magazine* area (it may take awhile to recover them all). Use the "Messages" section to send bulletins or leave messages. Please let us know how you like the new BBS; just leave our SYSOP Joyce a message when you log off. The BBS phone number is (603) 525-4438.

N4RVE Discovered

High tech nomad Steve Roberts N4RVE and his new computer/ham radio/gadget-laden bicycle, the Behemoth, appeared in the July issue of *Discover* magazine. In 1988–89, Steve wrote a series of articles on hamming and computing across America on his solar-powered Winnebiko. Last year, he built the Behemoth, which stands for Big Electronic Human Energized Machine. TNX *Discover* and *W5YI*.

LETTERS

From the Hamshack

David KB5LAM/4 The May '91 issue was the best yet. I'm pulling together everything I need to build 'em all. I'm on VHF packet via KK4CQ, but not too many want to QSO. Lots of "busy" messages. There are a *bunch* of hams around Pensacola. There's Sam N4SAR, who has a school program going . . . he's had his 100th licensee in the many years he's been at this.

I've finally had a chance to read the last five years of *73*, *QST*, and *CQ*. I looked for good construction articles which were interesting, but not too daunting. I marked 'em with "Post-Its." *QST* had good stuff once a quarter or so, and they asked for money a lot. *CQ* did okay with antennas, in between endless contest scores and announcements. *73* was the clear winner by a couple pads of notes. You've also gotten better. The last two years have given more encouragement and better gadgets I believe I can do.

You're a good man, Wayne Green. I've learned much from you and those you've gotten to write for you; and not just about radio. Say, if you learn of someone needing a *good* manufacturing/quality engineer, let me know. I love to build things *right*!

Tell Sam I'll believe he's making Novices when he starts sending pictures for us to publish. . . . Wayne

Rob ND1V Hello from a fellow submariner. Enjoyed your *USS Drum* (SSN) trip, wished I could have met you. I'm an ETC/SS and an Electronic Surveillance Measures (ESM) tech. I used to be on the *USS Silversides* (SSN-679). The ET school would greatly disappoint you these days. They now teach these guys to troubleshoot to the "board" level and not much deeper. A generation of black-box techs. Oh, well, it saves the taxpayers money, so they say.

That's bad news! I wonder if they can carry enough spare boards to fix anything that goes wrong? The next step is to have the boards self-checking so we can save taxpayers the whole ET school cost. With two of each board in every unit, a future ET would only have to replace the bum boards as they burn out. The equipment would keep right on running. . . Wayne

Thomas Wyckoff, Kenilworth NJ I picked up a copy of *73 Today*, and the only thing I didn't like about it was that the back page was too close to the front page.

I passed the tests for the no-code Tech last week, and have been listening to the bitching on 2 meters while I wait for my license to arrive. I wonder how these old geezers would react if they were told that they had to pass a test on IBM 360 assembler before they would be allowed to connect a PC to their rigs and get into packet radio.

One of the things the FCC was created for is to balance the allocation of the frequency spectrum with the needs of the users. Since we are only one-quarter of one percent of the population, I can see us losing a lot of frequencies in the future unless we greatly multiply in numbers, and do it quickly. Us no-code Techs may well be the salvation of amateur radio, not its downfall. Sooner or later some politician will stumble on the fact that 99.95% of the population is limited to CB or cellular phones, and make an issue out of it. When that happens, God help amateur radio. Cellular phones are nice, but every time I look at mine, I am reminded of a TV game show from about 30 years ago, a show called "Dollar a Second."

Doug Pine NH6ZA, Makawao HI I was re-licensed last month after almost 15 years of inactivity. At age 13 I was an active General class ham (WA6CKK) and proud of it. I even had a subscription to your magazine and was a member of the ARRL. Before too long, though, high school, surfing, and girls turned my head. I wanted to remain an active ham, but no one I knew among my ham friends wanted to talk about anything but electronics, repeaters, and transistors. I always thought there was more to the hobby than that, and for a while I knew a few people on 40 meters who agreed with me. We talked about surfing, music, politics, religion, drugs, women, and anything else we felt like. We weren't using foul language or improper procedures. We were within the bands, and we identified legally, and anyone was welcome. We were exercising our minds and our hobby at the same time. It was FUN! We called ourselves the "Free Thinkers' Net," and had a grand old time of it. After a few months, we began getting harassed and even jammed by "proper" hams who felt it was their duty to "keep us in line," as one OM put it. I called it quits at 17, sold my station, bought a surfboard, and moved to Hawaii.

Now I'm 30, married with a kid on the way, settling down, all that scary stuff. The radio bug bit again about a year ago. This spring I got out the study guide and passed my General class exam. I haven't gotten on the air yet for lack of a rig, but I will soon. I picked up the June issue of *73* and read it. Lots of new things; let's see. . .this packet stuff looks interesting, satellites are happening, the latest rigs are amazing. I read your editorial. Nice satire about the QSO machine, but the point it made caught my attention the most. The same stuff I tried to do 15 years ago—get beyond the standard QSO: name, QTH, rig, pse QSL, 73 and good-bye. Communicating. Learning about human beings on the other side of the world firsthand. I'm hoping to be able to do just that when I get back on the air. I'm not at all surprised to read that most hams still don't communicate beyond the most basic level.

I wasn't surprised to read about all the furor over the no-code Tech. Old traditions die hard, don't they? Knowing how to send 30 wpm doesn't make me a good operator; my desire to be one leads me in that direction. I don't know jack-diddly about theory. Does that make me an unwanted member of this fraternity? I just love the magic of radio, period.

I took my test with a room full of people going for the no-code. They were sincere and excited about their entry into this hobby, and almost without exception planned to continue onwards and upwards. More power to 'em, I say.

Doug, Max Planck (the physicist who formulated the quantum theory) said it this way: "A new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die and a new generation grows up that is familiar with it." Or, as my grandmother used to say, "A man convinced against his will is of the same opinion still." So Doug, let's keep watching the Silent Keys list as the CW fanatics are gradually all listed and replaced by newcomers. . . . Wayne

Rudy Ault N2JZK, Troy NY My latest issue of *73* arrived today. As usual, I was reading "Never Say Die" before the plastic wrapper hit the floor. The things I found irked me into writing this letter at the odd hour of two a.m.

I live in the Albany-Troy-Schenectady area of New York. There are some things going on over here that you may find out of the ordinary for amateur radio these days. In your last issue you mentioned passing through Troy and not being able to find anyone on a repeater. You must not have tried the 147.27/.87 machine on the Ch. 13 tower at Bald Mt. There is a group of people there who don't fit into the amateur mold. We joke around, we discuss everything from the Civil War to astronomy, we are HAMS. You would fit in here, Wayne. Why not try to call us one night? This machine has a tremendous range.

Bill Eddy NY2U is the president of the Troy Amateur Radio Association. He was important in founding the Capitol District Amateur Radio Council, CDARC, which co-ordinates the efforts of the member clubs in this area. They even sponsor a twice-weekly bulletin broadcast on all member repeaters. Steve WA3RKB keeps us informed of events, news, and VE exams, all via 2 meter repeaters.

The Rennsselaer County RACES club is making great strides in interlinking its three repeaters to give full 2m coverage to the county. Lance WS2B is doing the hookups (with a small break to graduate from high school). Lance, an Eagle Scout and the repeater manager for the county RACES, is 17-years-old.

Since I got my first call in 1988 (KB2FVR), there has been an average of one VE session per month in this area. I upgraded to Technician and drug my poor wife into the hobby as she kicked and screamed. Her call is KB2LGA. She is also a Technician. My brother-in-law is now waiting for his new Technician ticket. He cannot do code, Wayne, but he has written several computer programs that will. My brother Ricky passed his Novice written, and is planning on getting his Technician soon. He will be quite an asset to the Frederick County, Maryland, area.

Some of us *are* trying, Wayne. Some of us do dream, and hope, and work to better the hobby. When you get in town again, give a call to some of our clubs . . we are in the Yellow Pages!!!

William A. Ward N4BLR, Atlanta GA I am a black ham operator and proud of it. For years I have read your "Never Say Die" editorials devoutly, and have always enjoyed them. After reading what K9RGV had to say about the contributions of black hams, I agree with him, but I am personally fed up to here with the notion of having to have a "set aside program" for black hams. What will be next? A set-aside page for gays, Native Americans, etc.?

If you want people to know about you, the answer is PR and plenty of it. The percentage of blacks in ham radio is less than 1%. Here in Atlanta we have between 75 to 100 black hams. We have what is called the "corner" where quite a few black hams hang around. Some never leave these frequencies because they might have to talk to someone other than a black. It has always seemed to me that there's an underlying fear out there to talk to anyone unless they're black.

Having been born in the South, I know that some people's attitudes haven't changed much, even on the ham bands. I don't expect these bigots to change. From the time I received my ticket, I've operated all of the bands that I was licensed for. I've never been afraid to talk to anyone who would talk to me. I've met and had quite a few friends on 75 meters, especially around the Georgia SSB net frequency of 3.975, and I couldn't have met a nicer bunch of fellows.

Wayne, I've talked with some of the older black hams, and they have told of the hell they caught in the '50s, '60s, and '70s, and I can understand their frustrations and attitudes. However, we are living in the '90s, so let's act like we're living in the '90s. I am not going to shut myself off from the rest of the ham community.

What have I done in ham radio? I was instrumental in forming the Metro Atlanta Amateur Radio Society. I started a 40 Meters Traders Net three years ago, which has grown steadily. Incidentally, a few people said I couldn't get it to work because I'm black; what do they know? I reactivated an old net, the Fourth District Amateur Radio Society, that had quit operating. This net is geared towards sharing your technical expertise with others. I've appeared on a talk show to explain what ham radio is, and how one can get into it. I've built quite a few projects out of *73* over the past years, and I've enjoyed reading *73*. Most of my knowledge of electronics is self-taught by reading and experimenting.

Finally, I want to agree with you on boring QSOs. I'm really tired of conversations that are Boring, Boring, Boring. There must be a million things a person can talk about, but most never do. Does anyone ever watch any National Geographic Specials or C-Span or read any books? Are there any builders out there working on a new design? Every now and then I run across someone doing just that, and it's a pleasure to talk to him.

C.R. Phillips N3HTZ, Langhorne PA The president of a local repeater came on and chastised two new hams and myself for having a "CB rag-chew" on his club's repeater. What I want to know is what constitutes a CB rag-chew? I will not, and many of my friends agree, put my personality aside to talk on ham radio. I do not curse or talk about taboo things on ham radio, but I try to make interesting conversation. What an example the president of this local repeater club is setting towards new hams, and hams who may be traveling in the area. Keep up the good work, Wayne.

73 Review

by David Cassidy N1GPH

The Outbacker All-Band HF Mobile Antenna

Results of a 12-month road test.

Outbacker Antenna Sales
330 Cedar Glen Circle
Chattanooga TN 37412
Price Class: 6 ft., $259; 4 ft., $219; 6 ft., 2-piece, $289.
Tel. (615) 899-3390.

Photo A. The Outbacker.

A little over a year ago, a new mobile antenna became available to the ham radio market. Called the Outbacker in honor of its Australian origins, this rugged yet attractive antenna soon began to show up on the bands and to receive some nice reviews in amateur radio publications.

For the last 12 months, I have been testing the standard one-piece, 6-foot, 8-band Outbacker. It has gone through a New England winter, has been installed on three different automobiles, and has been used as a base antenna at two different locations.

A Little History

The Outbacker antenna, as its name suggests, is a product of the Australian Outback. Terlin Aerials of Australia has produced this antenna for 15 years, serving customers who need a no-nonsense mobile antenna that can survive the extreme conditions of the harsh Australian Outback. The Outback is a vast area of the Australian continent where ranches are measured in hundreds of miles. There is no telephone service to most of this area, so those who live and work there rely on HF and VHF radio for just about all of their communications. When the nearest medical facility is hours away by air, even a compound fracture can turn into a life-threatening emergency. To people of the Outback, the performance of their radio gear is literally a life-and-death matter.

The man who brought the Outbacker to the U.S. market is Don Arnold WD4FSY. Don is a professional photographer who travels the world. When his profession brought him to the Outback of northern Australia, he noticed that every Jeep, Land Rover and truck had the same thing—an epoxy resin coated multiband antenna. Being a ham, he checked into this unusual looking aerial. What he discovered is that Terlin Aerials manufactures these HF antennas in a variety of multi-band configurations—for business, marine. Don received a ham band version of the Outbacker, and was so impressed that he arranged to have a few more sent as prototypes. Thus was born Outbacker Antenna Sales of Chattanooga, Tennessee.

The first time I met Don face-to-face was at the Southwestern Convention in San Diego. Since then I've seen him at every major hamfest, usually with the same set-up. He gets a booth by the door, runs some coax to the outside, and sets up one of his Outbackers (usually hidden in a potted plant or some other form of shrubbery). Don is also fond of demonstrating the strength and durability of his product by bending the antenna almost fully back on itself, inviting passers-by to slam the antenna against the floor, or by pounding the living daylights out of the antenna with a hammer. I've seen this demonstration dozens of times now, and I've yet to see an Outbacker damaged by this rough treatment.

The Antenna

The Outbacker is a hollow fiberglass pole covered with a black epoxy resin and a final protective coating (if you're willing to wait several weeks, you can order an Outbacker direct from Outbacker Antenna Sales in almost any color you want). There's a 6-foot version, a 4-foot version, and a 2-piece 6-footer.

The main antenna is a helical copper coil. Each antenna is handmade by Terlin Aeriels of Australia. After the antenna is manufactured, each is hand-tuned for accuracy and field tested for each band of operation.

The unique way the Outbacker provides all-band performance is something they call the "wander lead." The wander lead is coiled around the outside of the antenna, and one end is inserted via a banana plug into a jack near the base of the antenna. The antenna has a series of silver-coated brass jacks recessed into the fiberglass, each jack corresponding to a different band of operation. To change bands, you simply wind the wander lead around the antenna and insert the plug into the appropriate jack.

There is also a short whip at the top, which allows for fine tuning the SWR. The whip has a mark scored on the side. Setting the whip at this level gives you a good SWR from 40–10 meters. If you want to operate 75 meters or the high end of 10 meters, it's a good idea to put an SWR meter in line and reset the whip.

You can purchase a heavy duty spring mount from your Outbacker dealer. This is one of the sturdiest mobile mounts I have ever seen, and if you have the type of vehicle that can accommodate this, it would probably survive long after the vehicle crumbled to dust. For those of us who don't want to permanently alter our rubber-bumpered cars, Outbacker suggests the 4-foot Outbacker Jr. model with a Diamond K400-3/8, 24 lip mount. This grips your trunk or hatchback with only a couple of puckers on the internal side (which helps ground the mount to the car body) and holds up fine to highway speeds. Mounting the antenna at trunk or hatchback level also gets the majority of the radiating surface above the car body. This arrangement is only for the 4-foot Outbacker, and you need to put a heavy duty spring between the mount and the antenna.

The One-Year Road Test

There is a right way to install a mobile antenna and a wrong way. Not wanting to wait to test out the Outbacker, I immediately ran down to my local Radio Shack and purchased one of those bumper mounts with the little clip and chain arrangements. These used to work just dandy on older cars with metal bumpers, but I quickly found out that my old rust-bucket was equipped with those darn rubber bumpers. Undaunted, I found a place to clip the hold-down chains, braced the whole thing with a bungee chord so the 6-foot Outbacker wouldn't sway in the breeze, ran the coax to the front of the car, hooked up my HF rig and away I drove. (In case any of you are wondering, this is the wrong way to install a mobile antenna.)

My first contact was on 20 meters with a ham in Manchester, England. He was very cooperative in answering questions about my signal and reported a strong 5 x 7. Not bad for 100 watts, a stock hand mike and an antenna that, despite the bungee cord arrangement, was tilting in the breeze at about a 30 degree angle! After clearing with the chap in Great Britain, a ham in Florida called to report that he was receiving me at about the same 5 x 7.

For the next few weeks I checked into WB2JKJ's Classroom Net on 40 meters (7.238 MHz at 7 a.m. This is a great rag-chew net for

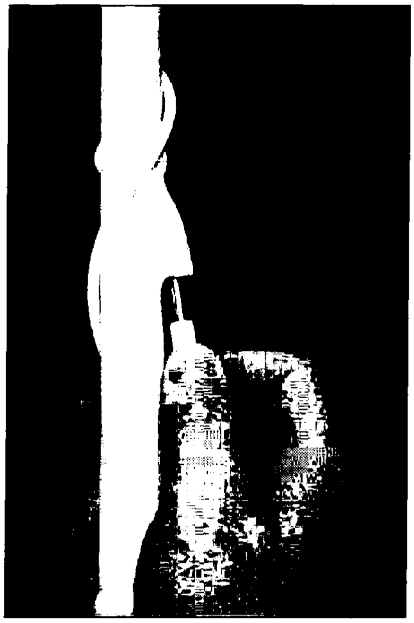

Photo B. To change bands just wrap the "wander lead" around the antenna and insert the jack into the appropriate plug.

morning commuters. It is operated by Joe Fairclough—one of the nicest guys you'll ever meet in ham radio—out of The Radio Club of Junior High School 22 in New York City.). The net was very helpful in establishing the omnidirectional performance of the antenna. Consistent reports from upstate New York, Virginia and Canada proved the Outbacker was putting out a nice signal to all points on the compass.

Since I knew my car was destined for the junk pile, I didn't bother with a more permanent mounting arrangement. For using the 6-foot Outbacker, I would suggest either side-mounting the antenna (which requires drilling into the car body) or some kind of trailer hitch arrangement. Both of these options can be done using the heavy-duty spring mount mentioned earlier.

The Outbacker as a Base Antenna

Not too long ago I was living in a one-bedroom apartment. I tried all kinds of schemes to get an HF signal out with indoor or invisible outdoor antennas. Though I now have plenty of space for outside wires, I was anxious to test the Outbacker as an apartment/condo antenna.

A quick trip to the hardware store or Radio Shack should provide you with all the ideas and materials for fabricating a window mount for the antenna (I used the bumper mount mentioned earlier, and a few clamps and L-brackets from the hardware store). Open the window, mount the antenna, run the coax, and you're on the air. From my ground floor location, I was not setting the bands on fire, but I made plenty of contacts—especially on 10 and 40 meters. Changing bands was a matter of opening the window and reaching out to change the wander lead. I figured this was a small price to pay for 80–10 meter capabilities. When I was done operating for the evening, I simply brought the antenna in.

The secret of operating with this type of arrangement is the ground connection. The antenna mount should be wired to the best possible ground available. Some of my QSOs reported a 3–5 dB loss of signal when I disconnected my cold water pipe ground lead. If a ground is not available (or in addition to a ground), a 1/4-wave counterpoise wire can be attached for each band of operation (using ribbon cable for this will keep things neat). Either throw the counterpoise wires out the window or run them along the wall of your shack.

An alternative for those who have first floor apartments is to park your car near your shack, leave the antenna mounted on your vehicle, and run the coax into your shack window.

Don't expect to break into any 20 meter pileups with this arrangement, but you'll still have plenty of signal for normal rag-chewing. I think the Outbacker is a great choice for the apartment/condo ham.

Further Road Work

When I traded in the old clunker for a new compact car, I was leery of mounting any antennas on

Photo C. The adjustable tip allows for fine-tuning SWR.

that nice shiny paint. When the new car went back to the dealership for service, I was provided a loaner vehicle. The desire to check in with some friends on 80 meters during a late-night/early-morning solo drive across New England provided the perfect opportunity to test the Outbacker in another configuration.

I mounted a 4-foot Outbacker Jr. to the car with a Diamond trunk mount (make sure you use a heavy duty spring and NEVER attempt this with the 6-foot Outbacker), ran the coax to the front seat, and I was on the air. Total install time: five minutes.

The performance of the 4-foot Outbacker Jr. is surprisingly close to the performance of the full-size version. I didn't have any trouble making local contacts on 40 meters, and I was able to key up the Virgin Islands 10 meter repeater with only 20 watts. That evening, I QSOed with my friends on 80 meters for over two hours. I usually received them at the same level I do from my home shack—10 dB over S-9. When I first joined the roundtable, they were shocked to discover that I was operating mobile. Solid S-9+ signals were reported throughout my journey.

For those who travel and use rental cars a lot, an Outbacker Jr., a Diamond trunk mount and a small HF rig would be a perfect travel setup. The 6-foot Outbacker is offered in a two-piece model, but the trunk mount won't handle this antenna. If Outbacker would come out with a four foot, two-piece version, the entire set-up could fit in a carry-on bag.

Final Thoughts

To put it bluntly, I am very impressed with the Outbacker. It is easily the most attractive multiband HF antenna available. The black epoxy can be buffed to like-new condition with auto wax, so even after a New England winter (where salt and sand coat the roads for four months), the antenna looks like it just came out of the box. If you're willing to wait, you can even order an antenna that matches your car. (Outbacker offers other special models, including HF marine. In fact, you can special order just about any combination of special frequencies.)

The Outbacker is hand-made, and the quality is evident. Plugs and jacks are silver coated brass. The wander lead is heavy enough to stand up to weather, but light enough to easily wrap around the antenna. I can't imagine how anyone could damage this antenna, even under extreme conditions. The final coating applied over the epoxy resin will sometimes peel a little around the recessed jacks, but this is barely noticeable, and in no way affects the strength or performance of the antenna.

I found the on-the-air performance of the Outbacker equal to any other mobile antenna I have used, and the wander-lead system of band switching very convenient—much easier than carrying around a trunk full of loading coils.

When you take great mobile multi-band performance and add the easy portable and apartment/condo applications, I think the Outbacker is a great choice for a variety of HF antenna uses. 73

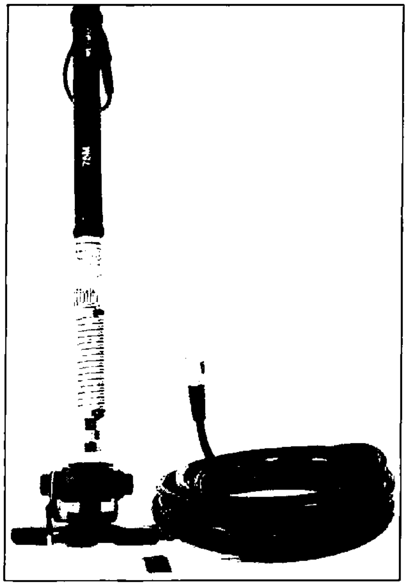

Photo D. The Diamond K-400 mount. Outbacker recommends this sturdy trunk/hatchback mount for the 4-foot Outbacker Jr.

The Square Pancake Antenna

The indoor marvel.

by Ken M. Doolittle W2SMR

Apartment dwellers, ATTENTION!! Here is a limited-space, simple, and inexpensive inside antenna that works. I've made hundreds of complete QSOs with this little 20-inch square that hangs from the ceiling over my rig. I can reach up and tune it in a few seconds. Frequency coverage is 80, 40, 30, and 20 meters.

For comparison, I often switch to my 40 meter center-fed Zepp. With 1–50 watts into the antenna, signal strength reports vary from 0–5 S-units below the Zepp. Not bad for an inside antenna only 10 feet above the ground.

There's nothing magical about this antenna. The basic design has existed in various forms for many years, but it has seen little use for transmitting because of high losses. However, in spite of losses, you will be amazed at the results you can get. Twenty meters, for example, has yielded many DX stations. On 3537 kHz, I worked YU7WW in Belgrade.

Originally, I built this small antenna for local schedules on 80 meter CW, using less than 1 watt of power. Then, one night in November 1988, I was surprised to hear a Connecticut station calling me. Subsequently, I found that many distant stations could be worked on 1 watt. This led me to redesign the antenna, using thicker wire, and adjusting it to cover the other bands.

One time I was using this antenna in a three-way QSO on 30 meters. One of the stations became really hostile when I described my antenna, and did everything but call me a liar. He threatened to come to my home from Massachusetts and see my antenna himself. I told him to come along, but he finally got so upset he quit talking. It was one of the strangest things!

Construction

See Figure 1 for details. The plywood bottom piece is glued and nailed to the bottom of the vertical, 30-inch-long cross-piece. The vertical piece is 1 inch longer on the bottom to space it away from the plywood bottom piece. Attach the 29-inch cross boom to the vertical support piece. Starting from the edge of each support piece, cut seven ¼-inch deep grooves spaced about ¾-inch apart (see Figure 2). Angle the grooves so that the bottom of each groove is closer to the center point of the antenna. That way when the wire is wound around the support pieces, the grooves will keep the loop tight.

Drill a ⅛-inch hole ¼ of an inch above and below the seven grooves on the bottom portion of the loop. These holes are used to anchor the beginning and end of the wire loop. Cut a 37.5-foot length of #16 copper wire and loop one end through the bottom hole and run it down to the bottom attachment plate. Now loop the wire around through the grooves until you have 7 full turns in place. Run the end of the loop wire through the top support hole on the bottom support leg and tie it in place. A small wire loop can be placed through a hole in the very top piece of the antenna so that you can hang the antenna from the ceiling.

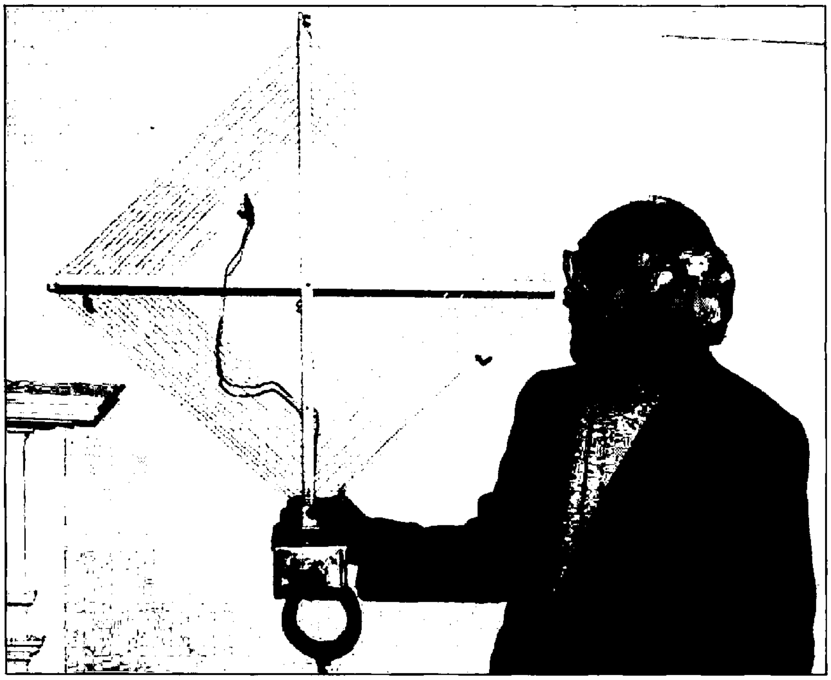

Photo A. The Square Pancake Antenna is a convenient indoor size.

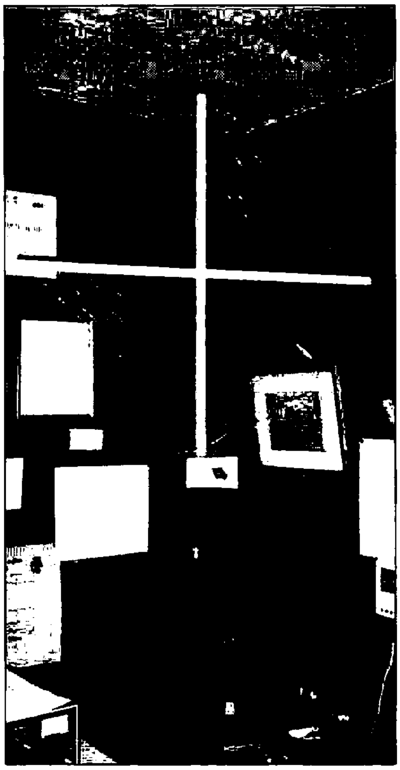

Photo B. The Pancake, over the operating desk. The tuning clip is in the 30m position.

The Tuning Capacitor

See Figure 2 for the tuning capacitor mounting details. Cut out a plywood support plate large enough to attach your tuning capacitor and the coax connector and mount it to the bottom of the vertical support piece. Mount the tuning capacitor to the bottom of the support plate and attach an SO-239 coax connector next to the back of the capacitor.

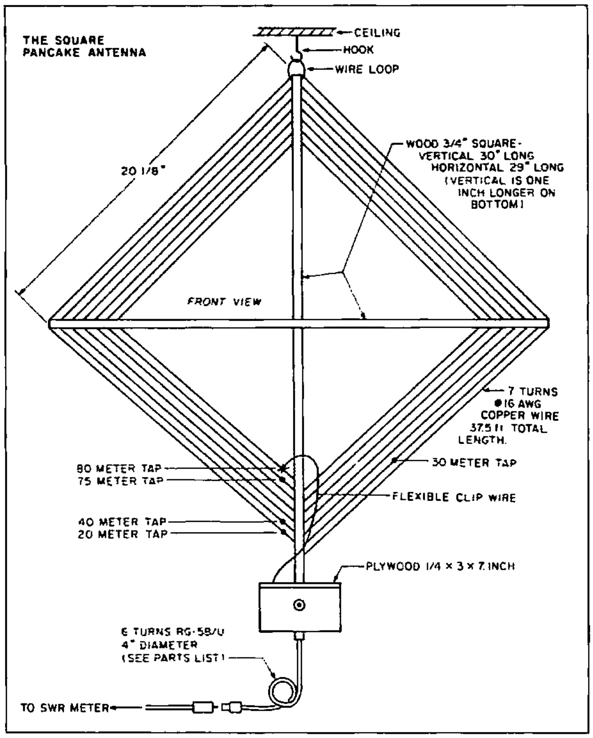

Figure 1. Front view of the Square Pancake. Note: If there is any problem when tuning a specific band, try adding the optional jumper (dotted line on the figure) to the end of the loop wire.

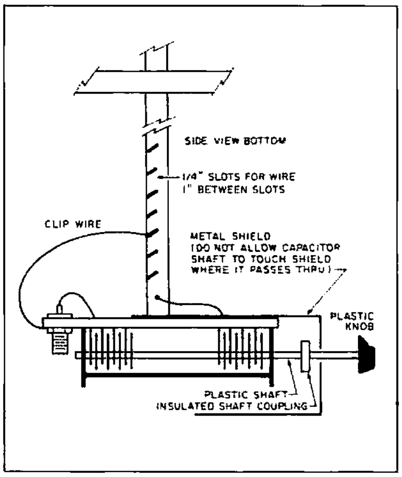

Figure 2. Side and bottom view showing the tuning capacitor arrangement.

Wire the center pin of the connector to one end of the capacitor and hook up a 2-foot clip wire (alligator clip attached on the end) to the shield of the connector. This clip wire is used to tap the loop for the various bands of interest.

Make up a shield around the front of the tuning capacitor. (DO NOT allow the capacitor shaft to touch the shield. I coupled a plastic shaft and knob to the capacitor where it passes through the shield.) You can make the shield out of a piece of aluminum or tin from a coffee can. Cut a ¾-inch slot in the shield so that it can straddle the vertical stick. I drilled four small holes in the shield and used four small bolts to fasten it to the plywood piece. Very small wood screws would also work. Attach the bottom end of the wire loop to the front end of the capacitor.

If you don't want to hang the antenna from the ceiling, you could build a small, table-top cabinet for it; but you'd have to be careful to keep children and pets away from it when using it to transmit.

The 150 pF split stator capacitor is placed in series by allowing the rotor to float. This reduces the capacity to 75 pF and doubles the voltage. If you do not plan to run over 10 to 20 watts, you could use a wide-spaced single capacitor of 75 to 100 pF. If you can't find the capacitor at a hamfest, you can use a Millen #284130 dual section variable (12–115 pF); for lower power operation (under 50 watts) try a single section Millen #23100MK (7–100 pF). Both are available from Radiokit, P.O. Box 973, Pelham NH 03076. Phone: (603) 635-2235.

Reducing Loss

You can do several things to reduce the losses of this antenna.

Use larger wire. This will, however, change the tuning.

Look for a capacitor in which the plates are welded to the mounting bars and shaft. (I am not presently using a capacitor of this type, however.)

Place a rotary switch in the middle and wire it to the tap points. The switch contacts will still cause some losses.

My feeling regarding losses is to do the best with what you have, and give it a try. All antennas have some losses.

Tuning Up

The taps shown agree with my setup. Yours will probably be different. You'll have to find them during the tune-up process.

Do all your tune-up at as low an RF power as possible.

Attach the alligator clip to the 80 meter position (at the far end of the wire). The coax from your antenna should go to your SWR meter, and from the meter to your receiver or transmitter. Set the frequency desired. In this case it would be 3500 kHz. Another tap will be required for 3750 and 4000 kHz.

Slowly adjust the antenna capacitor until the noise or a signal increases in volume. If this doesn't occur at any capacitor setting, check your wiring. If this is OK, move the tap until it does take place.

Apply as small an amount of power as possible, and adjust the capacitor until the SWR is as close to 1:1 as you can get. The SWR should not be more than 1:2. If necessary, move the tap wire and tune for lowest SWR.

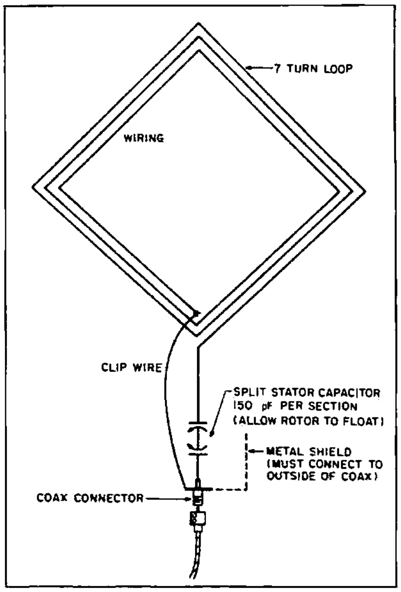

Figure 3. Wiring the Pancake.

Once you find the tap point, you should only have to use the tuning capacitor to lower the SWR from about 3500 kHz to 3750 kHz. A new tap point will be necessary for the rest of the band.

Follow the same procedure for the rest of the bands.

If you make a frequency change of over 20 kHz, you'll have to use the capacitor to tune for lowest SWR; however, you shouldn't have to move the tap until about 3750 kHz, or when you can't achieve an SWR below 1:2 by use of the capacitor only.

Once the tap points have been found, mark them for future use.

Remarks

This design is not for outside use. A very high *Q* antenna such as this is not practical outside unless it's well-protected from the elements and you use some type of motor tuning.

There are HIGH VOLTAGES present on this antenna when transmitting. Keep this fact in mind at all times.

This antenna will arouse controversy among the VIPs of antennadom. Regardless of this, give it a try and decide for yourself. You can build the whole thing in about three hours with very little expense.

You may contact Ken M. Doolittle W2SMR, Box 553, Newark Valley NY 13811.

The Square Pancake Antenna

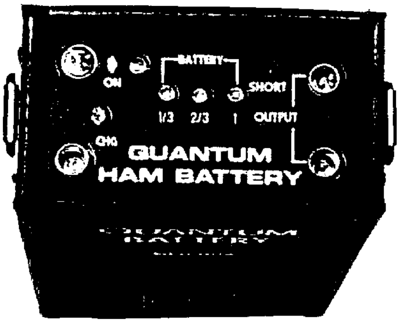
Price Class: Ham Battery $125, HT Adapters $30.



Quantum Ham Battery

Full power for your HT.

Any professional or serious amateur photographer is probably familiar with Quantum Instruments. For over eight years, Quantum has been the leading supplier of power packs to the photographic industry. Their products have been proven to be reliable, whether it's a wedding photographer snapping candids of a radiant bride, or a news photographer slogging through the jungles of South America. Photographers the world over rely on Quantum battery packs to supply full power in the field. Quantum Instuments has now brought their experience to the amateur radio market with the introduction of the Ham Battery.

The Quantum Ham Battery is a hefty (36 oz.) power pack that will provide full, 12 volt power to your HT. There are several things that make the Ham Battery different from the standard NiCd pack. First and most importantly, the Ham Battery is not a NiCd. The attractive black case contains a sealed lead acid battery rated at 12V and 2.1 Ah. Since the battery is designed for high current drain, it can handle up to 3 amps of current draw. Also, since the battery is not a NiCd, there is no problem with "battery memory." You can recharge the battery at any time, without the risk of shortening the battery life. Since the charging circuit is fully regulated, there is no danger of overcharging.

The other big difference in everyday use is that the Ham Battery does not attach directly to the bottom of your HT. The battery is hung on your belt with a built-in belt clip, or you can use an optional shoulder strap.. An adapter is plugged into the top of the Ham Battery; the other end replaces the battery pack on your HT. You can then use your HT as a speaker/mike, or you can leave your HT on your belt and use a regular speaker/mike. The adapter is so lightweight that with most mini-HTs, it is most convenient to use the whole radio, instead of having the additional tangle of a speaker/mike.

To test the effectiveness of the Ham Battery, I subjected it to several real-world situations (if you can call the Dayton Hamvention "real world"). The Ham Battery has three green LEDs which show the approximate state of charge. They are marked "1," "2/3" and "1/3" (with "1" meaning full charge, etc). Eight hours of constant monitoring and occasional transmitting never did more than put out the first light. Hooking my HT up to a wattmeter showed that I was getting a full 5 watts out at this level (my HT's maximum output at 12V). Every evening upon returning to the hotel, I plugged the wall charger in and woke up to a fully charged battery, without the worry of NiCd battery memory.

After doing this at three separate hamfests, I figured it was time to give the Ham Battery a tougher test. The opportunity came when my car went into the shop for some repairs and I was given a loaner. I threw the Ham Battery in a dash cubbyhole, stuck a 5/8 wave mag mount on the roof and set my sights at full battery drain. This set-up took me on a six-hour trip over the weekend, and back and forth to work every day (about 1 hour/day total) for a week—without a recharge. When I returned the loaner car a week later (and gratefully went back to a full 45 watts of output on my in-dash 2 meter gear), the "2/3" light was just starting to flicker. Granted, I probably didn't transmit as much as most people. I doubt that someone who is more of a rag-chewer than I am could repeat these results, but since you're probably never more than a full day away from an AC outlet, you could probably go for years without ever seeing that last LED go out.

The Ham Battery has two output jacks, so you can power two units at once (just don't exceed 3 amps draw). You can order a coiled power cord without an HT adapter, so you could power anything that takes 12V DC. This seems like the perfect power source for taking a QRP rig on that next wilderness camping trip. In fact, there's probably a hundred different ways you could utilize a highly portable 12V power source.

Come to think of it, I'll be spending a few days in a canoe in the backwoods of Maine this month. Hmmm. . . I wonder if DXCC has a special certification for QRP canoe maritime mobile?

Indoor 10 Meter Beam

A 2-element coaxial antenna.

by Jacquelyn J. McGlothlin N9CAP

In May 1981, I wrote "The 'No Antennas' Antenna," which appeared under my former name and call, Jacquelyn Schoewe WA9BBX. It was intended to shed some light on the problems many of us face when the landlord says, "No indoor antennas!" What do you do, give up your hobby? No way! You resort to an indoor, "invisible" antenna. What is not seen will not be noticed. From the mail I received, it appears that many of you tried the indoor coaxial dipole with great success. For those of you who wish to go one step further, here's an indoor, invisible coaxial beam that will improve your signal both ways. It requires only another length of coax to turn the original dipole into a beam.

The coaxial beam antenna has the same features as the coaxial dipole. It greatly attenuates harmonics, thus lessening any TVI problems. This antenna is also very broadbanded, covering the entire 10 meter band with a VSWR under 2:1 at band edges. The broad-band characteristics are due to the feedline being matched to the antenna and electrically incorporating its own balun. The coaxial beam antenna has a definite gain over a coaxial dipole, with 5-6 dBd being typical. It is also a very "quiet" antenna; the vinyl jacket reduces static charge build-up that can cause a popping noise in the receiver when discharged.

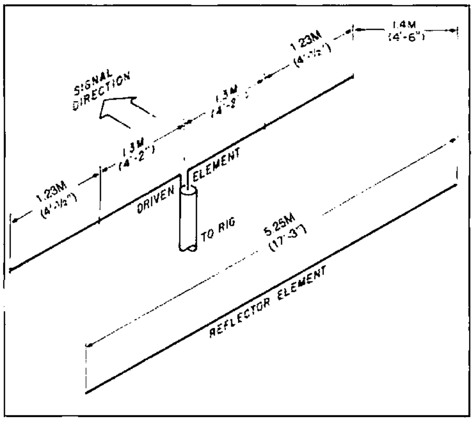


Figure 1. Element lengths for the 10 meter beam.

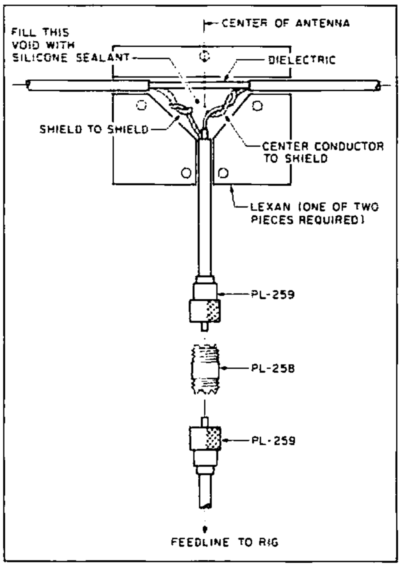

Figure 2. Feedpoint connection.

First, the Dipole

I'll begin with step-by-step construction of the 10 meter dipole, then modify it into a 2-element, 10 meter beam antenna. For antenna dimensions, see Figure 1.

Construction of the antenna is simple. RG-58A/U coax is best because it's light and flexible, but you can also use RG-8/U or RG-8X. Maximum legal power can be used with any choice of coax, providing the VSWR is under 1.5:1.

Begin construction by removing 1" (2.5cm) of vinyl jacket (1/2" on each side of center) at the center of the antenna. Cut the shield in the center all the way around the coax. Take care not to cut the dielectric or the center conductor. Next, form two leads with the shield, as shown in Figure 2. This is the feedpoint of the antenna.

From this center feedpoint, measure out each side of center 4'2" (1.3 meters) and cut the coax at that point. Remove approximately 1" (2.5cm) of vinyl jacket from each of the ends, and fold back the shield so that the dielectric is exposed. Cut and remove about an inch of this dielectric, being careful not to cut the center conductor. Then, twist the shield and center conductor together and solder. Do this at both ends. It forms the 52 ohm matching section and balun.

Next, cut two lengths of coax, each 4' 1/2" (1.23 meters) long. Then remove an inch of vinyl jacket from all four ends, fold back the shield, remove the dielectric, and twist the shield and center conductor together as before. This forms the end sections of the antenna. Attach one of these end sections to one end of the matching section by twisting together the prepared ends and soldering. In the same fashion, solder the remaining end section to the other end of the matching section. If you plan to install this antenna in an attic or outdoors, waterproof these joints as best you can. This will prevent any moisture from seeping in and deteriorating the coax. An easy method is to use heat-shrink tubing over the joint, heating it until it shrinks snugly, then wrapping it tightly with black vinyl electrical tape. Waterproofing the ends will come later, as they may need trimming for tuning purposes.

Attaching the Feedline

Refer to Figure 2. A short length of coax approximately 12" (30cm) long will do, providing it is of the same type used for construction of the antenna. Remove about 1" (2.5cm) of vinyl jacket from one end, fold back the shield, and remove the dielectric, being careful once again not to cut the center conductor. Form two leads with the shield and center conductor. At the feedpoint of the antenna, connect this feedline by soldering the feedline center conductor to one of the feedpoint leads. Then solder the feedline shield to the remaining lead. Waterproof this area if desired, being sure that the feedpoint leads do not touch each other and short out. One method is to cut two pieces of 1/4" (6.5mm) thick Lexan or similar material into a 3" x 4" (7.5cm x 10cm) shape.

Using a router or hand chisel, remove enough of the material inside each half so that it will make for a snug fit over the feedpoint. Fill this area with silicone sealant such as RTV prior to sandwiching the halves together. Drill holes through both pieces at a few locations to allow for several screws, nuts, and lockwashers to hold the unit tightly together. Drill a hole at roughly the center top portion of this insulator block so that a small nylon rope may be passed through it for supporting the center of the antenna later. At the opposite end of the feedline, attach a PL-259 connector and a PL-258, also called a barrel connector. Then prepare a random length of

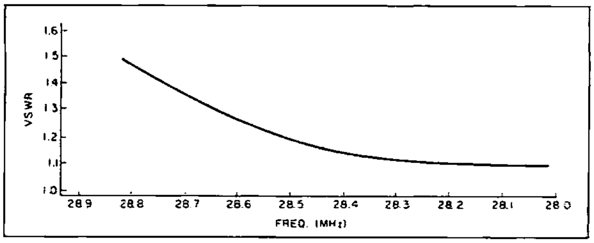

Figure 3. VSWR curve.

coax long enough to reach from the antenna to your rig and attach PL-259s to both ends. This will allow you to easily switch from one antenna to another, if desired, merely by unscrewing the feedline and attaching it to another antenna of your choice.

Erecting the Antenna

In choosing a location, be sure to allow enough room for an additional element running parallel to and approximately 4'6" (1.4 meters) away from the antenna. It should also be oriented in your favorite direction, as indicated by the arrow in Figure 1. An attic or crawl space will provide ample room in most cases. Try to erect as much of it as possible in a straight line, keeping it as far away from large metal objects as feasible. The ends may hang down as long as they don't touch any nearby metal objects. Monofilament fishing line tied in a series of half-hitches along the vinyl jacket ends of antenna will do nicely for anchoring it. The line will bite into the vinyl as it is pulled taunt.

If you don't have an attic or access to one, the antenna may be stapled to a ceiling with plastic cable ties or any other non-conducting material as support. Wrap the cable ties around the antenna at intervals and staple the free ends of the ties to the ceiling. Do not staple directly through the antenna itself. Again, the ends may hang down if need be, providing they don't touch any nearby metal objects.

Tuning the Antenna

After erecting the antenna, check VSWR and trim the ends if needed, keeping track of the total amount trimmed. I used a design frequency of 28.5 MHz for tuning purposes. Be sure to twist the ends of the antenna as before (shield to center conductor), then recheck VSWR. The antenna will interact with any hidden wiring in the walls or ceiling, so a considerable amount may have to be trimmed from each end. Try to achieve a preliminary VSWR of 1.5:1 or 1.6:1 at the design frequency of your choice. This completes construction of the coaxial dipole at this point, so now we'll call it the driven element, and continue its transformation into a 2-element beam antenna.

The 2-element Transformation

The reflector element which we'll add requires only another length of coax, the same type used for construction of the driven element. To determine the length of the reflector, note the total amount, if any, trimmed from the driven element (you did keep track, didn't you?). Subtract this from the total starting length of 17'3" (5.25 meters) to derive the actual length. This is the length required for the reflector element.

Cut a new length of coax to that dimension and prepare each end as you did with the driven element, then twist together as before (shield to center conductor). Erect this element in the same manner, being sure to align it parallel to the driven element and centered as best as you can so that an equal amount from each end extends beyond the ends of driven element. It should be placed 1.4 meters 4'6" (1.4 meters) behind driven element for 0.13-wavelength spacing, or 9 feet (2.8 meters) for 1/4-wavelength spacing if you have the room for it. A slightly better front-to-back ratio will result. I had to use 0.13-wavelength spacing because of limited ceiling space, but it still provides overall good performance.

Now, check the VSWR again. You may find that it has risen from the last check, so trim the ends of the reflector element as needed, making sure you trim the same amount from driven element ends at the same time. Final VSWR checks run on the antenna at my QTH gave the results shown in Figure 3. Once you have gotten the VSWR down to an acceptable level, solder all four ends of the antenna and waterproof them if desired. This completes construction.

On-the-Air Results

Comparing the beam antenna to a coaxial dipole, there was a definite increase of 2 S-units, indicating a moderate gain of 5-6 dBd. Front-to-back ratio is not very much, so contacts off the back should be of sufficient signal strength for solid copy both ways. Should you desire to change direction of the antenna 180 degrees, you can convert the reflector element to a director element simply by trimming the ends so that it is 5% shorter in length than the driven element.

This is especially handy on 10 meters when winter European DX fades and summer South American DX predominates. If you like to experiment, a third director element 5% shorter than the driven element can be added for additional gain and front-to-back ratio. Or perhaps a 15 meter beam would appeal to you. Experiment! The possibilities are varied and intriguing!

With this antenna in use at my apartment QTH for over a year, I've been able to work many areas of the world with solid copy both ways that previously weren't strong enough to copy on the dipole for a QSO. Stations have expressed amazement or total disbelief about my antenna, but also provided some very interesting QSOs! Once you start enjoying the pleasures of DXing from your apartment or condo with an indoor beam antenna, I'm sure you'll raise many eyebrows, too! Happy DXing. ■

Economical Mobile HF Antenna

Modify a CB antenna for the ham bands.

by John Portune AA6NG

When you think "mobile HF antenna," what comes to mind? Big and ugly? If so, you're normal. Little wonder so many hams have turned, in just the last three decades, to the convenience of VHF and UHF repeaters. Yet mobile HF still offers many advantages. On long trips and in remote areas, it is unequalled for fun and safety.

I couldn't bear the thought of a gigantic loading coil, a ball and a spring, on my new, small car. Fortunately, I found an answer. This article describes that solution—a modified commercially-built, base-loaded CB antenna. It has proven itself remarkably efficient, as well as an attractive partner to my diminutive new car and modern mobile transceiver.

Perfect for Modification

The current model Radio Shack 21-908A Trunk Lid Mobile CB antenna ($26.95) is ideally suited for conversion to HF. It has a loading coil that comes apart, making it easy to rewind, and is shunt-fed, making it easy to match. This second feature is very important.

In the past, HF rigs had output tuning networks which could match the low impedance of a mobile whip. Today, however, many mobile rigs are "no tune." They must see a 50 ohm load to function correctly. An antenna, therefore, must not only be tuned, but also impedance-matched, before it can accept power from such a rig. The preferred way is to add an additional small shunt coil from the feedpoint to ground. The Radio Shack antenna has this feature built in. A ball-and-spring setup does not.

Since modifying the first of several of these antennas, I have operated them on most of the ham HF bands, and have rarely been disappointed by an unanswered CQ. The little antenna has proven to be a winner.

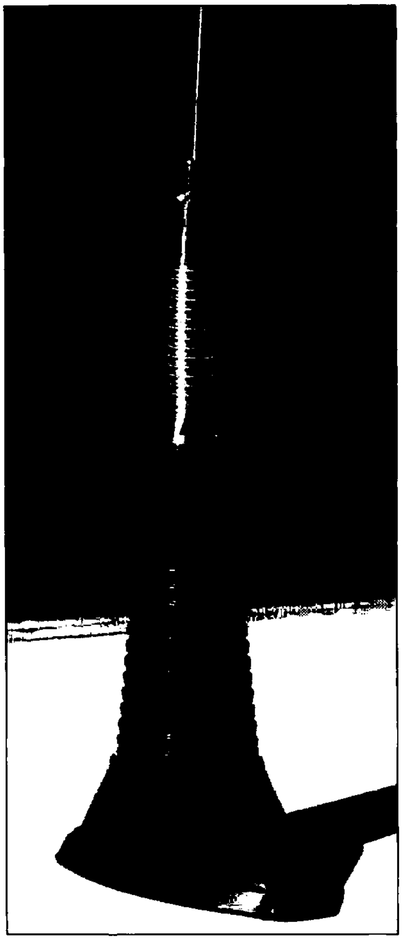

Photo A. This antenna is rugged, attractive, and easily mounted on the trunk lid. The whip may be adjusted in length by loosening the set-screw.

A Magnetic Mount Version

This same antenna also comes in a magnetic version, model 21-940. I had originally hoped to use it. But there is a problem. A magnetic mount relies on capacitive coupling to the car's metal body. It effectively adds (see Figure 1) a capacitor (Cm) in series with the antenna.

For 20 meters and higher, this is not a problem. But as the frequency gets lower, the reactance of this capacitor will eventually exceed 50 ohms. When it does, there is no 50 ohm tap point on the loading coil.

The trunk lid mount, with a real electrical ground, eliminates the problem. But if you are content with 20 meters and above, you

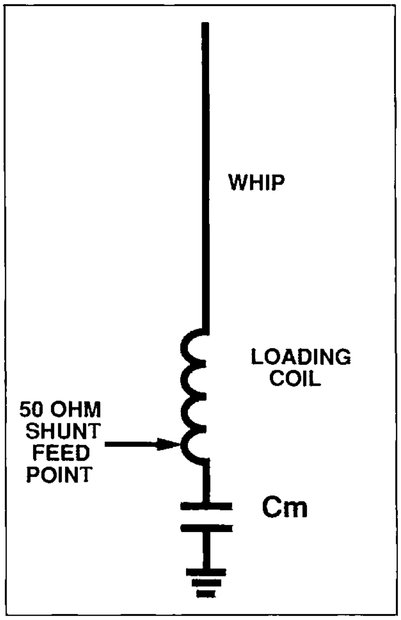

Figure 1. The circuit of the antenna on a magnetic mount. "Cm" is the effective capacity of the mount. At lower frequencies, the reactance of "C" exceeds 50 ohms, and impedance matching is not possible.

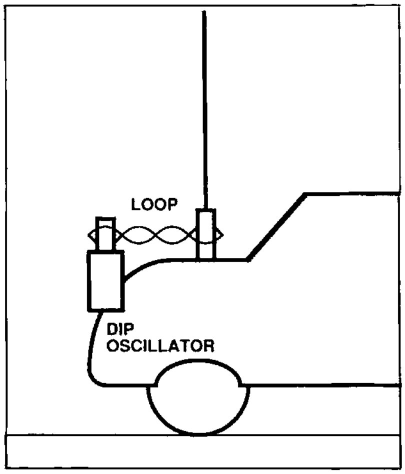

Figure 2. The resonant frequency of the antenna may easily be determined with a dip oscillator coupled to the antenna by a loop of twisted hook-up wire. Keep away from the antenna when dipping. The antenna feedline should be connected to the transceiver during the measurement.

may wish to use the magnetic mount. Some additional turns will have to be added to the coils, however, to counteract for the series capacity of the mount.

Modifying the Loading Coil

The loading coil is easily pushed out of the gray plastic housing for rewinding by pressing the threaded stud against a firm surface. Two well-placed O-rings protect the assembly from the weather. Be careful of these during modification, as they are easy to damage.

Notice that the coil has two sections. Tuning of the antenna is accomplished mostly by the upper coil, the impedance match by the lower. The feed from the center conductor of the coax is a shunt tap between the two coils.

The correct number of turns and wire gauge for each band is given in the table. The values are for the center of the band. Operation on 80 meters with this antenna is impractical due to the small diameter of the wire that is required.

You will also have to perform minor surgery on the plastic coil form. It comes with molded ridges to space the windings of the CB coil. For all but 10 meters, these should be removed with a coarse file or a hobby knife. A slight touch of the soldering iron will secure the new windings. Be sure to use the wire size listed. Also, wind all turns tightly together at the bottom. Different sizes of wire, or spaces between turns, will significantly change the number of turns required.

Tuning the Antenna

Once the completed antenna is assembled and installed on the car, tuning may be accomplished. This is not difficult, but it is touchy, owing to the size of the antenna. The smaller a loaded mobile whip, the narrower its operating bandwidth. Also, the bandwidth becomes more critical as the frequency goes down. On 10 meters the bandwidth is quite broad, but on 40 meters it is very narrow.

You will, therefore, have to slightly alter the number of turns on the loading coil for the specific spot on the band where you operate, especially on the lower bands.

A small amount of tuning is also possible during operation by adjusting the length of the whip. Use a turn or two less on the coil than for the frequency where you operate, with the whip all the way in. Then, by extending the whip, you will be able to lower the frequency to your precise operating point.

I leave a small SWR bridge in the feedline mounted near the transceiver. On low-power tune position, it is easy to find where the antenna is tuned—it's where the SWR is at a minimum. I then adjust the length of the whip until the antenna is perfectly tuned for my operating spot.

More Energetic Changes

If you wish to depart from the listed values more than a little, such as to build a version for a band not shown, you can use the help of a dip oscillator.

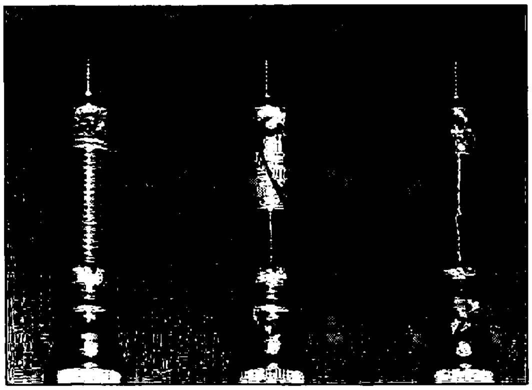

Photo B. Loading coils for three bands. Left to right are 10m, 20m, and 40m. Notice the spacing ridges on the 10m coil. Revolve these, and close wind coils for all other bands.

To do so, mount the antenna on the car and connect it to your transceiver (an open feedline will alter the operating frequency). Leave the gray plastic cover off of the loading coil during tuning.

Make a temporary coupling loop out of solid-conductor insulated hook-up wire, or from wire-wrap wire. See Figure 2. This loop will let you "dip" the antenna, to find its resonant frequency, without being too near it and changing its resonant frequency by body capacitance.

It is also a good idea to check out the test setup first with a known antenna, such as the stock CB version, before removing or adding turns.

First use your transceiver's receiver to verify the calibration of the dip oscillator on 10 meters. Then see if the stock antenna dips in the CB band (Channel 19 = 27.185 MHz). Then make a small modification to the coil. The dip oscillator will give you a fair indication of how far you have moved the resonant frequency. Repeat this process until you are inside the desired band.

You will then be able, using your transceiver and an SWR bridge, to locate the exact frequency that the antenna is resonant to. The SWR will be lowest at this frequency.

The necessary number of turns for the matching section of the loading coil is found by noticing how low you are able to get the SWR as you cross the band with a brief test transmission. Add or subtract a turn at a time until the SWR is near 1:1 at the resonant frequency of the antenna.

A Word About Power

Finally, be cautious about power. I use the antenna satisfactorily with an average 100 watt SSB mobile radio. But it is possible to exceed the power limitations of the antenna (the steady carrier power limit is 25 watts). The RF current in a short mobile antenna can be quite high, especially on the lower frequencies. Therefore, avoid more than brief key-down steady carrier situations. The loading coil could melt. Normal SSB voice transmissions will not be a problem.

An Attractive Compromise

Admittedly, from the purist's point of view, this little antenna lacks some in theoretical efficiency. A longer whip, a larger loading coil, or a capacitive hat would technically improve performance. But getting away from these is the object of the design.

By actual measurement, these changes would only offer minor improvement. To me, it's a small price to pay for the fact that I am one of the few in my ham circle who continues to enjoy HF mobiling in the days of tiny modern cars. The only drawback I've encountered is snide remarks from ham friends about a "good buddy" antenna on my car. They think I'm a traitor. I just smile and leave them in ignorance. ■

You may contact John Portune AA6NG at 724 Celestial Lane, Foster City CA 94404. If you request info, please include an SASE.

Turns Required on Loading Coil

Band	Upper Coil Turns (AWG)	Lower Coil Turns (AWG)
10m**	18 (*)	3.5 (*)
15m	21 (21)	3.5 (*)
20m	42 (21)	3.5 (*)
40m	82 (28)	5.5 (21)

*Existing AWG.
**Radio Shack recommends cutting the whip for 10m operation. However, the antenna will be more efficient if you rewind the coils according to this chart.

Number 9 on your Feedback card

DXDA '91
The Dynasty Grows . . .

73 *Magazine* welcomes the new members to the growing DX dynasty Award cadre! Special thanks to DXDA chairman Bob Reed WB2DIN for processing the results. Congratulations to all for a job well done.

73 Review *by Bill Clarke WA4BLC*

Carolina Beam

It's easy to set up, and it works great!

Radio Works Inc.
P.O. Box 6159
Portsmouth VA 23703
Tel.: (804) 484–0140; Fax (804) 483–1873
Price Class: 80-10m version $100; 40-10m version $90

Several years ago, I reviewed the Carolina Windom antenna. It was an excellent antenna for general use, and I've worked considerable DX with it and its cousin, the 160 Carolina Windom. The 160 lets me operate top band, as well as all the other bands. Of course, a tuner is required for all band operation with Windom type antennas.

In keeping with a fine tradition of well-designed wire antennas, Jim Thompson W4THU has introduced another innovative version of the Windom antenna. This new version has an updated, dedicated matching unit (balun), and bent wire elements.

Installation

The Carolina Beam is about as simple to install as any antenna I have seen to date. Just take it out of the package, clip a few cable ties, and unroll everything. It is completely built and you only have to attach the feedline, tie ropes to the insulators, and pull it into the air. My time was 20 minutes from "out of the package" to "on the air."

I do recommend that the end vertical legs be weighed down to keep them from moving in the wind. A one-pound lead weight will suffice nicely.

Coax-Seal™ is provided to weatherproof cable ends. Use it!

Performance

As standards for comparison, I used my 40/80 meter double-edged sword (a single feedline dipole with legs for 40 and 80 attached at the feedpoint) at 35 feet, and a 160 Carolina Windom (over 250 feet long) at 48 feet, in drooping configuration. Both antennas have been in place for over a year, and their performance on the bands is a known quantity.

I placed the Carolina Beam at 40 feet. Using good quality coax switches, I was able to make fast changes between the antennas.

My first observation was that the Carolina Beam hears as well as it talks. When a received signal was better on the Carolina Beam, the outgoing signal was better than that from the dipole or the Windom.

- •80 meters: As good as the dipole in all cases, and about 10 dB better than the 160 Windom for local work.
- •40 meters: Same as the dipole and same as the Windom.
- •30 meters: Same as the Windom in 90% of my contacts. Remainder slightly better.
- •20 meters: 50:50, with no clear winner. This is probably due to the distinct pattern differences between the Windom and the Carolina Beam. Having both to select from made a real difference in making DX contacts.
- •17 meters: In all cases, the Carolina Beam outperformed the Windom by 5 dB or better, except for one contact that was about 5 dB below the Windom (I really cannot say why).
- •15 meters: As with 20 meters, this band was quite variable.
- •12 meters: A distinct low-angle worker. The Carolina Beam always outperformed the Windom by at least 5 dB.
- •10 meters: Same as 12 meters.

Specifications
Length of horizontal portion: 84'*
Frequency: 80–10 meters
Radiator lengths: see diagram
Feedline: 50Ω coax
Wire: #14 stranded (7 x 22), hard-drawn
Matching method: DMU and transmatch
Power rating: 1500 watts
Minimum height: 30'*
Radials: not required
*The Carolina Beam can have the 32' element reduced to only 16' by changing the location of the support rope (the attachment insulator is factory installed on all Carolina Beams). This will increase the overall length to 100', but allow a lower height. Note: I didn't try this modification during the evaluation.

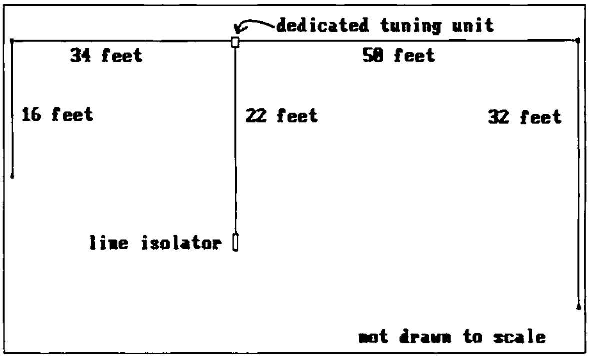

Figure 1. The Carolina Beam antenna.

It was interesting to note that there was little difference in signal reports from my station, compared to others using towers with directional beams (located near my QTH). The ionosphere is a great equalizer.

This antenna can be stretched out into a standard Windom configuration if you so desire. However, for the life of me I cannot understand why anyone would want to do it. By the way, Jim tells me the reverse is NOT true. Bending a standard Carolina Windom to look like a Carolina Beam will not result in Carolina Beam performance. The matching units are different.

How It Works

As with all Carolina Windom based antennas, the Carolina Beam is designed to create feedline radiation. This is induced by an unbalanced condition caused by the dedicated tuning unit. The feedline radiation is terminated by the line isolator to control the radiation pattern and to keep unwanted RF out of the shack. Thus, the coax feedline becomes a vertical radiator.

The horizontal portion of the antenna connects the three vertical radiators together and acts similar to a ground plane with inverted vertical elements.

Unlike trap antennas, the Carolina Beam radiates from all elements over the length of the entire structure on all bands. Because both vertical and horizontal elements are present, there is a good mixture of high and low angle radiation.

The Carolina Beam does require the use of an antenna tuner. However, most solid-state rigs require a tuner anyway to keep the SWR from shutting them down.

Pattern Plots

The radiation pattern plots accompanying this article were made

using the Carolina Beam installed at a 50-feet height over average ground. I used the ELNEC program for computer analysis, output to a Canon laser printer.

Azimuth plots are shown for the angle of elevation which gives the maximum signal (the angle is indicated at the lower right corner). Plots for the WARC bands are not included, as they nearly duplicate other nearby bands. The 75 meter azimuth plot was perfectly omnidirectional, and therefore is not included.

My Comments

I am impressed by the Carolina Beam. It is a small antenna that is able to stand up to much larger systems. The entire package is precut and ready to go in the air. It comes with a dedicated tuning unit, RF line isolator, insulators installed at all points, and a pre-made primary vertical radiator (coax).

While not really a beam in the sense that most hams envision, and not giving the directional performance that you expect from a 3-element tribander at 70 feet, the Carolina Beam is a very workable antenna. It does not cost near what a tower, beam, and rotor would.

The Carolina Beam will fit into a space just over 80 feet in length, and give full 80 meter dipole performance. This is something for the small-lot ham to think about.

The Carolina Beam is about as close to one antenna do-all as you will ever get. For those with very limited space, Radio Works produces a cut-down version of the Carolina Beam, which requires only 42 feet of horizontal space and covers all bands from 40 through 10 meters.

As well as a good choice for a home station antenna, I personally think the Carolina Beam and other Windom-type antennas, are excellent for Field Day exercises. They are certainly more convenient than towers and beams!

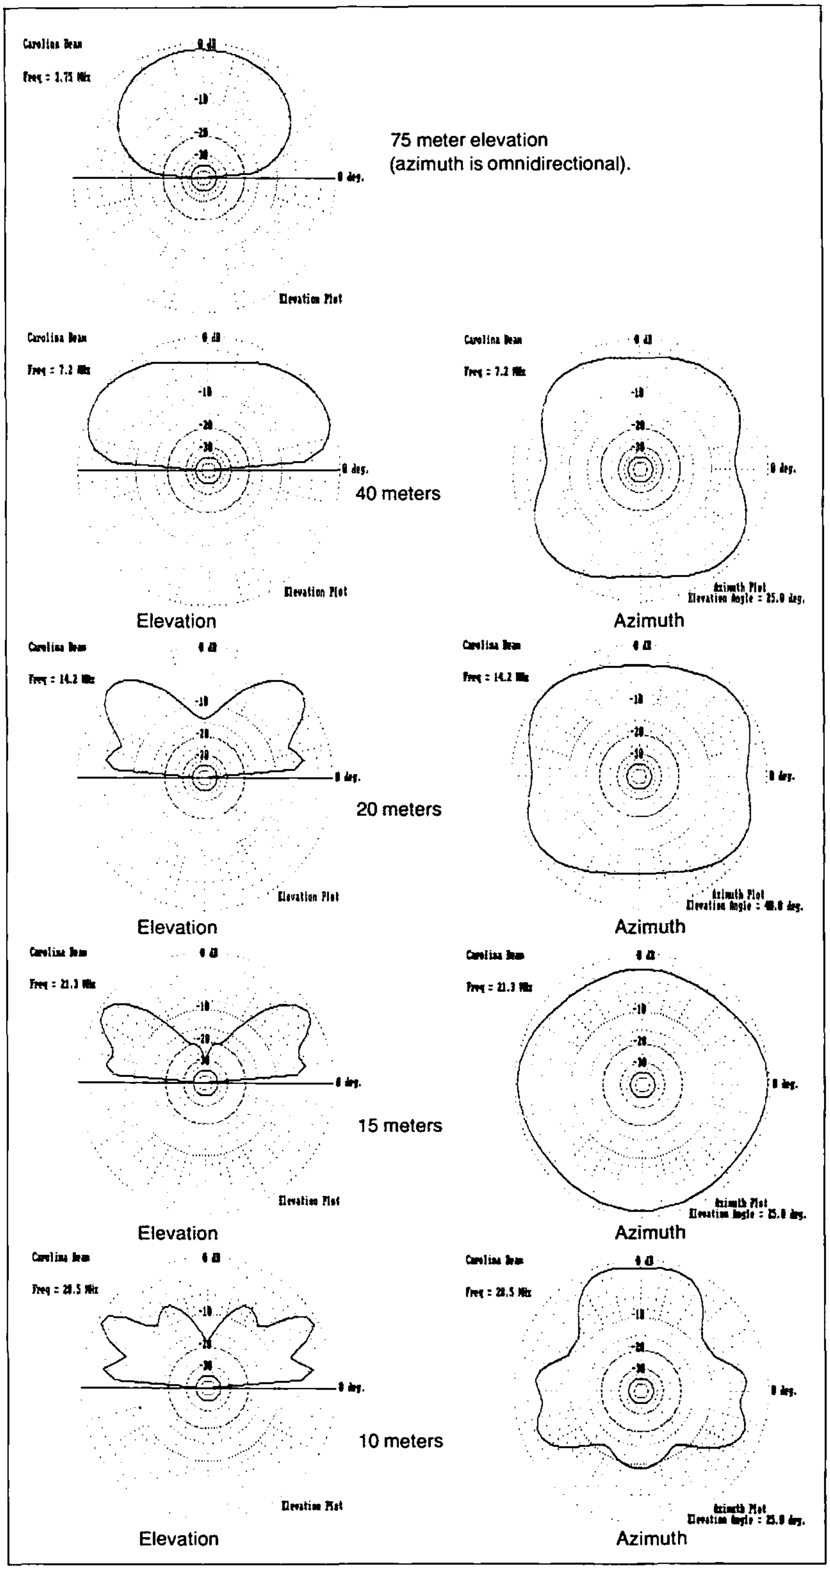

Figure 2. Elevation and Azimuth plots for the Carolina Beam.

Dual-Band Vertical

For the 160 and 1750 meter bands.

by David F. Curry WD4PLI

Using a TV push-up mast, you can get surprising ground wave radiation from small vertical antennas (30 to 50 feet high) for the 1750 and 160 meter bands. Good antenna performance is critical; the antenna must be resonant with your operating frequency for transmission, and have a good ground system.

FCC regulations state a maximum-50 foot limit in the 160 to 190 kHz bands for both the feedline and antenna. Even with strict limits such as these, transmission and reception of ground wave signals from several hundred miles away are possible at low power levels of only 1 watt.

Many amateur operators would like to try this low band, but they can't find a good design for an antenna. A 160 meter antenna could easily be matched to work the 1750 meter band, but its dimensions might exceed the legal limits. In this article, I offer a good compromise, opening opportunities for someone with space restrictions.

Antenna Description

The basic antenna assembly is in three parts: the top hat and 160 meter loading coil, the push-up mast upper and lower section, and the loading/relay system for antenna matching.

The capacity hat is the key to good radiation resistance and low angle radiation for 160 meters, and greatly improves the efficiency on 1750 meters. The size shown in the picture is 10 feet in diameter, with a wire ring around the perimeter. The wire ring further increases capacitance, adding to overall efficiency.

The telescopic portion of the antenna is a galvanized steel push-up mast you can buy at almost any Radio Shack, electronics or possibly hardware store. Select the length that suits your requirements. A 40-foot mast seems to be a good compromise of rigidity and height vs. price.

Final matching will be done at the antenna site, using a relay for dual-band operation (not required for single-band operation), and a capacitor/inductor combination.

On the 160 meter band, the antenna is current-fed by the loading inductor just under the capacity hat. The actual antenna resonance is lower than the frequency of interest, and therefore must be electrically shortened by a series capacitor at the base of the antenna. The capacitor should be preferably an air dielectric, such as a large transmitting variable from 50 to 500 pF. A vacuum variable

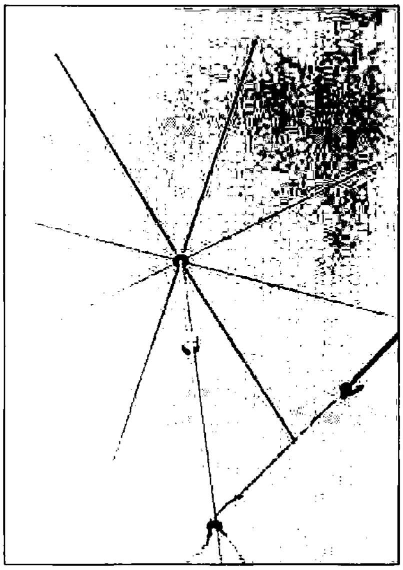

Photo. The dual-band vertical showing the capacity hat and top-loading coil.

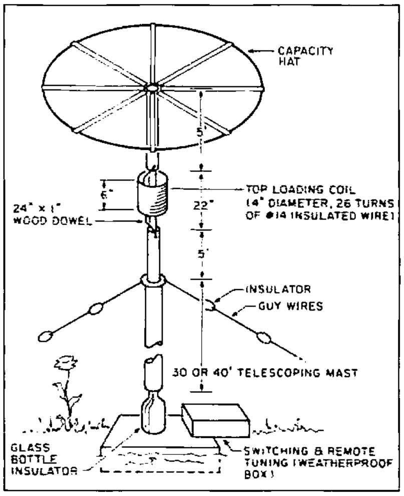

Figure 1. Overall dimensions of the dual-band vertical.

would also be ideal. The larger the tuning range of the variable, the greater the frequency swing across the 160 meter band. The capacitor connects between the antenna and the center of the coax lead, and is tuned for minimum VSWR. With the loading coil near the top of the antenna, most of the current will flow to the top, which is desired.

1750 meter operation is very different, as this antenna is extremely short at these frequencies. With the size of capacity hat described, a top-loading coil would be very inefficient due to the high amount of inductance required, and the subsequent I^2R losses from the resistance of the wire. A much larger capacity hat would be required, and would involve consulting your neighbors! Instead we will voltage-feed the antenna using a large prehistoric-size loading coil at the base, and use a tap point on the coil to match it to a low impedance source (transmitter).

By using the capacitive reactance to tune the coil to resonance as a part of the antenna capacitance, the coax actually becomes part of the antenna matching system. This offsets the 50-foot antenna and feedline restriction by turning the coax from a non-reactive transmission line to a reactive component that is part of the tuning circuitry.

The loading coil L1 in Figure 7a can be a regular air-wound inductor, with the number of turns found experimentally. Or you could use a variometer (see the sidebar) that would greatly ease the tuning procedure.

Construction

Remember before starting that the top loading coil just below the capacity hat can be eliminated if you plan to operate only on 1750 meters.

The capacity hat is made of eight aluminum tubes, each 5-feet long and ¼-inch thick, purchased at a local hardware store for about a dollar a foot (see Figure 2). At the end of each tube, press a ½-inch area flat with pliers, and drill a small hole to accommodate a

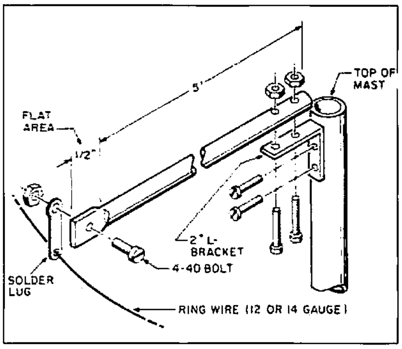

Figure 2. Construction details of the capacity hat tubes. A 2" steel L-bracket is used to attach each tube to the mast. Run a wire ring through the far ends of the tubes to form a large circle (solder the wire ring at the end of each tube).

H-T POWER FOR LIFE!

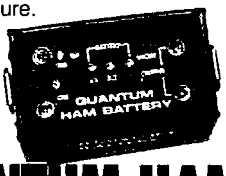
The Quantum Ham Battery™ may be the last rechargeable battery you'll purchase. Its 12 volt 2.1 **amp hour** capacity packs up to six times the power of H-T nicad packs.

A simple coiled cord connects Quantum's power to your H-T. If you buy another H-T just get another cord — without the additional cost of new batteries and chargers. The Ham Battery will power all sorts of 12 volt gear — past, present and future.

You'll always know how much power remains. The battery's status is continuously monitored by a unique L.E.D. display. Its sealed lead cells maintain charge for months and recharge reliably to 100% capacity without the "memory" effect of nicads.

You'll have the power you need when you need it — for emergencies, events, field day, camping, boating, camcorders, cellular phones ... even two at once with dual outputs.

Discover what so many other hams have already discovered: the ultimate solution for long lasting H-T power.



THE QUANTUM HAM BATTERY™

CIRCLE 26 ON READER SERVICE CARD

4-40 nut and bolt. Use a solder lug so that the ring wire can be soldered securely after the solder lug is tightly fastened with the nut and bolt to the aluminum rod. This makes it easy to install the wire ring. At the other end of each tube, attach a 2-inch steel L-bracket. Drill 8 holes equidistant around the top end of the mast pipe so that the capacity hat tubes can be attached. Mount each tube to the mast as shown in Figure 2.

When you attach the top hat, be sure to twist each rod so that the solder lug at the end will be in a vertical position. The wire chosen as the ring wire should be of large solid variety, and can be insulated. String the wire through each solder lug hole, but not too tight. Clip and solder the end of the wire, and each remaining solder lug, with ample solder. Spray your favorite color of paint on the entire capacity hat assembly for weatherproofing, or paint marine varnish over all sections.

The top loading coil for 160 meters is constructed from 4-inch diameter white PVC pipe, about 5 inches long. 30 turns of #16 gauge stranded wire, Teflon™ insulated, is used for the initial inductor. You could use other coil-form material, such as Plexiglas™. Avoid black-colored PVC tubing!

Wind the coil tightly and paint it with Fiberglas resin. Use solder lugs to secure each end of the coil, and 6-inch wires to connect the coil to the top and bottom mast.

The top section of the mast is five feet of galvanized steel tubing, exactly like the top section of the telescopic vertical. The exact length is not critical since the coil can resonate to almost any reasonable length, but lengths beyond 10 feet can break due to wind resistance. Three to seven feet are recommended. *[Ed. Note: If you use a 40 or 50-foot telescoping mast for the antenna, you can cut the top 10-foot section in half to use as the top section.]*

When painting the coil, also paint a wooden dowel rod that's about one foot long and fits easily into each vertical section. The idea here is to provide good insulation and solid strength for the top section of the vertical and capacity hat. The wooden dowel works very well for this, and should be inserted into the top of the push-up mast after curing.

Final Assembly

Now you may have to make a big decision. Shall it go on the roof or in the yard?? It should be in the clear as much as possible, of course! Absorption from trees and surrounding structures can foul up an antenna of this type. Also, you have to consider a ground system after raising the antenna. Insulated radials (as many as practical) at 50-foot lengths should radiate from the antenna base in equal directions. On roof installations, use either radials, hot and cold water pipes (especially copper ones!), or chicken fence mesh. Many times a combination of these will do an adequate job, especially for the city dweller.

After you've determined the antenna site, make preparations for the insulated base. Many approaches can be used, but the old glass bottle trick works every time, and is

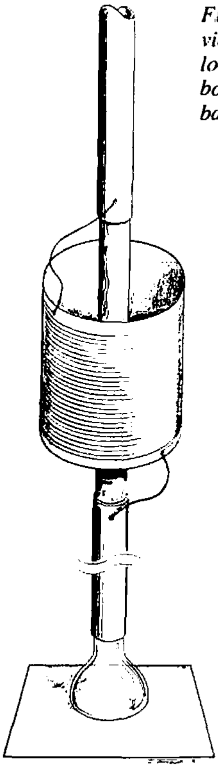

Figure 3. Close-up view of the 160m top loading coil and glass bottle insulator for the base.

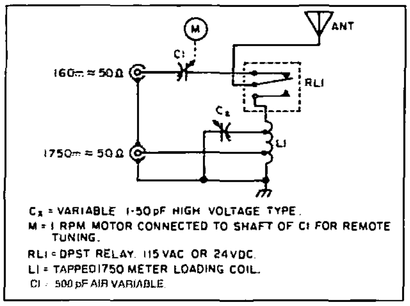

Figure 4. Switching arrangement for dual-band operation.

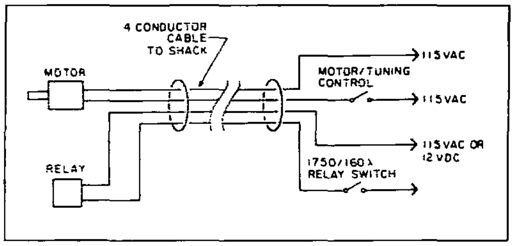

Figure 5. Cable connections for remote tuning.

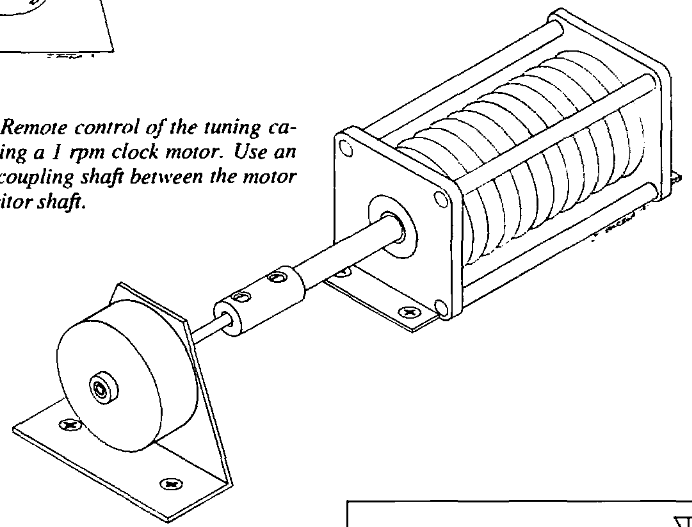
Figure 6. Remote control of the tuning capacitor using a 1 rpm clock motor. Use an insulated coupling shaft between the motor and capacitor shaft.



recommended. The bottle is simply placed in cement that has been prepared and drying. Insert the bottle about four inches into the cement. The cement may be poured into a hole in the ground, for ground installations. A vent pipe can be used for roof mount, but a strong solid insulator, such as a Plexiglas or Teflon rod, must be used as an insulated support. Plastic companies usually carry this product. Alternatively, a cement block can be used with a glass bottle for roof mounts. The guy cables are ¼-inch polypropylene rope which are adequate but need replacement every couple of years.

The collapsed mast is placed over the insulator and guyed at the 10-foot section. Additional guys are attached, usually at the 30-foot section.

If steel guy wire is used, be sure to use ceramic egg insulators, two per guy to insulate the vertical. Very high voltages exist

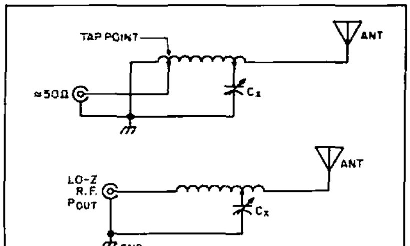


Figure 7. (a) Proper matching to 50 ohm coax. (b) Direct connection to the transmitter at the antenna site.

Variometer Construction

A variometer provides an easy way to match low frequency antennas, such as vertical radiators, random length horizontal, or "L" shaped wire antennas, and resonate these at a desired frequency.

A variometer can be thought of simply as two inductors that can slide in and out of each other. Depending on the size of the inductor coil forms, the number of turns, and the size of wire used, the inductance will vary as the magnetic fields of both coils either aid or cancel each other as the two coils are moved within each other's proximity.

One of the coils can be made small enough to rotate inside the larger coil, and the magnetic flux can be added or subtracted by rotating the inside coil. To do this, both coils must be connected in series. The variometer is wired so that the smaller rotating inductor is connected within the large outer one. Optimum efficiency will occur when both coils aid or add to each other for maximum inductance.

During initial calibration, after rotating the inside inductor to resonance, it may be beneficial to remove wire from the variometer. This is especially desirable from the standpoint of higher efficiency and better *Q*.

The whole point of the variometer is to find the ballpark resonance of your antenna system, then optimize the variometer by removing or adding turns, if required.

Assembly

First, wind the large coil form.

Usually, a range of 5–8 mH for a 30–50 foot vertical antenna will be within the 1750 meter limits. A vertical antenna such as this should also have at least a 5-foot capacity hat for improved radiation resistance. Wire gauges from 18 to 26 work well, with the small gauge wire providing more turns per inch and more inductance. Number 22 gauge wire does a fine job overall, and you'll need at least 200 feet.

Two small holes, one at each end of the coil form, is used for terminating each end of wire after winding.

Tape one end of wire with masking or Scotch™ tape to, or near, a hole at the end of the coil form. Sit in a chair or couch with the form in your lap. The spool of wire should be on the floor, leading up to the form.

Turn the form with one hand and use the other hand to guide the wire taunt against the form. A tight, even layer is required. After 20 or 30 turns you might want to stop and push the turns closer, if required.

Masking tape will hold the turns in place when you stop. In the middle of the form are two 1/4-inch holes directly opposite each other, with a small hole next to each one. Wind the turns carefully around these holes so that you don't block them, because the holes will be used later on in assembly.

A 4-40 screw with a solder lug can be installed at the end hole to terminate the wire. The insulation should be removed with fine sandpaper or a stripping chemical, and then inserted through the eye of the solder lug and twisted. Make sure that there isn't any slack that could loosen the turns of the wire. Repeat this procedure for the other end of the coil using a 4-40 screw and nut, and a solder lug terminal. If desired, a spray varnish can be used to add weatherproofing and protection. Use only a clear varnish or enamel.

Now wind the smaller coil form in a similar fashion. Because this form is so small by comparison, it may not be necessary to take the same precautions as before. The only major difference is the way the wire is installed in the form itself. (See the figure.)

At this time, varnish or spray enamel may be used to protect the inside coil.

The final step in the assembly is to install the small coil inside the larger one, and wire the two inductors together. Locate the nylon threaded rod and nylon nuts. Push the rod through one end of the large coil and screw a nut on. Turn the rod and advance the nut, then screw on another nut. After an inch or so, place the smaller coil form inside the larger one, and place the end of the rod into the 1/4-inch hole in the center of the small form. Continue to turn the rod so that it advances into the small coil form and add another two nuts on the nylon rod. Continue turning the rod so that it can go through the small coil form, and add one more nut. A total of six nuts are used, with four of them holding the smaller coil directly in the center. Tighten the nuts with FINGERS ONLY! The rod should extend completely through the large coil, with one end longer to provide a knob to turn it with. At this end, add the last nut on the outside of the large coil, and screw it so it is tight with the inside screw, centering the small coil and providing a small amount of friction so that the small coil won't slip.

Take the wires from the small coil and lead each wire through the small holes on the larger coil form.

These two wires should follow closely to the nylon rod, and have no kinks or twists.

Once fed through the small holes on the large form, clip the excess wire so that only 1/4 inch remains extending from the large coil form. Remove the enamel so that each wire is clean for soldering.

The diagram shows that the wire is first fed backwards out of the hole (A), and down the inside toward the center (B), and then outside with approximately 3–4 inches remaining. This remaining end will go through the small hole at the center of the large coil form later. With the wire at (A) and (B) installed, wind the form completely, being sure to leave an open space around the 1/4-inch holes at the end. Push tightly all turns so that the most wire possible can fit on the form. Before cutting any wire, add approximately two feet, after inserting the wire through the hole (C). Now, cut the wire and feed it through hole (C), down inside toward the center and through hole (D), to the outside.

At this point, cut the wire on the large coil, where it goes between the two 1/4-inch holes. This will be right in the middle of the coil, and will be easy to locate since it is a single wire in between the upper and lower sections.

If no varnish has been applied to the larger coil, you will need to add tape over the upper and lower sections so the turns will not become loose after you cut the wire. Each of the cut wires should be trimmed back and soldered to one of the wires from the inside coil. Snip the wires from the larger coil and solder, one on each side, to the 1/4-inch wires on each side from the small rotating coil. Allow a small amount of slack on the inside wires for rotation.

Operation

The variometer is connected between the ground systems and the antenna, usually with a tap point several turns up from the ground side that connects to the transmitter and/or receiver.

For systems involving only a receiver, simply rotate the small coil of the variometer at the frequency of interest and note a peak in reception. If there is no peak in signal strength, then it is entirely possible that resonance is occurring elsewhere. Remove turns from the top of the outer coil if required.

For transmitting purposes, remove as much wire as possible from the outer coil after the frequency has been determined and experimentation has located the variometer's point of resonance. Measure either the RF voltage across the 50 ohm load with an oscilloscope or RF voltmeter, or the RF current to the 50 ohm load. Note the value.

Monitor the radiated RF level and turn the variometer control to resonate the antenna. A receive monitor, field strength meter, or a small neon bulb placed near the antenna is useful for this. Antenna voltage can be very high. Avoid touching the antenna while tuning.

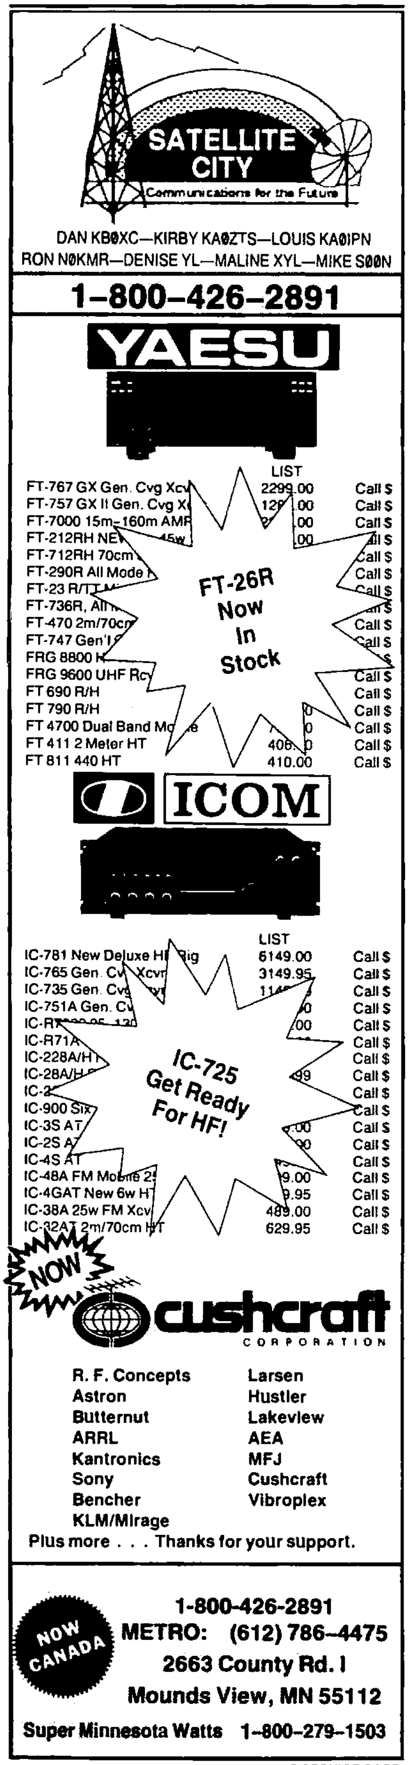
Note the current or voltage at the tap point. When the antenna is resonant, this should be the same value as that of the 50 ohm resistor. If the current is lower, go down on the tap point toward the ground end. For voltage measurements that are low, raise the tap point higher, away from ground. Re-resonate the antenna every time you change the tap point.

An optimum point will be reached where the tap point will have the same voltage and/or current, as was noted with the 50 ohm resistor, when the antenna is a resonance. Using a nonreactive 50 ohm load as a reference makes it very easy to adjust transmitters and antennas on 1750 meters.

Sophisticated equipment, such as an oscilloscope, is handy, but a small Ne-2 bulb will suffice in a pinch. Several Ne-2 bulbs soldered together in series will also work as a reference for monitoring voltage across the antenna. This is only for reference and does not indicate antenna efficiency.

Sometimes there may be difficulty in rotating the inner coil due to rubbing between the two. Adjusting the four screws that secure the inner coil will either expand or contract the coil center. Wire turns around the coil form sometimes warps the form slightly. Placing pressure will compensate for this. After this is done, set the two nuts on the outer coil form to gently hold the inner coil in the center.

A complete variometer kit is available (not including wire) for $68.95 postpaid from: Curry Communications, 852 North Lima Street, Burbank CA 91505.



CIRCLE 153 ON READER SERVICE CARD

when you use the antenna on 1750 meters, and high voltages exist on the capacity hat on both 160 and 1750 meters. You'll need a ladder next to the vertical, and rigid gloves to raise each section. Insert the wooden dowel with the top-loading coil placed about two inches above the mast.

With two small screws, bolt the coil to the side of the dowel. Clean the top of the mast in a small area. The wire from the bottom of the coil is soldered at this point. Place the top vertical and capacity hat section on the dowel rod, and clean it for soldering to the top of the loading coil. Raise the top section of the mast and tighten the section after being extended. Raise the next section and secure this after being fully extended. After all sections have been raised, check the guys and adjust the antenna into a vertical position.

You can add strength to the vertical joints by drilling ¼-inch holes through each joint and securing them with a nut and bolt through the smaller hole where the cotter pin is usually located. These masts can be quite flimsy when you're raising them. Be extra careful around power lines.

Loading Coil and Matching

Figure 4 shows remote switching and tuning of the antenna. A 1 rpm motor (M) is connected to capacitor C1 (Figure 6). Relay RL1, a power relay, will withstand at least 220 volts. This is required since high voltages exist with this type of antenna on 1750 meters. Using these will provide easy control right in the comfort of your own shack!

160 Meter Calibration

Connect an SWR meter between the transmitter and antenna. Place the transmitter into the transmit position, using low power in a clear portion of the 160 meter band that will be the frequency of interest.

Rotate the capacitor and notice the SWR meter for a dip. If no dip is indicated, try a lower or higher frequency. The top loading coil may need turns removed or added to facilitate tuning and lowest SWR. Capacitance of C1 lower than 50 pF should be avoided.

Poor ground systems will also deteriorate the lowest possible SWR. Shorting C1 will cause the antenna to resonate at its natural resonant frequency, which should be around 1750 kHz. The capacitor shortens the wavelength of the antenna into the 160 meter band, but a point of no-return can happen if the natural resonant frequency of the antenna is much lower than 1750 kHz.

1750 Meter Band Operation

Three to seven mH will be required to resonate this antenna on 1750 meters. A variometer (see the sidebar) is a convenient way to find resonance and match the antenna. Figure 7a shows proper matching to a coax, and Figure 7b can be used for direct connection to a transmitter at the antenna site. The coil in Figures 7a and b is tapped approximately five turns from the ground end, and can be found by simulating the tap point with a 50 ohm load.

Tune-Up

Transmit a signal on the desired frequency into a 50 ohm load and note either the current or voltage across to load. Replace the load with the tap point at the antenna site, and resonate the antenna by varying the inductance of the coil. Capacitor Cx is a 25 pF (value not critical) high voltage variable that is temporarily inserted to aid in finding the ballpark frequency resonance of the antenna, in case it's off-frequency. Cx should be removed or minimized for best efficiency. Adjust Cx and then add or remove turns on L1 until Cx becomes a very small value or not required at all.

Monitor the signal strength with a remote receiver or field strength meter. Figure 8 shows several neon bulbs soldered in series that are connected to the antenna. As the antenna approaches resonance, the bulbs begin to shine brighter. Once our aim, maximum brilliance, has been reached, note the current or voltage at the tap point. If there is a difference between this value and the value noted across the 50 ohm resistor, change the tap point and re-resonate the antenna. Do this procedure several times until the antenna is resonant and the SAME value is indicated at the tap point as with the value noted with the 50 ohm resistor.

This is the relative 50 ohm tap point on the loading coil, when the antenna is resonant at that specific frequency. The reactive element of the coax is absorbed by resonating the coil and antenna, providing a part of the total matching system. The direct coil method in Figure 7b can be used for beacon transmitters (for example), with the loading coil ground end connected instead to the transmitter output.

The loading coil can be made by using a large coil form, about six inches in diameter and 10 inches long, wound tightly with #18 gauge enameled wire. Plexiglas or white PVC tubing is excellent for this application. You'll have to experiment to find the exact amount of inductance required for antenna resonance. It is easy to accidentally resonant the antenna on the second harmonic. Check the signal with a receiver on both fundamental and harmonic frequencies to confirm power output on the fundamental frequency.

A car battery box (or any weatherproof enclosure) can be used to house the capacitor, relay and 1 rpm motor. The coil should be located in the clear with a coat of marine varnish after installation is complete.

Check out information on mobile 160 meter antennas for an understanding of how 1750 short verticals operate. They are very similar in principle. These short vertical antennas offer reliable results, and they're a good compromise of size vs. performance.

You may reach David F. Curry WD4PLI at 852 N. Lima Street, Burbank CA 91505. The owner of Curry Communications, David offers a variometer kit for this project for $68.95, postage paid.

The L-O-N-G Long-Wire

Helpful hints to build your own DX-buster.

by Stan Gibilisco W1GV

Many times on the air I have heard folks tell me they are using a long-wire antenna. When I hear this, I always wonder if they really do have a long-wire, or if they are just using an end-fed wire. At high frequencies, a true long-wire antenna requires some real estate. You might say that a wire is not truly "long" unless it exhibits noticeable gain and directional characteristics. Generally, this requires a length of two wavelengths or more, and at low frequencies this can be quite long!

Although it requires a lot of space, the long-wire antenna may be unobtrusive, and a good choice for the ham with a limited budget and an affinity for the lower frequency bands—20 meters and longer. This article describes the long-wire I put up, largely with the encouragement of local hams, and some hints for making things go as smoothly as possible. Murphy loves long-wire—there's so much to tangle up and snag—but he can be at least partly outsmarted. The obsessive/compulsive, hard-core antenna fanatic can win. With just one helper, I put up my 880-foot radiator despite a partly crippled right arm and wind chills considerably below zero Fahrenheit. Little things like that, and having to slither down a dangerously steep and slippery embankment, were not enough to intimidate an antenna fanatic such as myself.

Encouragement from the Net

Due to medical reasons, I had come back to Rochester to stay with my parents, whose home has great vantage points toward the north and west. A friend let me use his spare rig, an FT-101EE, and helped me put up a modest "long wire." This antenna worked well, but there was far more real estate available: an undeveloped piece of land measuring at least 800 by 800 feet (250 meters square). Why not put up a real long-wire?

But the land wasn't going to stay vacant; there was talk of it soon being bulldozed and built up. Besides, I'd be moving back out on my own in a few months. Putting up a long-wire would mean stringing 600 to 800 feet or more of wire. I was half-enthusiastic, thinking that the antenna might not last long.

But then, I thought, since when is anything permanent? One ice or wind storm can prove that no antenna is forever. If the antenna can be used for three months, that's three months more than no time. I decided not to fall for what I call "the impermanence excuse."

One friend on the local 10 meter net said he'd put up a real long-wire once, and had never regretted it; he encouraged me to go for it while I had the time and space. And so I did. Putting up an 880-foot long-wire was hard work, but it was worth it.

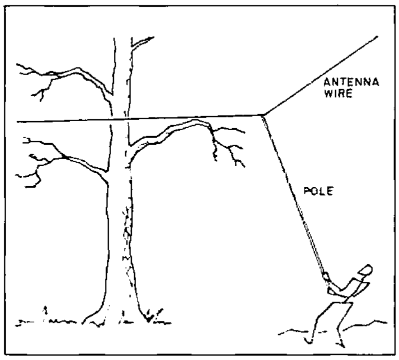


Figure 1. A long pole may be used to push the wire up higher when it is snagged on a tree.

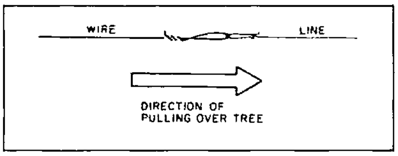

Figure 2. Attaching fishing line to the end wire with a "streamlined" knot minimizes the chance of snagging.

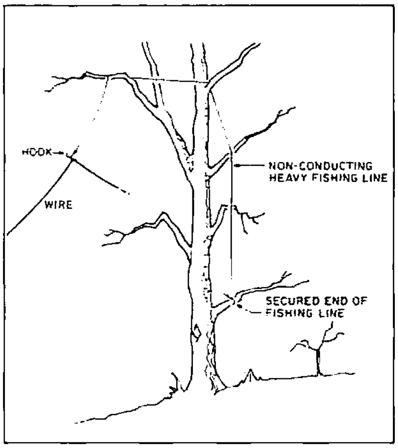

Figure 3. Raising the antenna wire as it passes near a tree may also be done if the wire gets snagged.

Snagaroo, and Other Goodies

If Murphy's laughs can be heard by madmen, there must have been a worldwide disturbance just before my first romp in the snowy, undeveloped land. The wire chosen was AWG #15 hard aluminum fence wire, available at a local farm supply store for $13.49 for a quarter of a mile (0.4 kilometer). Aluminum was chosen because it is almost as good a conductor as copper, but much lighter, and a far superior conductor to the steel wire also found in cheap abundance. As it was, steel would have been impossible to handle anyway; the stress on the wire was enough to pull me over several times.

It is truly remarkable how a twig as small and fragile as a toothpick can keep a gigantic, quivering, straining length of metal wire ground-bound against the efforts of one or even two men. If any passersby had heard my grunting and profanities on these numerous occasions, I'd have been committed straight away.

But vector physics provides a good explanation. The force of even 100 pounds of tension on a wire is nothing compared to one pound exerted laterally near the center of the span. Try pulling a long-wire as tight as you can, and then marvel at how, pushing it lightly in the middle with your little finger, you can displace it sideways several feet or meters. This principle was later used to advantage.

At first, though, I had to walk along the length of wire, free it from innumerable snags on bushes and small trees, pull the wire tight again, then trek along under it in the snow, tripping over small irregularities in the terrain and going down—poof—into the powder like a stuffed doll, muttering as I spit out snow and twigs. By this time it was too cold for loud swearing.

When the wire got caught in a branch too high to reach, I used a pole to push it up (Figure 1). The technique for very tall trees was to throw a line over the whole tree, or shoot it over with a bow and arrow—first watching out for kids playing or grownups hiking—and pull it up with a miniature grappling hook attached to the other end of the line.

Problems and Lessons

Using the bow and arrow method, we anchored the wire at its destination up over a tree. Here, Murphy had another golden opportunity to have some fun. Some problems that occurred were:

1. The wire snapped. I don't know how solid #15 gauge aluminum wire could break from less stress than my own body weight—140 pounds in full winter gear—but it did, somewhere up in the tree (of course), so that another weighted arrow had to be shot, the

MY GAP CHALLENGER DX-VI

Lew McCoy, W1ICP
CQ Technical Editor
(March 90 Review)

..."could actually hear signals that were in the noise on the beam. In my comparisons between the base-fed vertical and the GAP, the GAP consistently outperformed the base-fed antenna. Most of my reports were approximately one s-unit better with the GAP. One other surprise was that the GAP vertical was quieter (less noise) than the two base-fed verticals. I would rate the GAP as a quality product, but even more important a good performer."

Richard Morrow, K5CNF
73 Magazine
(October 90 Review)

"another very good thing about the GAP antenna is that you don't have to tune it. Usually broadband antennas are not very efficient, but this one is. If I could have only one antenna, I would definitely rather have this one. The lack of lossy coils, and the coverage of a very wide part of 75 meters by an all band vertical, impressed me more than a little!"

Kurt N. Sterba
Worldradio Magazine
(February 91 Review)

"These guys have solved a problem associated with verticals. That is, an awful lot of RF is wallowing around and dropping into the dirt instead of going outward bound. How does it perform? Like a hot knife through butter. I was just a barefoot boy answering the CQ callers. They just kept coming back to me. POW! POW! POW! I am almost struck with disbelief myself. I mean, this is a vertical. But then, it's a vertical with a big difference. I was indeed pleased. If I were a whole lot younger and I had two of those GAPs phased, I'd tell those contest hotshots to . . . look out!"

CIRCLE 172 ON READER SERVICE CARD

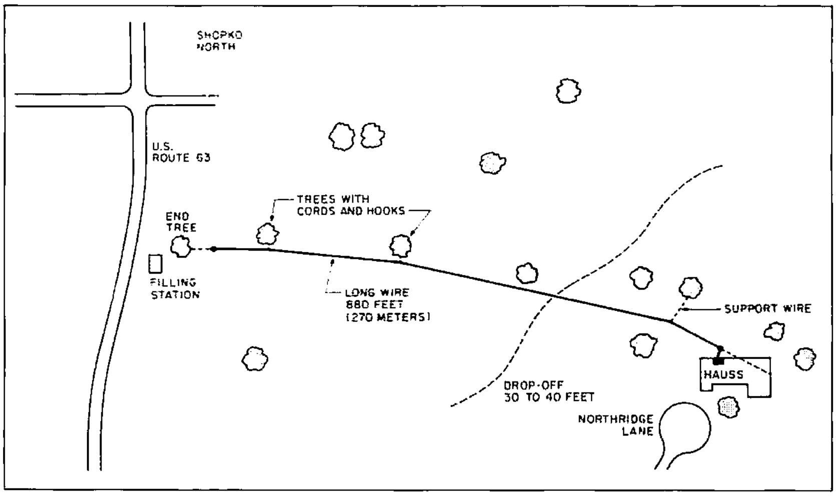

Figure 4. Map of long-wire antenna at W1GV. The wire runs in almost a straight line, an important feature for obtaining the characteristic directional pattern.

whole end insulator redone, and the wire pulled up again. *Lesson: Don't think that a wire won't snap.*

2. The wind blew the arrow off-course. Thus it did not catch the line in the highest part of the tree. *Lesson: Work when there isn't much wind (10 miles per hour or less).*

3. The arrow didn't have enough weight on it. It wouldn't come down where we wanted it to, or it wouldn't come down at all. *Lesson: Put enough weight on the tip of the arrow (a large stove bolt or two) so that the arrow will reach the ground.*

4. The fishing line or twine came off the arrow as it was fired. *Lesson: Secure the line to the arrow, and be sure the line is strong enough to take the initial tensile surge as the arrow is fired.*

5. The arrow was lost or got stuck out of reach. *Lesson: Bring two or three weighted arrows.*

6. The fishing line snagged on a twig with one ounce tensile strength, preventing a heavy, 50 mph arrow from even leaving the vicinity of the firing point. The arrow rebounded and struck the shooter in the face. *Lesson: Avoid snags and wear safety goggles.*

7. The end wire, or rope, snagged in the tree as it was being pulled over. This probable event should be anticipated. *Lesson: Tie a knot that is "streamlined" to reduce the snagging tendency (see Figure 2).*

8. The span was simply too long. At first I had planned to run a 1,000-foot (305-meter) single span of wire. I thought that the light weight of aluminum would make this possible, but the sag and tension were simply too great. *Lesson: Don't go for a single span; provide for intermediate supports.*

After all these lessons, the entire wire, including the lead-in, was finally up, with not a single splice. There were no joints to become corroded. It is very difficult to solder aluminum wire, so this was important.

Intermediate Supports

The wire ran near two large trees, and was snagged on a third one about 20 feet (6 meters) above the ground. The intermediate trees could have been used as supports by shooting weighted arrows over them, then pulling the entire long-wire through, but I was worried about tangling or kinking the wire. However, we figured out how to use these two trees for support, and unsnagged the wire from the third tree.

First, a weighted arrow was shot over the tree, using heavy braided 20-pound test line. Then a No. 4 fishing hook, the triple kind like a miniature grappling hook, was attached to the near end of the line, or the end that also was on the same side of the tree as the wire (Figure 3). The other end of the line was pulled until the hook caught on the wire, which it would *have* to do, having three barbs at 120 degrees apart. The wire was raised gently until the tension was deemed sufficient or the wire was high enough, then the line was secured to the bottom of the tree around a limb about an inch (2.5 centimeters) in diameter.

This technique allows for the wire to slide when the wind blows. It's not the strongest, most durable arrangement, but if it fails, the whole antenna won't come down. When dealing with an 880-foot long-wire, we must expect that eventually part or all of it will have to be restrung.

Finally the wire was connected to the transmatch and the grounding system was installed.

Grounding: DC and RF

Fortunately there was a cold-water pipe, copper with soldered joints, running through the wall right behind the rig. It seemed as though Murphy had slipped. It was difficult to believe this was possible, and my skepticism proved well justified. Oh, the pipe was there, all right, and was grounded for DC, as was evidenced by the shock I got when I made the mistake of touching it at the same time as touching the wire from the chassis of the radio, with the radio plugged in. As I breathed deeply and checked my pulse to make sure my heart was still beating, I recalled the old saying, "Never touch two grounds at the same time."

What smart-alec plumber put the RF choke in the pipeline? The ground did not work well at all for RF. On 40 meters, whenever the key was down, the receiver protection lamp lit up bright white on the back of the FT-101EE, and on 15 meters there was RF all over the house: The intercom picked up monkey chatter on SSB.

Any end-fed wire is bound to present problems of this kind. First, since the radiating part of the antenna comes right down to the station, there will inevitably be at least some "RF in the shack," even with a perfect grounding system. Second, the system is inherently unbalanced, and this makes a good ground mandatory. There are various ways to make the ground good, or at least fair, for RF. All of these techniques involve using resonant wires for each band to be used.

I installed quarter-wave, free-end wires for 10, 20, 40, 80 and 160 meters. The 40 meter wire worked as a 3/4-wave wire at 15 meters. The shorter wires were simply cut to the lengths as measured: about 8 feet for 28 MHz, 16 feet for 20 meters, 32 feet 8 inches for 7 and 21 MHz, 66 feet (20.1 meters) for 3.5 MHz CW, and 130 feet for 1.8 MHz near the bottom of the band.

The 160 meter wire was trimmed by tuning into it and pruning for minimum SWR at 1.810 MHz, the center of the desired operating range of 1.800–1.820 MHz. Surprisingly I had to trim about 7 feet from the wire to get minimum SWR at 1.810 MHz.

The ground wires were strung as straight as possible. This would, it was thought, enhance their performance as RF grounds, by maximizing the efficiency with which they would radiate the RF in the shack away. All these wires were tied together at the station and connected to the ground terminal on my MFJ-989B "Super Tuner V."

There was no evidence of any RF on my HF rig after the ground wires were installed. However, using a linear amplifier, some lighting of the receiver protection lamp was still evident on 160 and 80 meters.

Since I rarely use the amplifier, and in fact was only borrowing it for an upcoming 160 meter contest, I left the antenna perfection phase, and began the real acid test of finding out how well the long-wire would perform. I hoped for the best from a straight wire that measured 13 wavelengths at 20 meters, and 6.5 wavelengths at 40 meters, and was up 50 feet high. The wire was almost perfectly straight except for the lead-in, and I surmised that the major lobes would give a gain of about 9 dB on 20 meters and 5 dB on 40 meters. These determinations were made based on information in *The ARRL Antenna Book* (13th edition, page 165) and the *Radio Handbook* (22nd edition, p. 28.3, Howard W. Sams & Co.).

On The Air

The antenna runs west-northwest by east-southeast, or at azimuth 300 degrees from the house (Figure 4). Major lobes will be expected to run roughly at azimuth 285–315 degrees and 105–135 degrees on 14 MHz, with secondary lobes making these regions broader and closer in off the ends of the wire. On 7 MHz I would expect similar performance, with somewhat broader lobes. I was especially interested in VK6 and the Indonesia chain at 7 MHz, which I would listen for in the mornings.

The loudness of the VE7 stations was the first thing I noticed. One of them was even louder than a friend two miles away on a line of sight at 14 MHz. In fact, this VE7 is to date the loudest signal I have ever received on this radio, *bar none* (even the calibrator). He tipped the meter at S9 plus 37 dB, and while I do not regard most S-meters as absolute, this level qualifies as "S9" by anybody's standards. I worked several VE7 and VE6 stations, as well as loud W7s (who always seemed to be in Washington State), to verify that this antenna could radiate as well as receive in that direction.

Signals were also strong to and from W2 and W3-land, and southern New England, with W1AW code practice often as strong as the locals, both on 14 MHz and on 7 MHz. I rarely could hear any signals from Europe, although Africa was easy to get. The theoretical directional properties of an unterminated long-wire were being confirmed.

I have worked many stations now on 160 through 20 meters with this antenna. While it is a good performer and very inexpensive, all good things must end. The large tract of land on which the antenna resides is scheduled for development soon. More than anything, an antenna like this is a good conversation piece. It *sounds* awesome to say, "Rig HR 90 W output to 880 FT long-wire pointed right at U." The wire is almost invisible, and creates no eyesore. I use a grounding switch outside the window when the antenna is not in use; a long-wire picks up substantial static electricity and induced voltages from utility lines. If it happens to come down, I'll just put it back up again, maybe in a different direction just for fun. It would be possible to put up several different long-wires and switch them for work in various directions, and I probably would do it, too, if the property were going to be available longer—and if I were going to stay longer.

Conclusion

I thank the members of the local radio club who helped me with this project in cold weather. I am also grateful for their interest in the project and their putting up with my seemingly endless chatter about antenna theory on the local 10 meter SSB net.

If there is room for a true long-wire antenna, I'd say it is a good investment of time and money and effort to string one up and get on the air with it—for fun, if for no other reason. 73

UNEARTH YOUR FULL POTENTIAL
with the
CHALLENGER DX-VI
A unique multiband vertical that utilizes GAP technology.
The Challenger DX-VI covers all of
2m, 6m, 10m, 12m, 15m, 20m, 40m, and over 130KHz on 80m with a VSWR under 2:1!
It has NO . . .
• TRAPS • COILS
• BALUNS
• RESISTORS
• TRANSFORMERS
• BASE INSULATORS
The Challenger DX-VI Launches RF from a 16' elevated GAP, not from the base of the antenna. The antenna is PRETUNED. There is nothing to adjust. The Challenger DX-VI has virtually NO earth loss and requires only 3 wires 25' long which attach to the base of the antenna. Thus, eliminating the need for an extensive ground plane. The antenna is 31' tall and is self - supporting with a supplied drop in ground mount. No additional mast is required. Best of all the ENTIRE antenna is active on all bands and costs only $229.00*.

HAM - CB
COMMERCIAL

OPERATES
10 THRU 12 METERS
WITH TUNER

FIBERGLAS
OMNIDIRECTIONAL
BASE STATION
ANTENNA

• Covers far above and below the traditional C.B. Channels (for export, commercial and Ham band use, input 2000 watts, P.E.P.)
• The A-99 is a 1/2 wave voltage fed antenna that incorporates our patented variable mutual transductance tuning system.
•Comes in three sections. Easy To Assemble.
• Entire Antenna radiates 9.9 DBI Gain

TWIN RING
ADJUST-A-MATCH
TUNING

The A-99 features the Solarcon Twin Ring "Adjust-A-Match" tuning making it possible to tune the input to the antenna and obtain the optimum S.W.R. over a range of frequencies. Raising the rings raises the frequency and lowering the rings lowers the frequency.

Webersat Success

The microsat with the photographic penthouse, Weber-OSCAR-18, has been featured before in this column. Now it's time for an update. Recent pictures from the satellite of the earth, sun and moon are showing a definition and quality the designers only hoped for years ago.

Launched in January 1990 with three other microsats and two UoSATs from England, Webersat, as it's called at Weber State University in Ogden, Utah, is the second project undertaken by the Center for Aerospace Technology (CAST) at Weber State. The first was NUSAT 1 (Northern Utah Satellite 1), launched by the *Space Shuttle Challenger* in 1985. CAST continued with ambitious programs and teamed up with AMSAT to work on the microsats.

Webersat weighs 27 pounds. Its dimensions are 9" x 9" x 12.5". The unusual 12.5-inch height on one side is due to the camera and student-created experiments encased in the upper unit Most of the satellite is covered with solar panels. Within the satellite are six vertically stacked sections that communicate through a Local Area Network (LAN) bus. The lower five sections contain two 70 cm transmitters, a five-channel 2 meter receiver, the battery system and charge regulator, and a flight computer and digitizer system with logic support circuitry.

The uppermost module carries the color camera, a spectrometer, an L-band TV receiver, an impact sensor, a horizon detector, a command and control unit, a magnetometer, an FM modulator for low speed video transmission or synthesized voice with beacon messages, and an array of sensors for temperature, voltage, current and light intensity measurements.

While the scientific experiments on Webersat have been extremely useful for educational studies by schools around the world, the imaging and download system have been the highlight for amateur radio operators. The satellite takes pictures of the earth, or another celestial view, and transmits the image via phase-shift keyed AX.25 packets.

The camera is a modified Canon CI-10 CCD (charge-coupled device) unit with a 25mm lens using either programmable or automatic iris. When aimed at the earth, the camera sees an area 130 by 170 miles. The digitizer processes the video from the camera, then sends the image data to memory for downloading via the packet transmission system. Up to 12 pictures can be stored in the two-megabyte memory. Each image can be as large as 166,000 pixels (individual picture elements or dots on the screen). While the data can be downloaded to the earth via the FM modulator, it is usually sent by the packet radio system.

Hardware and Software

To receive the images, a station must have a PSK demodulator hooked to a Terminal Node Controller (TNC) and a computer capable of receiving the data and storing it. For those already on packet, the move requires a PSK modem and a 70 cm sideband receiver with input lines (microphone up/down buttons) allowing digital frequency control. Modems are available from PacComm, the Tucson Amateur Packet Radio Corporation (TAPR), Radiokit, L.L. Grace, and Advanced Electronic Applications (AEA).

Although directional antennas will help collect more picture data on each pass, they are not absolutely necessary if a good GaAsFET preamp is available with an omnidirectional home-station antenna. Antennas currently in use for local FM operation should be tried before purchasing or building a larger or more complex system. The primary downlink frequency is 437.102 MHz and the secondary is 437.075 MHz.

A PC compatible computer with EGA or VGA graphics, along with appropriate software, is required to collect the picture data. First, put the terminal node controller (TNC) in the KISS mode with the command KISS ON followed by RESTART. Use a data collection program like TLMDC version 3 (available as free software on many BBSs) and follow the instructions included with the program. Normal data and messages will be displayed on the screen during a pass while the raw picture data is stored in a file.

WEBERWARE 1.1 from Weber State University, available from AMSAT for $30.00, decodes the raw picture files and merges data. It takes at least two passes to get a complete picture, since even picture lines are sent on the first orbit, and odd lines are sent on the next. Work has begun on a new version of WEBERWARE, but it may be as long as a year before it becomes available.

Other individuals have produced ex

perimental software to provide the maximum resolution available from the Webersat imaging system. The photos show super-VGA images created using a very early version of WEB1 by Franklin Antonio, author of the very popular Instant Track satellite tracking software. The program only works with high-resolution systems and currently requires picture data previously merged and filled in by Weberware to get finished pictures. Plans are underway to begin beta testing of WEB1 sometime before the end of the year.

Before Webersat was launched, many pictures were taken, stored, and transmitted from the satellite. These pictures were of buildings and scenes around the Weber State campus. When viewed with either WEBERWARE or WEB1, the pictures show very good detail and contrast. Many of the early shots from space did not. They appeared grainy with bad exposure and contrast. Many hams lost interest in the picture packets from space.

Attaining New Heights

On August 15, 1990 the controllers at Weber State successfully took a picture of the sun. (A WEBERWARE version of the image was presented in the December 1990 "Hamsats" column.) Within a month, better earth views were also being taken.

In March, the controllers began shooting pictures in the dark, and caught the moon. The camera specifications did not indicate that this would work, but it did. Although it is difficult to see, the moon appeared as a crescent in the upper right-hand corner of the photo (not shown) that I was able to take from the monitor screen.

The earth view of April 14, shown in Photo C, is an example of some of the earth views currently downloading from Webersat. The resolution looks more like a commercial weather satellite, rather than a $10,000 amateur device built by students.

Unlike commercial satellites, views of other parts of the sky are possible with W-O-18, and experiments to try new ideas with the imaging equipment are encouraged. Weber State began testing systems in June for possible imaging experiments in July during the solar eclipse. All the onboard memory was used to collect image data in hopes of catching views of the sun and earth during the eclipse.

More experiments are expected from the team at Weber State, and further software developments are hoped for. More information on W-O-18 is available in a recently released manual created by CAST and sold through AMSAT. Although the manual doesn't have the data necessary to write picture processing programs, it does provide plenty of general data on the satellite and its many experiments and capabilities. Call AMSAT at (301) 589-6062, or write P.O. Box 27, Washington, DC 20044 for more details. ■

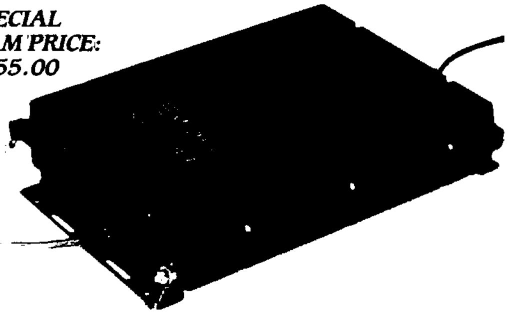
SGC SG-230

SMARTUNER

HF ANTENNA COUPLER—SSB, AM, CW & DATA
FAST—INTELLIGENT—ACCURATE
OPERATES WITH ANY HF TRANSCEIVER

The *Smartuner* high technology coupler intelligently tunes any length antenna (8 to 80 ft) in the HF band. This unit will operate with any HF transceiver within its' specifications. The *Smartuner* switches 64 input and 32 output capacitance combinations plus 256 inductance combinations in a "pi" network resulting in over a half-million different ways to ensure a perfect match for the transceiver. And, *it remembers the frequency and the tuning values* and will re-select these values in less than 10 ms next time you transmit on that frequency.

SPECIAL HAM PRICE: $555.00



Gordon West, WB6NOA, "the Smartuner is the best coupler I've ever tested or used"

- •MICROPROCESSOR CONTROLLED
- •NON-VOLATILE MEMORY
- •WATERPROOF
- •B.I.T.E. INDICATOR
- •1.8 TO 30 MHZ RANGE
- •10 TO 150 WATTS INPUT POWER
- •10 MS RETUNING TIME
- •8 TO 80 FT. ANTENNA (ALL TYPES)
- •FOR MARINE, AVIATION, HAM AND PARA-MILITARY APPLICATIONS

The SG-230 Smartuner is available from: *Amateur Electronic Supply, Milwaukee, WI 1-800-558-0411 Eli's Amateur Radio, FL 305-525-0103 Gordon West Radio, CA 714-549-5000 Surplus Sales, NE 402-346-4750 Jun's Electronics, CA 213-390-8003 Henry Radio, CA 213-820-1234 Ham Radio Outlet, Danville, CA 415-831-1771*

Parts!

Selecting them, finding them, buying them, substituting them, even recognizing them—parts are where it's at! Equipment is, after all, just a collection of components, all wired together to achieve an end. Sometimes, however, parts can be a big pain in the dummy load, because they may be hard to find, or their markings may be cryptic or nonexistent. Let's take a look at managing parts problems.

Although some repair jobs can be accomplished without new parts, many cannot. If you have or can easily get what you need, great. But real life seldom works like that, especially in electronics. When you need a new component and can't get it, the first thing to consider is the original part's function. Was it part of a critical circuit like a balanced mixer? Or was it a simple DC AGC amp, or perhaps a switching circuit? Once you know what is called for, you can make some intelligent decisions regarding a reasonable substitute. The process varies according to the type of part required, so let's look at a few:

Resistors, Resistors

If the original resistor was a standard 5 percent type, the circuit probably was not too critical, and any standard resistor of the same value (or nearly so, if you must wire multiple resistors together to get one close), and the same or greater wattage rating, should work. Of course, be sure to fix whatever malfunction was pulling too much current through the old resistor before inserting the new one, or you'll just fry that one, too. Resistors do not burn up on their own—something else takes them out.

Never use a wire-wound power resistor when the old one was a composition type. Wire-wounds are basically coils, and they do have significant inductance. Even in DC power supplies (especially switching supplies or switching regulators), they can wreak havoc. Of course, if the original part was wire-wound, then it's OK to use the same type. Usually, you can substitute a composition resistor for a wire-wound (as long as the new part can handle the power dissipation), but there are odd exceptions in which the designer used the inductance of the wire-wound resistor, or at least compensated for it elsewhere. If you're not sure, just replace the resistor with the same type and all should be fine.

If the original resistor was a high precision type, you must replace it with another high precision resistor. Those things cost extra (although not a great deal), so manufacturers use them only when necessary. You can be sure that circuit performance will be significantly affected by an out-of-tolerance part. For that matter, some circuits may require realignment even if you use the correct part.

Note that even if you find a standard 5 percent unit that measures within the tolerance of the high precision part, don't use it. The drift and thermal characteristics are looser on the standard part, and it may drift out of tolerance over time. Precision resistors are available at many mail-order outfits, and they don't cost a lot anyway.

Can You Read Me?

How can you tell if a resistor is high precision or not? If it has four color bands and the last one is gold or silver, then it is a standard 5 percent part. If it has five color bands, then it is a 1 percent part. On these, the value is represented in the same way as for standard parts, except that one more digit is specified. For example, a 1k ohm 5 percent resistor reads brown, black, red, gold. That's 1, 0, 00 and gold for the tolerance. A 1k ohm 1-percent part would read brown, black, black, brown, brown. That's 1, 0, 0, one zero and brown for the tolerance. It sounds hard but, once you get used to it, it's not much different from reading standard parts.

By the way, the standard resistor tolerance back in the tube days was 20 percent! Those resistors had no tolerance marking, so they only had three color bands. Then came 10-percent parts, which had a silver band. In modern gear, though, I doubt you'll see anything looser than the gold-banded, 5 percent units. Naturally, it's fine to replace a looser-tolerance part with a better one.

Let's Cap It

Capacitor substitution is much more complicated. Caps come in many forms, and each one has its own characteristics. As with resistors, first determine the function of the original part. If it was a simple bypass cap, darn near anything will work fine as long as the value is in the ballpark and the voltage rating is as high or higher than the original's. Same goes for coupling caps between audio stages. If, however, the cap was in a tuned circuit, you had better use the right part or a better one.

Caps come in many flavors. There are ceramic, polyester, polystyrene, polyethylene, mica, metalized film, metalized polyester, tantalum, aluminum, paper, and a few more which slip my mind at the moment. And within each group, there are subgroups. Ceramics, for instance, may be NPØ, which means "negative/positive zero." This refers to the drift with temperature, and specifies that the cap will neither increase nor decrease its capacitance value as it warms or cools. NPØs are most commonly found in tuned circuits, as they are overkill in bypass and coupling applications.

If a similar-looking ceramic cap says "Z5U," "N750," or some other number in addition to its value, don't use it to replace an NPØ; drift will result. In most cases, it is safe to replace a lesser-quality cap with an NPØ, but even this is not always true. I have seen occasions where a cap with a specific thermal drift characteristic was used to compensate for other parts' drift in the opposite direction! To be safe, in a tuned circuit always use the same type cap as the original.

Plastic caps of the "poly" variety are very stable, and their true values fall quite close to their stated ones. It can be hard to tell which variety you're looking at, because most of them look the same—like a small, rectangular green case with two leads sticking out the bottom. Generally, the size is a giveaway; if you can get the same value in the same size, it is probably the same type! Luckily, most circuits are not critical enough to care which kind you use, but there are exceptions. If in doubt, try it—you won't blow anything up. The worst that might happen is some drift or substandard performance, which you can remedy with another cap.

Tantalum caps are quite common these days because they offer lots of capacitance in a very small package. They're used in power supply, audio and coupling applications. In my experience, they are quite prone to shorting out. If you find a bad one, be sure to replace it with another tantalum part. Because of the high capacitance values, your only other choice would be an aluminum electrolytic, and those have much looser specs than tantalums.

Like normal aluminum caps, tantalums are marked with + and - and are polarity sensitive; be sure to put the new one in the right way around! If you install one backwards and apply power, discard it and use another, even if it still seems to work. Tantalums just won't stand reverse polarity, even for a second, and that reversed cap will fail in short order.

Aluminum electrolytics are those largish cans you always find near power supplies and in audio stages. They are pretty failure-prone, but they are easy to get. Normally, they are polarity sensitive and, like tantalums, are marked with + and -. There's an exception, though. Non-polarized aluminum caps are used in AC applications like hi-fi speaker crossover networks, and they cannot be replaced with normal electrolytics because the alternating polarity will destroy a polarized part.

Non-polar caps are usually marked "NP," and they never have + and - on them. They're a bit harder to find but, should you need one, you usually have no choice because no other type of cap has high enough capacitance without being polarized. If the NP cap is of fairly small value, you may be able to get away with using other non-polar types. For instance, I recently replaced a 3.9 µF non-polar cap in the horizontal sweep section of a computer monitor with four 1 µF polyester caps wired in parallel. The voltage rating of the new caps was high enough, so I tried it and it worked fine.

Speaking of voltage ratings, always remember that you must *never* replace an electrolytic cap of any kind with one that has a lower voltage rating. Manufacturers typically use parts with ratings 50 to 100 percent higher than the intended applied voltage. Use of a lower-rated component is likely to result in premature failure, and use of one with a rating lower than the actual applied voltage will quickly result in smoke!

It Gets Crazier

Substituting semiconductors gets really wild, because there are so many kinds. Diodes, transistors, FETs, MOSFETs, linear ICs, digital ICs, TTL, LSTTL, CMOS . . . there's just no end to the variety of what you might find in today's rigs.

In years gone by, manufacturers were forced to make their gear from "off the shelf" parts, which made it easy to find replacements. The increasing complexity of today's rigs, combined with the Japanese financial structure's willingness to commit to special purpose parts (a key element of that country's tremendous success), has created a trend of custom components.

You just can't build a camcorder or a 3 x 5-inch computer-controlled walkie from off-the-shelf components! Especially in the digital sections, manufacturer- and even model-specific chips are the rule.

Chipping Away at It

Luckily, those custom ICs rarely go bad. I have seen blown microprocessors (lightning cases) only a few times in my entire electronics career. If you do have a bad custom chip, you must go to the manufacturer for a new one. Even in the case where, say, a Matsushita or NEC microprocessor was used in another maker's product, that seemingly "standard" part probably has a suffix on its part number, which indicates that it has some specific ROM code built into it. Another "identical" part, but with a different suffix, won't work.

Sometimes, chips which may at first glance appear to be custom really aren't. Many standard ICs, with standard part numbers, are disguised by extra numbers and letters tacked onto the "standard" designator. The extra characters are used to identify the specific maker, case style, temperature range, etc. For instance, a D4011BC, a CD4011BCN and an MN4011B are all the same part, in this case a 4011 CMOS quad NAND gate worth about 25 cents. But if you order that part from the rig's manufacturer, you'll probably pay 10 to 100 times its true value and wait quite a while to get it!

The only way to recognize the standard designators hidden in part numbers is to become familiar with the generic numbers used for different families of ICs. For instance, standard "low-speed" CMOS parts use the 4XXX code, while low-power Schottky TTL is specified by 74LSXXX.

We'll continue this next month, and wrap it up with the names and addresses of as many of the major parts sources as I can find. See you then! ■

DARA Balloon

When launching ATV balloon experiments, the careful choice of a launchsite has a direct bearing on your success. The Dayton Amateur Radio Association (DARA) found the ideal location to fly their ATV balloon experiment: an actual weather bureau radiosonde installation just northeast of Dayton!

Permission was granted to use the facility after the morning radiosonde launch. Two radiosonde balloon flights are made each day (7 a.m. and 7 p.m. EDT) from the Huber Heights location (see Figure 3 on p. 31 of the August '90 issue of *73* for a map of U.S. radiosonde sites). The radiosonde transmits a series of telemetry tones on 1680 MHz which are decoded at the ground station computer (altitude, temperature and humidity). An 8-foot dish in a radome on top of the inflation building (see Photo A) tracks the balloon during its flight to indicate azimuth and elevation to within 0.01 degree accuracy. The ground computer uses this data to calculate wind direction and velocity at various altitudes which are used for pilot winds aloft forecasts. Those of you with a receiver that tunes this frequency in wide-band FM mode can listen in to these signals (the ICOM R-7000 and the ACE AOR-3000 has been used successfully).

Liftoff

Tom White, who works at the facility, launched the radiosonde at 7 a.m. as the DARA group was setting up for their flight. Tom's advice and help during the DARA flight was invaluable (he's launched well over a thousand weather balloons in his career!).

As the radiosonde was parachuting back down, the DARA group assembled their ground station and started filling up their balloon. Usually just the significant levels of radiosonde wind data are available at the FAA. Since we were at the actual site, all of the data was available so we could crunch it through the BALLTRAK tracking program. As a result, the computer prediction came within 300 yards of the actual touchdown!

Everything was on schedule for an on-time liftoff. The balloon was nearly inflated and the payload was ready. It looked like a picture perfect liftoff was in the making. As Dave Pelaez AH2AR/8 was inflating the balloon, he paused to smile for the cameras. His smile quickly changed to a frown, when a large POP was heard! The balloon had burst due to a flaw and flopped down on the table in a useless pile of rubber.

Fortunately, another balloon materialized and there was just enough helium (with a hydrogen assist) to fill another one. Although this balloon looked very distorted with a clear bubble on top, it survived liftoff and flew to over 86,000 feet.

Photo A. The DARA group inflates their first balloon in front of the radiosonde launch facility in Huber Heights, Ohio.

The Payload

The video section of the payload consisted of a Uniden VM-100 TV camera, a P.C. Electronics KPA5-RC 1 watt transmitter and a High-Technology Flight telemetry computer board with video overlay display (on-screen display of the W8BI callsign, temperature and altitude). A Hamtronics TA-51 two meter FM transmitter (modified for 100 mW output) sent out a digitized voice message on 144.34 MHz (Rainbow Products voice digitizer). In addition, a 1-watt CW transmitter (Ramsey QRP-20 with a GLB-2 CW ID) on 20 meters (14.035 MHz) sent out a message to the world. Since the Indianapolis Foxhunters were chasing down this package, I decided the recovery chances were good, so I risked my 35mm film camera which we piggy-backed on the side of the payload (it has now survived three trips to the edge of space!).

Photo B. The W8BI balloon ready for liftoff

The Flight

Great views of the suburbs of Dayton were seen via the downlinked video for the first few minutes. Since it was a hazy and fairly cloudy day, very little could be seen except for the telemetry overlay after the balloon passed through several cloud layers. Occasional views of the horizon were seen near the top of the flight.

Snow-free video was seen out to over 200 miles away. The 2 meter and ATV signals covered a good deal of the Midwest (a 400-mile plus range) at peak altitude (from Niagara Falls, Ontario to Iowa).

Touchdown

The upper level winds were very light. The weather bureau radiosonde travelled just 11 miles and landed very near the skycrapers in downtown Dayton. This had us a little worried (nothing like recovering a payload dangling from the top of a 50-story building!) Fortunately, the DARA balloon didn't go up as high as the radiosonde and parachuted down just east of the city in the open countryside. The Indianapolis foxhunt team kept under the balloon throughout its journey. Veteran balloon hunter Larry Oaks WB9YAJ told us his secret: "I just charge directly at the balloon at all times during its flight." This technique apparently paid off. Spectacular views of the highway and the suburb of Kettering were received by the chase team as the payload descended through the cloud layer at 1000 feet. The foxhunters closed in on their prey. Tom N9DZJ called in that he was very close to the payload but couldn't see it (it was 200 feet directly ABOVE his van). Larry WB9YAJ was about 200 feet behind Tom and actually saw the package parachuting down. If there hadn't been another car in the way in front of him, he

Photo C. A picture perfect takeoff. The balsa wood fin really helped prevent the payload from spinning

could've jumped out of his car and caught it before it hit!

Paul W9DUU and Chuck WB9IHS were in the car just behind Larry. They had an ATV downconverter and VCR in the car and videotaped the actual payload footage of the landing. It was great watching the final moments as the package narrowly missed a warehouse roof, bounced off of a tree limb and landed in a yard just 10 feet from the road. The package landed with the TV camera pointing up at the treetops. Shortly after landing, it showed the smiling faces of the chase team waving into the lens!

Although the 35mm film camera froze up after 60,000 feet, some great shots of the clouds were taken up to that point.

The DARA group had such a great time with this first flight that they plan another flight at 9 a.m. on the morning of October 6. For more information, check into the launch information net on 7.258 MHz (MIDCARS) just prior to liftoff. 73

AMATEUR TELEVISION

SMILE! YOU'RE ON TV

Only $329

Designed and built in the USA
Value + Quality from over 25years in ATV...W6ORG

With our all in one box TC70-1 70cm ATV Transceiver you can easily transmit and receive live action color and sound video just like broadcast TV. Use any home TV camera or VCR by plugging the composite video and audio into the front VHS 10 pin or rear phono jacks. Add 70cm antenna, coax, 13.8 Vdc and TV set and you are on the air...it's that easy!

TC70-1 has >1 watt p.e.p. with one xtal on 439.25, 434.0 or 426.25 MHz, runs on 12-14 Vdc @ .5A, and hot GaAsfet downconverter tunes whole 420-450 MHz band down to ch3. Shielded cabinet only 7x7x2.5". Transmitters sold only to licensed amateurs, for legal purposes, verified in the latest Callbook or with copy of license sent with order.

Call or write now for our complete ATV catalog including downconverters, transceivers, linear amps, and antennas for the 70, 33, & 23cm bands.

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
6 Jenny Lane
Baltimore MD 21208

HF RTTY

The theme of this issue of *73* is HF antennas. HF antennas suggest HF RTTY. That is quite a different animal than VHF RTTY in several ways, so we'll spend some time exploring the lacets peculiar to HF RTTY operation.

To begin with, just where do you find a RTTY station on HF? I spent some time tuning around the ham bands, to see just where the activity was on a typical summer's eve. Here in Baltimore, the traditional "hot spots" of 3620 kHz and 14.080 MHz remain one's best bet to find a RTTY QSO. The lead, at least during the early summer, goes to 20 meters, where one session's monitoring picked up stations from all over the United States, several in Europe, and Israel.

Less channelized than VHF, RTTY operation on the HF bands tends to be a bit more hit-or-miss, usually with CQs and RYs being heard. One great advantage to setting up for HF RTTY is the W1AW RTTY bulletin. Currently being sent daily at 0100Z, 0400Z, and 2200Z; and Monday through Friday at 1500Z: RTTY bulletins are sent on 3.625 MHz, 7.095 MHz, 14.095 MHz, 18.1025 MHz, 21.095 MHz, and 28.095 MHz. The transmissions are in 45.45 baud Baudot, 110 baud ASCII, and 100 baud AMTOR in FEC mode. For the amateur setting up an HF RTTY station, these automated bulletins, sent on time, on frequency, and with a strong signal, often provide just the tool to line up the receiver or converter. The information they provide, frequently the latest FCC ruling or information, is not a bad side benefit, either!

Transmitting RTTY on HF may take several paths, as well. A basic CW transmitter may be frequency-shift keyed with a diode and capacitor placed across the frequency-determining element. This "shift-pot" technique was in widespread use before the advent of frequency-synthesized transmitters. Suitable circuits have been printed in "RTTY Loop" before, and I will be happy to run some of them again, if there's enough interest.

Several transmitters provide an internal RTTY mode, and there's also an external adapter specifically designed for RTTY. If such a device is in your hands, going digital is simply a matter of flipping a switch!

The bulk of "modern" amateurs, however, are injecting a frequency-shifted audio signal into the audio input of their SSB transmitter to obtain FSK. This is fine, as long as the injected waveforms are pure, clean sine waves, and the transmitter has an adequately suppressed carrier and unwanted sideband. More and more, modern transmitters accomplish this task with aplomb.

The simple terminal unit demodulators, often used on AFSK circuits on VHF, are frequently unable to handle the rigors of HF communication. Signals below 30 MHz are plagued by static crashes, fades, and interference rarely heard on an AFSK signal. The TUs, therefore, need to be a cut above the simple one-chip wonder. While plenty of older designs, such as the venerable W2PAT terminal unit, are extant, the striking advances in technology over the last several years would suggest that, if at all possible, you investigate obtaining one of the integrated, multimode controllers. Units by AEA, Kantronics, and others provide incredible versatility, with an ease of operation only dreamed about years ago.

Having covered where to operate, the transmitter, and the demodulator, for all intents and purposes, any receiver good enough for SSB is good enough for RTTY. Now we are left with the display device. Here you have three choices: a mechanical teleprinter, a dedicated RTTY terminal, or a general purpose computer.

Let me say it here: Mechanical teleprinters are wondrous marvels that absolutely mesmerize me when chugging away with their covers removed. They are also noisy, messy, heavy, and require more attention than many children. If you have one and can keep it going, more power to you. My Model 15 and Model 14 tape equipment were relegated to the storeroom, along with the ASR-33, as soon as a quiet computer printer showed up. I don't have the heart to throw them away, and somehow I always feel I will get them running again.

Dedicated RTTY terminals had their heyday about 10 years ago. You don't hear much about them anymore, with general purpose computers gaining so much ground. If you have one, as with a mechanical teleprinter, use it! But, as with the former beasty, I could not see going out today and buying one.

That leaves us with computers as intelligent display devices. I've seen them all, and you can't beat 'em! I can sit, typing this article in my word processor program, and hit a few keys and switch into the terminal program for my demodulator. Using Windows on a PC, or on a Mac (I presume), you could even monitor the traffic in one window, while attending to some other task in another. Ah, the wonders of the modern age!

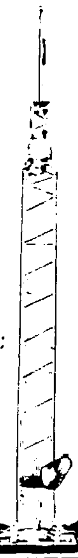
The one thing you won't get from me is a specific recommendation for which computer to buy. There are clear advantages to the inexpensive route, as discussed last month, and there are those who will only be happy with a multi-megaflop wonder. Unless you are devoting the computer to RTTY operation, and RTTY operation only, choose the computer with an eye toward what else it can do for you, not how well it can send data over an RS-232 line. That task is no great feat.

Oh, yes, before I forget—HF antennas. You need one! Go ahead and put up one that will work, one that looks good, one that the wife will tolerate. I could tell you a story about the 80 meter vertical I put up, and how I sold the wife on that one, but I'd have to change too many names to protect the guilty. You get the idea.

I've been enjoying the responses many of you have been offering to the question of what frequency RTTY signals are really on in the HF spectrum. Early returns indicate that there is no consensus as to how to specify a RTTY frequency. That and more are topics for future "RTTY Loop" columns. In the meantime, let me hear from you by mail, at the above address, on CompuServe (ppn 75036,2501), or on Delphi (username MARCWA3AJR). 73

NOW YOU CAN AFFORD THE BEST!

Engineered for the Ham, The Finest in Crank-Up, Free-Standing or Guyed Towers from Tri-Ex. For over 30 years, the INDUSTRY standard-backed up with Defense and Aerospace technology.



MW SERIES
Self-supporting when attached at first section—will hold normal Tri-Band beam: 25', 33', 50', and 65' heights.

W SERIES
Aerodynamic tower designed to hold 9 square feet in a 50 MPH wind. 3 models at 36', 51', and 67' heights.

LM SERIES
"W" brace motorized tower. Holds large antenna loads. Models at 37', 54', and 70' heights.

TM SERIES
Tubular construction for larger antenna loads at 70', 90', and 100' heights. Free standing, with motorized operation.

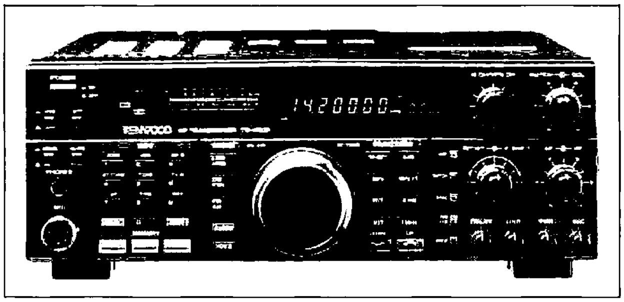
NEW PRODUCTS

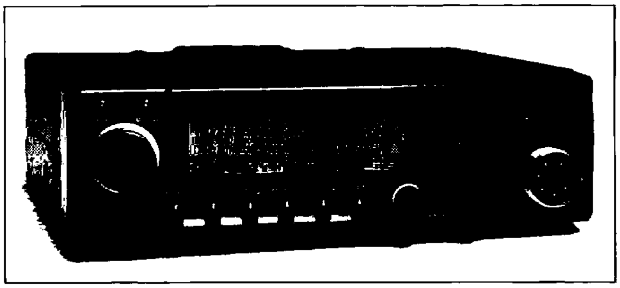
Compiled by Hope Currier



KENWOOD

Kenwood has introduced two new HF transceivers, the TS-450S HF (which replaces the TS-440S) and the TS-690S (replacing the TS-680S). The TS-450S/TS-690S offer many new features, including: direct digital synthesizer; fine tuning function; receiver dynamic range of 108 dB; RF power output control for all modes; the choice of either transceiver with or without the built-in automatic antenna tuner (80–10 meters); and many other features.

The suggested retail price for the TS-450S with the tuner is $1,550; without the tuner, $1,350; for the TS-690S, $1,550. *Kenwood U.S.A. Corporation, 2201 E. Dominguez Street, Long Beach CA 90810. Tel. (213) 639-4200; FAX (213) 604-4487.*



ICOM

ICOM has released the three-pound, 5.5″W x 1.6″H x 6.9″D IC-2410A/H 144 and 440 MHz dual-band transceiver. Its features include simultaneous receive on the same band, two versions of output power, crossband repeat, and 36 memory channels. It is microphone controllable.

Price unannounced at present; for more information, contact *ICOM America, Inc., Corporate Hadquarters, 2380 116th Ave., N.E., P.O. Box C-90029, Bellevue WA 98009-9029. Tel. (206) 454-7619; FAX (206) 454-1509.* Or circle Reader Service No. 201.

SPI-RO MANUFACTURING

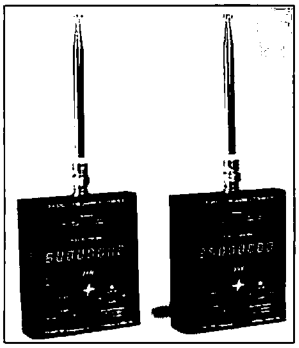
Spi-Ro Manufacturing, Inc., now offers high quality ferrite toroids, rods, shielding beads, and split beads that are much in demand for various applications. Discount prices are offered to amateur radio operators and experimenters. Some kits, concentrating on TVI-RFI prevention, and baluns (both voltage and current types), are also available.

Kits start at $9; toroids begin at $1 each, and ferrite beads at $2.75 a dozen. Ask for a free information packet containing product listings, price sheet, notes on applications, and order form. *Spi-Ro Manufacturing, Inc., P.O. Box 5500, Dept. 105, Lakeland FL 33807-5500. Tel. (813) 646-7925.* Or circle Reader Service No. 209.

J•COM

J•Com is now shipping the HamBase™ database and retrieval software. Owners of IBM/compatible and Macintosh computers can now instantly retrieve the name, address, license class, and year of birth of any licensed U.S. amateur by entering the callsign on their computer. With the click of a key or mouse, the name and address are instantly printed on labels or QSL cards in clear, readable type.

Price for HamBase on 17 1.2M 5¼″ disks, $70; 14 3½″ disks, $80; and 25 800K Macintosh diskettes, $80. For more information, contact *J•Com, P.O. Box 194, Ben Lomond CA 95005. Tel. (408) 335-9120; FAX (408) 335-9121.* Or circle Reader Service No. 221.



STARTEK

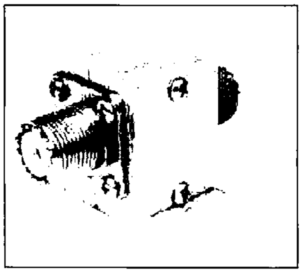
The nine-ounce, pocket-size frequency counter model 3500 from Startek International, Inc., is the smallest Instrument of its type that can measure frequencies from 10 Hz to 3.5 GHz. It has an eight-digit red LED display, a display-hold function, a one-megohm input impedance from 10 Hz to 12 MHz, and a 50 ohm input impedance from 10 MHz to 3.5 GHz. The user can select from three gate times, giving a maximum resolution of 0.1 Hz to 12 MHz, and 10 Hz resolution to 3.5 GHz. Internal NiCd batteries provide 3–5 hours of portable operation. 110 VAC adapter/charger supplied. 12–9 VDC auto adapter optional.

Suggested price, $250. *Startek International, Inc., 398 NE 38th St., Ft. Lauderdale FL 33334. Tel. (305) 561-2211; FAX (305) 561-9133.* Or circle Reader Service No. 203.

SOLARCON

Solarcon Corp. of Holland, Ohio, manufacturer of the complete line of Antron antennas, as well as other antennas for amateur radio, CB, and the cellular and scanner markets, announces that June 1, 1991, it retired the Antron name, which was created solely to market the A-99 base station antenna. From now on, Antron antennas and all of their other products will be marketed under their original company name, Solarcon.

The company is still located at the same address. For more information, contact *Solarcon, P.O. Box 176, Holland OH 43528. Tel. (419) 865-5877; FAX (419) 865-9449.* Or circle Reader Service number 202.



Flange-mount lightning protector.

POLYPHASER

PolyPhaser Corporation has developed a new multi-strike Flange Mount Coaxial Lightning protector which blocks DC, thus preventing harmful surge energy from reaching your equipment. These units are designed from 1.5–1000 MHz bandwidths. They come complete with weather washer, stainless steel hardware, UHF or type N fittings, and can be mounted on ⅛″ thick entrance panels. Price, $53.

Also new from PolyPhaser is a multi-strike IS-RCT Antenna Rotor Protector. With up to 8 conductors, this EMP rated model is designed to protect rotor housing motors and remote control boxes. In a water-resistant aluminum enclosure, solid bronze clamps mount on tower legs. Maximum surge is 2,000 amps per line, for a total of 16 amps.

Price for mount for tower with legs ½″–1⅓″ is $50; for tower with legs 1½″–2¼″ is $53. *PolyPhaser Corporation, 2225 Park Place, P.O. Box 9000, Minden NV 89423-9000. Tel. (702) 782-2511. FAX (702) 782-4476.* Or circle Reader Service No. 217.

MOUSER ELECTRONICS

Mouser Electronics now stocks the Ungar 1200 rechargeable soldering gun powered by NiCd batteries. This cordless gun is suited for hard-to-reach areas and time when power is unavailable. Operating up to 30 minutes per charge (about 250 solder joints), this U.L.-listed unit is equipped with a standard tip. Also available are heavy duty and fine tips.

Price, $50. *Mouser Electronics, 2401 Hwy. 287 North, Mansfield TX 76063. Tel. (800) 992-9943; FAX (817) 483-0931.* Or circle Reader Service No. 212.

GAI SYSTEMS

GAI Systems has a new product directory and buying guide for amateur radio operators. Called *HamStuff*, the directory contains information about more than 1,000 vendors of ham radio products and services, and descriptions of more than 5,000 products. Part I, "Stuff to Do," includes chapters on youth activities, programs for disabled hams, organizations, and publications. Part II, "Stuff to Buy," has product descriptions. Part III, "The HamStuff Index," lists addresses and information on vendors. *HamStuff* is published by Walt Garrett NØMAL. He plans to issue annual revisions to the directory.

HamStuff is available for $19.95 plus $3 shipping and handling. Contact *Walt Garrett at (314) 831-6464/6918. GAI Systems Group, P.O. Box 5832, St. Louis MO 63134.* Or circle Reader Service No. 208.

A/V TECHNOLOGY INTERNATIONAL

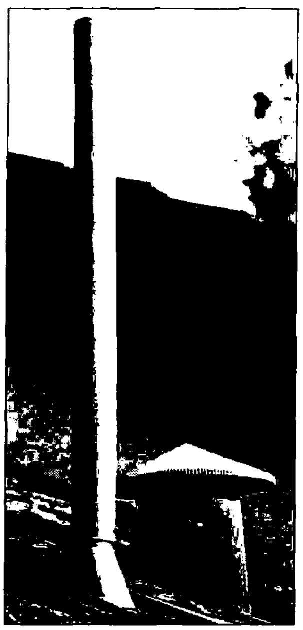
A/V Technology International, Inc., presents ANTENNA ARRAYS SOFTWARE, which computes up to 16 dipole elements. The user can construct driven arrays configured as broadside, end-fire, and maximum radiated signal. You can display the results in a graphic or tabular form. The broadside array is comprised of parallel half-wave dipoles, main radiation lobes perpendicular to the plane of elements. In an end-fire array, main radiation direction is in the plane of the elements, and at right angles to the elements. ANTENNA ARRAYS demonstrates nearly infinite possibilities, even with few elements. Toggle to change display from vertical to horizontal; try rotating to change the polarization. View radiation patterns in both the horizontal and vertical planes.

Price, $60. Specify disk size. Requires IBM/compatible computer with MS-DOS, EGA monitor, and at least 512K RAM. Larger arrays are available as option. *A/V Technology International, Inc., P.O. Box 97, 432 Cherry Street, West Newton MA 02165. Tel. (617) 965-3866; FAX (617) 965-1865.* Or circle Reader Service No. 219.

MFJ

MFJ has just released the MFJ-1268 PC Memory Keyer, a combination of IBM/compatible software and hardware that turns your computer into a powerful memory keyer. It hooks up easily between your computer and radio. You get 100 function key macros that you can easily set to send any messages or characters. You can set a macro to send another macro. Other features include incremental serial numbering, speeds from 5–40 wpm, variable speaker tone (or speaker off), weight adjustment, and instant access to online help.

Price is $50, with MFJ's one-year guarantee. *MFJ Enterprises, Inc., P.O. Box 494, Mississippi State MS 39762. Tel. (601) 323-5869; FAX (601) 323-6551; (800) 647-1800.* Or circle Reader Service No. 211.



THE FORBES GROUP

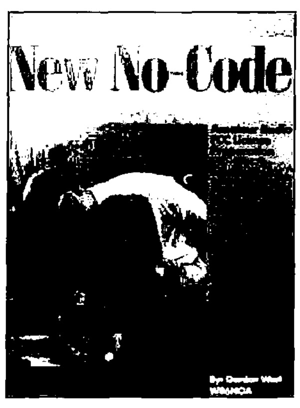
The Forbes Group introduces the 2m Ventenna™, which you can install in less than 10 minutes. You slip it over an existing vent pipe on the roof. Circumventing restrictive ordinances and covenants, it becomes part of the vent. Once installed, the Ventenna is virtually invisible. It covers the entire 2m band, and handles full legal power.

The 2m Ventenna is $40 plus $4 shipping and handling. *The Forbes Group, P.O. Box 445, Rocklin CA 95677.* Or circle Reader Service No. 207.

ELECTROSOFT

Electrosoft has released a new version of the CW-keyboard program and interface kit (described in the January 1991 "New Products") for IBM/compatible MS-DOS computers. The new version adds the capability to receive CW; the original program only transmitted CW. The program/interface receives CW from the receiver speaker and keys the transmitter via one of the computer's serial ports. It copies CW from 2–100 wpm, automatically tracking changes in speed. Received messages are displayed in reverse video in the upper window of the split screen display. Transmitted messages are copied from the bottom window to the top window using regular video display. Received and transmitted messages appear in the order they occur. An "R" in the top status line blinks brightly when the CW tone is present, helping the operator to tune the frequency and volume of the receiver for the best reception.

Program and interface kit, $55; program only, $25; upgrade kit, $30. Specify 5¼" or 3½" disk when ordering. The battery operated interface circuit takes less than an hour to build, and includes all parts plus cables, except for the speaker receiver connector and the transmitter key plus. *Electrosoft, P.O. Box 1462, Loveland CO 80539.* Or circle Reader Service No. 218.



MASTER PUBLISHING, INC.

WB6NOA's *The Technician Class New No-Code* 232-page book published by Master Publishing, Inc., has all the latest Elements 2 and 3A questions. Every question and the four possible answers are listed along with the actual FCC question number. The correct answer is listed right after the four possible answers, with information on why the answer is correct. This way, you don't have to flip back and forth between the back of the book and where you're studying. In addition, Gordon West includes charts, test and theory preparation, information on the Amateur Radio Service, how and where to take the exam, and how to fill out FCC form 610, which is bound inside the back of the book.

Price, $9.95. Look for it at your local Radio Shack or ham dealer! If you can't find it, call *Master Publishing, Inc., 14 Canyon Creek Village MS 31, Richardson TX 75080. Tel. (214) 907-8938; FAX (214) 669-4028.* Or circle Reader Service No. 220.

BelMERIT Corporation

A new product catalog details manufacturer BelMERIT Corporation's line of digital and analog multimeters, function generators, frequency counters, AC/DC power supplies, and accessories. Product specifications are included.

Price of multimeters ranges from $15 to $700. For a free catalog, contact *BelMERIT Corp., 17 Hammond, Suite 403, Irvine CA 92718-1635. Tel. (714) 586-3700; FAX (714) 586-3399.* Or circle Reader Service No. 206.

Number 18 on your Feedback card

BARTER 'N' BUY

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The *73 Flea Market*, Barter 'n' Buy, costs you peanuts (almost)—comes to 35¢ a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to the *Barter 'n' Buy*, Sue Colbert, Forest Road, Hancock NH 03449 *and get set for the phone calls.*

Deadline for the December classifieds is October 1, 1991.

The Great 220 Bandplan Debate

Will anyone win? I think it's rather obvious that the Federal Communications Commission was wrong when it confidently said that the amateur community would find a way to absorb activity previously in the 220–222 MHz spectrum into the 222–225 MHz band. Either that, or it had only localities like Norman, Oklahoma, and Hilo, Hawaii, in its bureaucratic mindset when, in the test of the report and order deleting 220–222 MHz from amateur use, it assured the ham radio community that a transition to a new and smaller 3-MHz-wide band would be without incident. The Commission may know how to write regulations, but it is now painfully obvious that it has no concept of humanity in general and human nature in particular. As a result of this lack of understanding of Homo sapiens' nature, the so-called "easy transition" has become an open war pitting special interest against special interest, and ham against ham.

As I write this column in early June, there are still 50 states comprising this nation, almost that number of concerned frequency coordinators, and at least three times that number of band plans for the reorganization of activity in the 1.25 meter band. Most of the proposals fall into one of two categories. They are either "altruistic" in offering (demanding?) an equal split of the pie for all mode users, or they are selfish in favoring one mode over all other interests. What I see emerging as the 0000 UTC on August 28th "Vacate Day" draws closer is a growing awareness among the minority spectrum users, i.e., the EME enthusiasts, the low-power CW and SSB DXers, the beacon owners, and hams of that ilk, that the majority of their peers will no longer tolerate their existence! That majority calls itself the "FMers."

Why FM Feels It Will Win

Let me begin by saying that I have no ax to grind for or against either side. The time I spend on 1.25 meters is as a user of the N6ENV repeater's autopatch and 223.5 MHz simplex. Sometimes I wander to N6NFQ's fine system, or that of the long-established Valley Good Guys Amateur Radio Club, but that's about it. I actually prefer one-on-one QSOs, all but impossible on repeaters. In years past, I have spent many happy hours in 6 and 2 meter AM and SSB rag-chews and I have chased VHF DX on SSB. Long before most hams realized it was possible to talk from Brooklyn, New York, to Atlantic City, New Jersey, directly on 6 meters, I had racked up a fairly impressive total of 42 states worked and 37 confirmed while running only 7 watts AM, crystal-controlled on 50.4 MHz. In 1969, I also codesigned, built and installed WA2ZWP—the nation's first 15 kHz split-split repeater. (And I thought I had proven that 15 kHz would not work, but nobody listened—hi.) For the past 28 years I have been writing about VHF/UHF, FM and repeater matters for *73 Magazine*, and I have served as a frequency coordinator on two coasts. I will not say that I have "done it all"; far from it, but what I have come to possess as a result of being on both sides of the fence is a far better understanding of certain amateur radio political issues than most.

So let's get right down to the nitty-gritty of what has happened here and in most other urban areas. Simply, places like Southern California have now decreed that 222–225 MHz shall be forevermore an FM band, with a smattering of packet begrudgingly welcome. Other areas, mainly those under the umbrella of the Mid America Coordination Council (MACC), have taken the view that FM will have to vacate a part of the band to make way for the re-allocation of weak signal modes. This will work in MACC territories such as Nebraska, Iowa, Kansas, Missouri and the like, but what is going to happen when the MACC-affiliated Illinois Repeater Association attempts this in Chicago where they have every channel pair filled from 222–225 MHz? I frankly doubt that any repeater will go off the air if a repeater coordinator says to vacate spectrum to make way for the displaced users of 220–222 MHz. And, if a coordinator decides to flex its muscles and try to force systems to vacate, the coordinator will either be ignored, or more likely, be sued.

But the League Will Solve It?

Let's put ourselves into the position of a 220 repeater owner who is told by a frequency coordinator that he has to take his system off the air to make way for another mode. What do you think his reaction will be?

Keep in mind that he already has the frequency. He has the gear. He has the repeater site and most important, he has the backing of his users—the same users who vote for the ARRL director and vice director every two years. So he picks up the phone, dials up his director and says something like: "This is Joe Jones and I own the 222.90 repeater that's been told to get off the air. Mr. Director, you seem to forget that the political power in ham radio lies in only two places: the DXers and contesters with their money, and us repeater folks with our votes. It's not with that handful of crazies who bounce signals off the sun and the moon. Now, do you or don't you want to be re-elected next year?"

If you think this won't happen, and that the ARRL hierarchy won't bend to this pressure, you are very naive. The ARRL Board of Directors is the epitome of the "Old Boy Network." Elected League officials know where their bread is buttered and where the votes to keep them in office come from. Because of this, they instinctively bow to popular political pressure. Look at the turnaround they did on no-code when they realized that code-free licensing would be more popular then unpopular.

What about a quick response by the ARRL for a new approved "Official ARRL 222–225 MHz Band Plan"? If the directors do anything at all—which I tend to doubt—they will pigeonhole the subject by sending it back to the VRAC and VUAC to discuss for the next decade. That way, they make no decision and placate everybody. How many years did it take the ARRL Board of Directors to decide that all three band plans for 2 meters were proper? I think it was 18 years, to be exact. I do not expect the ARRL Board of Directors to do much else but procrastinate, and point to their "local option band plan" escape clause as a way of collectively distancing themselves from this ham community need.

> ***"As we get more no-code Technicians, there will be a call for more and more repeaters for them to operate on."***

Let's Go to the FCC!

I have heard that a few of the EME folks in Texas are thinking of filing a petition with the FCC to request partitioning of the 1.25 meter band to take 222–223 MHz as a narrowband-only emissions subband, and 223–223.5 MHz as a not-to-be-used buffer zone to protect the noise floor of the lower 1 MHz. I suspect that the FCC will get a lot of petitions like this over the next year or so. I also doubt that any will ever see the light of day, for two reasons.

First off, the FCC will ask the ARRL what to do. The ARRL will come back and say, "We don't know." The FCC will then say, "If the ARRL has no idea what to do, and they are the representatives of the wishes of the 'majority' of radio amateurs, how can we, the FCC, know what's best? Maybe we should let it alone and see what happens over the next several years." And, mark my words, they will.

The Law of Supply and Demand

There is something else that the average ham, in his altruistic zeal, tends to overlook: the law of supply and demand and its effect on the hobby. From 1950 to 1968 (approximately), the national (not California) demand was for VHF and UHF gear that was experimentally oriented. In the old days, all of us were "technicians building our own gear," and we were all DXers in the sense that we were all striving to get a better signal to the guy we were talking to. That began to change in the mid-1960s when Ed Clegg W3LOY (Clegg Labs) began putting high quality, made-for-ham-radio transmitters, receivers and transceivers into the hands of amateurs at prices well under what they could home-brew a piece of gear for. Then came Swan with its 250 and 250C: a pair of radios that radically changed the operating habits of those of us on VHF and UHF.

By 1969 or 1970, the rest of the ham world had discovered what California hams had known since the 1950s, FM and repeaters. With the advent of the six-channel Regency HR-2, the six-channel Inoue IC-2F and the three-channel Galaxy unit that never worked, the face of VHF and UHF operating was again changed forever. For all intents and purposes, 2 meters, then 450 followed by 220 and the rest of VHF and low UHF, became "operator" bands with the "experimenter" not just taking a back seat, but literally being phased out.

What does this have to do with the law of supply and demand? Just this: How much SSB and CW gear is made vs. the number of FM transceivers and handhelds? The manufacturers are well aware that the big money lies in two, and only two, markets. These are HF SSB and VHF/UHF FM. True, there have been spurts of weak signal equipment coming to the market, but these units are for the most part nothing but derivatives of existing HF transceiver designs. They come and go quite fleetingly. In fact, the only reason that we are seeing so much new 6 meter gear is because 6 meters has been opened up in most of Europe.

For three decades, the United States accounted for 99% of the potential 6 meter market, and for the past two and one-half decades there has been only a smattering of advanced gear for that band. Most serious 6 meter DXers still prefer the old tube-type Drake TR-6 to anything else. I saw one sell for over $1,500 in the Dayton flea market in 1990. That was three times what the radio sold for in 1968!

The new FM gear for the 222–225 MHz band has either been designed, is in the process of manufacture, or is already on the boat on its way over. Unlike a decade ago, the people who manufacture and import ham gear are not the quiet fellows they were. The amateur radio industry knows that it supplies a special interest product, and to survive, it must sell mass quantities of "product" into mainline use. On HF that means a transceiver for each price range, with 99.9% of the activity being CW and/or SSB.

The market on VHF and UHF is FM. The big three know it. The smaller sup-

pliers also know it, and I think that companies like Radio Shack, Sears, Ward's, Penney's, K-Mart and countless others—others who I believe will come to mass-market ham gear—will also show that they understand this basic marketing strategy. (You should not be all that surprised that I am predicting that a lot of the nation's mass-market marketers will eventually join the ranks of those selling amateur radio equipment. To me, this deduction is as simple as the two words "no-code.")

I think the ham industry—at all levels—is now geared to no-code. Radios are becoming simpler to operate, with much of what's needed to get on the air being preprogrammed into ROM. Plug in an antenna, turn on a radio, key up a repeater, and talk. Not really that different from a TV set, a stereo, or—heaven forbid—a CB radio.

In years past, the manufacturers and importers of the gear we "must" all use refrained from speaking out on volatile subjects for fear of losing business to one another, or to the realm of the home-brewer. But that, too, has all changed. Parts are very hard to come by, and they are getting harder to find every day. This makes the home-brewing of any gear, let alone something like a Kenwood TS-950 or an ICOM IC-781 or a Yaesu FT-1000 (did I leave anyone out?), all but impossible for the average amateur. Therefore, for most of us, this means we buy what's on the market or we do not get on the air.

And Then There Is Politics

Then there is the political impact of no-code for the remainder of this decade. If you are watching the FCC's Tech class licensing figures—and I do—then you see a rather interesting exponential growth pattern developing. Admittedly, it's very early to accurately predict the outcome a decade from now, but if you just project current growth patterns for Techs from the past three months, you find a steady 270% increase each month. If this pattern were to continue for only, say, two years, the code-free licensees would be the dominant license class in the nation. And, with numerical dominance comes political desire.

When the no-code operator becomes the dominant political voice determining the destiny of United States amateur radio policy—and the I believe no-code ham will become that kind of political force—what will the VHF and UHF bands be like? I think that the answer is "utility communications" with little or no room left for exotic experimentation and non-mainline operation.

What Does it All Mean?

I have spent the preceding paragraphs trying to paint what I feel is a realistic national and international picture for you. You don't like it? I have to tell you—neither do I. But hams, myself included, are known to be far more altruistic than realistic. To those of you who would find it far easier to kill the messenger than to accept the reality of the message, I can only offer a bit of pity. You either live in a rather insulated world or have listened to one squelch-crash too many.

When I say that this is only the first of many times—most yet to come—when spectrum will be lost to non-amateur use and we will again have to contract our operations, do not think that my words are insanity. Rather, sit down, read the background information available on the upcoming WARC sessions, and decide for yourself. The cards are stacked heavily against the minority of weak signal enthusiasts, and well in favor of "Joe Ham" who has gone out and spent $400 for a transceiver with "...all those repeaters built in."

I do not see any real future for the weak signal experimenter and exotic mode operator on 222 MHz, or on any other VHF or UHF band, except those in the GHz range—if we still have any of these left after WARC '92 and WARC '93.

I know that forcing the creation of a subband that will be looked on by the masses as the domain of the elite will only bring provocation. Trying to forcibly take more then the masses are willing to give will only bring on an intermode war that the masses, by sheer number, will have to win. Trying to forcibly create a subband by FCC regulation will bring a negative response from the majority of the amateur community, and possibly from the American Radio Relay League. Yet, is it right for the masses to tell the few to go away forever? Is it right for "them" to tell "you" that "you" cannot enjoy your interest because "they" will not give you the room to do so?

Maybe We Need Two Bandplans?

Some have suggested that we have a pair of new 222–225 MHz bandplans. You might say, "one for the crowded city" and another for "the great outdoors." I fear that this approach is not a real solution. Rather, it is a Band-Aid™ that will work only as long as the "great outdoors" remains sparsely populated. No-code will change all that.

As we get more no-code Technicians, there will be a call for more and more repeaters for them to operate on. A lot of these machines will be outside of the traditional urban regions where 2 meters and 440 MHz are already congested. As a result, many will be forced to make their home in the 222–225 MHz band. These new repeaters and their users will erode the "great outdoors" bandplan and urbanize it. The DXer and weak signal experimenter will again be forced off, and feelings will once again be hurt.

To understand what I am saying you have to let go of today. You have to visualize the future and think in numbers of tens of thousands of new hams coming to the VHF and UHF bands in the next several years. The vast majority of them will be demanding telephone-like quality to their communications—be it voice or data. Having multiple bandplans based on current activity is closing one's eyes to the future. Have we not done that enough already? 73

ZD ENGINEERING PRESENTS

★★★★ THE CATV ★★★★

HARDLINE MATCHING TRANSFORMER

The ZD Engineering quarter-wave matching transformer is designed to provide an accurate and broadbanded impedance match between very low loss 75 Ohm CATV hardline and a 50 Ohm load. In addition it provides a reliable and inexpensive method of attaching type N or SO-239 connectors.

Matching transformers are built for the following frequencies.

144 MHz, 222 MHz, 440 MHz, 903 MHz, and 1296 MHz. Units below 200 MHz are built with type N or SO-239 connectors while all others are built with type N only.

Units are built to fit 1/2, 3/4 and 7/8 inch hardline.

Custom built transformers are available for any frequency between 100 MHz and 1.3 GHz as are units built to fit other sizes of hardline. When ordering, please include a 4 inch section of your hardline and specify the design frequency and connector type you need.

Price for 144 MHz units is $29.95 per pair plus $5.00 shipping UPS. 222 MHz, 440 MHz, 903 MHz, and 1296 MHz units are $27.95 per pair plus $5.00 shipping UPS. Ohio Res. add 5.5% sales tax. Custom built prices on request.

Units may be obtained from:

RF Filters for VHF and Above

With all the laser applications now seeded in the last few columns, I want to sit back and see what develops. I plan to continue my pursuit in this part of the spectrum, and I'll be glad to pass on information and applications you want to share. This month, in response to questions, I will cover RF filters and expand on a few applications. The beauty of some of these filters is that they're almost ready to go, right off the shelf. I'll start by describing some of the filters that I've used in past years which still have desirable traits today.

The subject of filters generally comes up when you have a piece of equipment that works, but needs improvement. This was the case with a simple 2 meter FM rig I used back in 1960. The receiver had a 6BQ7 for the front end, and the transmitter was home-brewed with 6AQ5 tubes in the multiplier string. Normally this tube was used for a receiver audio stage, but it worked well at 2 meters mainly because it was available.

The problem I was having was a desensitized receiver, which I traced to several local strong high power commercial transmitters. They were tearing up my receiver; though they were located over 10 MHz away, I could hear them in several spots on the 2 meter band.

You might wonder what this old rig has to do with the modern radio. Well, some of its problems still plague us, especially RF de-sensitization.

Considering their small size, circuits in today's radios work fantastically well, their quality and sensitivity far exceeding that of early radio. But wide-band coverage radios still suffer from adjacent channel interference, or poor selectivity. Selectivity is the radio's ability to operate to full specifications while functioning near an off-frequency transmitter.

Being Selective

What happens in typical de-sensitization is that your receiver goes numb. If you're mountain topping or on Field Day, the view of the city may be great, and the location ought to be great, too, but you get poor performance. You might not even know that your transmitter is getting out, since your receiver is operating poorly. Besides poor performance, the only other clue might be some trash in the unsquelched condition. The problem is quite simple: front end overload or a de-sensitized receiver.

What you usually find at these locations are commercial radio repeaters, or local TV or FM stations, who also thought the location was great. Trying to operate an unmodified radio, like a plastic HT with miniature filter circuits, near their high power transmitters will only cause you grief. About the only radios that don't suffer from this problem are some of the single or multi-channel mobile "taxi" or "police" radios. They have quite a few selective tuned circuits on the receiver input that reject nearby off-frequency signals. Note: these radios have the bandwidth of their front ends reduced from several megahertz (our HTs) to a fraction of that bandwidth.

Just as the commercial radios solved this problem, so can we. The solution is a filter installed on the antenna of our radio to limit or reduce the strength of adjacent RF signals. We design the filter to pass only that portion of the 2 meter band we desire, and to reject other frequency components. Most interfering transmitters operate at 152 MHz and above, making a high *Q* filter very effective in limiting what the receiver input circuit can see.

On field trips I usually use an ICOM IC-02, which is one fine radio unless you're operating near high power TV or FM transmitters. However, connecting a bandpass filter tuned to the frequency of operation restores my IC-02 to full performance.

First, Find the Right Can

The filter I constructed years ago for much the same problem consisted of a beer can cavity filter. It was a steel or tin can, not aluminum. Find one of the larger soup cans that will take solder. To get the proper length of can for your particular application, you can try other cans; tennis ball and fruit juice cans are suitable for frequencies of 2 to 3/4 meters. Other types of cans can be used, depending on length and solder-ability.

The coaxial connectors are mounted on opposite sides of the can, about an inch and a quarter from the grounded end of the filter. The coupling link runs from the connector near the center element, then angles down and is soldered to ground. The spacing on the link is adjusted for insertion loss and impedance matching. The bottom of the filter is covered by a copper or tin plate, or anything that will take solder. The can forms a cavity that is adjusted by a small value variable capacitor mounted at the top of the element.

The capacitor resonates the cavity to frequency. Connect the cavity in line. While listening to an active repeater, vary the capacitor for the highest S-meter reading you can get. This is a hokey method of setting the cavity to frequency, but if you do not have any test equipment it will work quite well.

Do not try to transmit through the filter if it will not pass the receive sensitivity test. When it does pass this test, use only low power until you have thoroughly evaluated the filter. There should be almost no difference in S-meter readings with the filter in or out of the circuit. See Figure 1 for construction details.

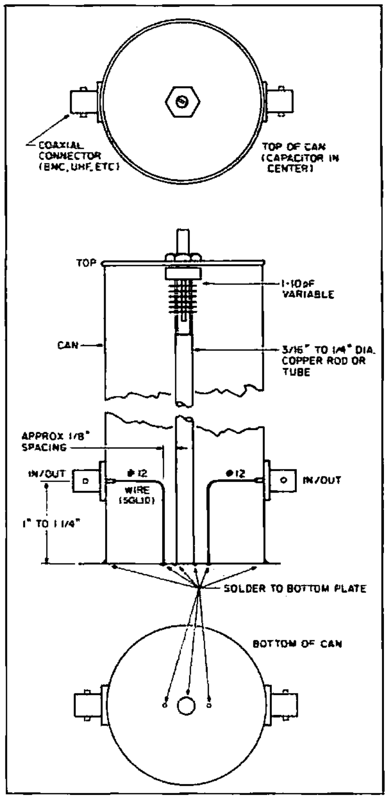

Figure 1. Schematic for the 2 meter, 16-ounce beer can cavity filter.

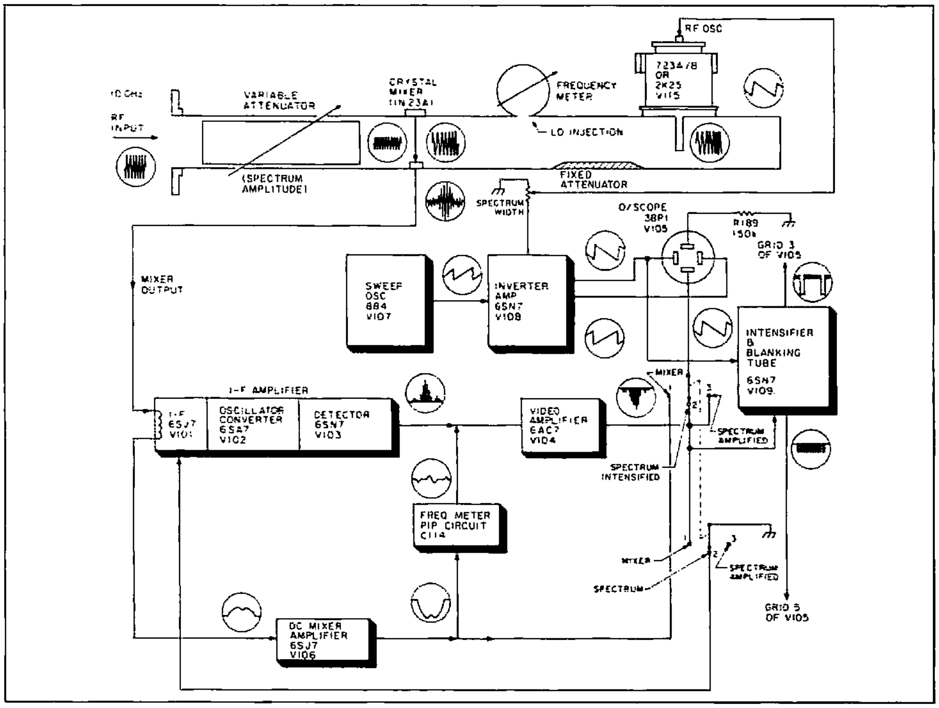

Figure 2. TS-148 surplus spectrum analyzer block diagram. The 10 GHz frequency meter in the photo was removed from this test set.

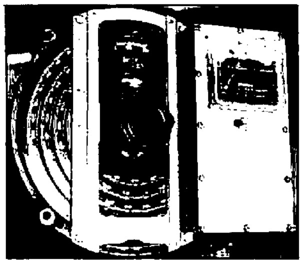

Photo. 10 GHz frequency meter. TS-148 dial removed from test set. The waveguide opening is in the rear.

Heat, Power, and Size

My filter had a very sharp peak at the frequency it was adjusted to, allowing operation on a very narrow band of frequencies. You can use the filter for transmitting, but the power must be low (5 to 10 watts maximum) due to component heating. You can check the filter's performance on transmit with your SWR bridge. It should give a nominal low reading. To obtain minimum SWR, some positioning of the input/output links may be necessary. With the filter in place, adjacent transmitters should not give you further problems.

If you change your frequency of operation, don't forget to change the filter tuning, as it is quite narrow. I usually set mine and use it only on certain hilltops, removing it when I am mobile. This avoids distracting problems that could come up while I'm driving. Normally, a filter is not needed in mobile applications, as the location changes rapidly, especially on the California freeways.

A variation of this simple cavity type filter is the trough line circuit, housed in a rectangular enclosure with one side open. There is nothing wrong with using either type of filter for transmitting, but you must keep the power low. Insertion loss runs about 1/2 dB. Commercial, high power transmitters use the same type of filter concept, but the design incorporates a very large cavity structure nearly 1/4 wavelength long. With a tin can, losses are greater. A small filter can't handle very high currents.

As noted, short filters using variable capacitors should be limited to transmitters of 10 watts or less. A 1/4 wavelength filter for 2 meters is almost 20 inches long, and not very portable. It must be made of heavy and durable material, considering the high RF currents it is subjected to. You probably have a similar filter in your local repeater duplexer to connect the receiver and transmitter to the same antenna and to reject off-frequency signals.

Mailbox Comments

Robert DePaul of Union City, New Jersey, is converting a TS-148 radar test set for use at 10 GHz. This test set is available from many surplus dealers. While it is tube type and somewhat bulky, I used two of them in my first 10 GHz test sets to set up, with my microwave group, 10 GHz transmitters.

The TS-148 operates from 8.5 to 9.8 GHz. This unit is a spectrum analyzer of the old world, about 1950 or '60 vintage. It has an o-scope presentation with variable frequency meter (mechanical) built inside the case. It's about 14 inches square (front panel) and 16 inches deep. Power is from 110 AC mains.

Robert's conversion involves removing the klystron tube and breaking off the klystron's brazed limit screw. But you can also file off the tube's brazed lock nut, which allows you to adjust the screw, compressing the cavity past the factory set limit. This raises the frequency for operation on the 10 GHz band.

To convert the wavemeter for 10 GHz, remove the front cover plate to access the dial. Set the dial to the highest frequency (a 966 dial reading = 9.66 GHz). With the unit face up, partly unscrew the four corner screws holding the dial plate "MC/10." Loosen the top screws more than the bottom screws. Now, carefully raise the top of the dial holder and fudical with the MC/10 dial set to 966; drop two tracks with the MC/10 dial, now set to read 899.5 (8.995 GHz).

This makes the cavity electrically smaller, and resonant on the 10 GHz ham band. Each frequency meter converted in this manner will be different, but close to the reading I obtained on re-calibration on 10 GHz, as follows: 10.280 GHz = 935.6; 10.250 GHz = 933.9; and 10.220 GHz = 932.2. This should guide you on what to expect if you do your calibration in the same manner.

If desired, you can return the meter to its original calibration by raising two tracks. If you want this reversibility, be careful when making the modifications. Before you set the unit on its bottom, tighten the screws to prevent the dial from shifting. See Figure 2 for a block diagram of the TS-148. Next month we will cover the TS-147 companion.

As always, I will be glad to answer questions about microwave or related topics. Please provide an SASE if you wish a personal reply. Best 73's Chuck WB6IGP.

CIRCUITS

Great Ideas From Our Readers

Diode Voltage Doubler

This circuit doubles the voltage output of a transformer and could easily make the difference between your completing a project or leaving it until you can get the proper transformer. Remember that while you are increasing the output voltage, you are reducing the available current output. Do not exceed about 40 percent of the rated current capacity of the transformer.

John R. Somers KC3YB
Crisfield MD

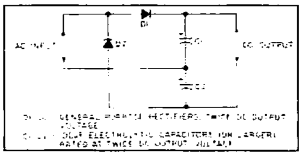

Fig. 1.

Listening to Your Rig While Doing Something Useful

Many times I've wanted to monitor a frequency for a scheduled call, or for a net to start, or to listen for some DX activity, but had chores I should have been doing that would keep me out of hearing range.

One solution was to turn the audio way up. The XYL soon put a stop to that. Another solution might have been a long earphone cord, but that probably wouldn't have been compatible with the hedge clipper.

A simple solution to the problem was provided by coupling an inexpensive FM transmitter module to the receiver audio, and listening on a portable FM receiver.

Circuits for short-range FM transmitters have been published, and several are available commercially. Almost any of these would work, but the easiest approach was to use the FM-1, sold by Ramsey Electronics in kit form. It is quite small, inexpensive, and can easily be packaged with a battery and microphone cartridge and placed next to the speaker or taped to an earphone. However, better sounding audio will result if the earphone jack output is fed through a reversed audio output transformer directly to the module, bypassing the microphone. In this case, a 500–1,000 ohm potentiometer across the unit's input may be needed to supplement the receiver's volume control.

Figure 3 shows a circuit that will accomplish this. Just tune to a quiet spot on the FM broadcast band and adjust the input levels for best fidelity.

I've actually used this gadget with an FM-earphone radio while mowing the lawn. And, I've had the added advantage of being able to QSY to some soothing music when the QRM got too rough.

Marty Kleinfeld K1FHR
Naples FL

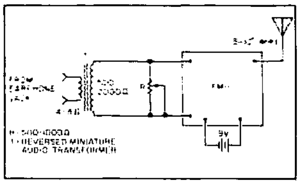

Fig. 3.

Adding a Gain Step Switch to the LM386 AF Amplifier

The LM386 is a very useful audio amplifier in an 8-pin DIP package. Variations of the LM386, identified by suffix numbers −1 to −4, provide up to 0.7 watts of audio to a low impedance speaker or headphones. This chip contains an internal circuit accessible at pins 1 and 8, so the overall gain can be set at 50 to 200 times by an external resistor and/or capacitor.

In some instances it can be desirable to limit overall gain to less than maximum, which corresponds to maximum current drain, especially in battery-operated equipment. A 10k ohm audio taper potentiometer is used normally to control the input level. A single-pole, three-position switch has been added so that the maximum gain can be set as desired between 50 and 200 times.

Figure 2 illustrates a typical AF amplifier using the LM386. Provisions for a speaker and phone jack are included. The speaker is silenced when headphones are plugged in.

The Penguin Islands

There's a new DXCC country. The number of DXCC countries has risen to 323 with the addition of the Penguin Islands to the list, almost a year after the application was submitted to the ARRL. The following ARRL Amateur Radio News Release dated May 31, 1991 summarizes it nicely:

"By unanimous vote (7–0), the ARRL Awards Committee has ACCEPTED the recommendation of the ARRL DX Advisory Committee that the Penguin Islands (ZS1) be added to the ARRL DXCC Countries List. That recommendation was based on Point 3(a) of the Countries List Criteria (separation by another DXCC country).

"The Penguin Islands, administered by South Africa, are situated off the west coast of Africa. Namibia (V5) separates the islands from South Africa (ZS1-6).

"To the best of our knowledge, there have been two creditable operations from these islands: ZS9A/1, DK9KX/ZS1 and DL8CM/ZS1 in July 1990, and ZS9Z/1 in December 1990.

"QSL cards may be submitted for DXCC credit beginning September 1, 1991. Cards submitted before that date will be returned without credit."

The ARRL news release mentions the callsign DK9KX/ZS1, but DK9KX (and other operators) actually signed ZS9AAA/1, not DK9KX/ZS1, during the first operation from the Penguin Islands. The callsign DK9KX/ZS1 is mentioned on the DXpedition QSL card, along with DL8CM/ZS1 and ZS9A/1, but I have found no one who has received a confirmation for a contact with DK9KX/ZS1.

QSL routes for these operations are: ZS9A/1 via OH2BH; ZS9AAA/1 via DK9KX (direct only); ZS9A/1 via ZS9A; and DL8CM/ZS1 via DL8CM.

Jarvis Island

Since before the AH3C/KH5J DXpedition (April 13–22, 1990), the question of separate country status for Jarvis Island has gone unanswered. This possibility is being tested by an application for separate country status submitted this past May by several of the AH3C/KH5J operators.

Eric K3NA wrote a lengthy and well-documented application for separate country status during early 1990, but evidently his document, if it was submitted to the ARRL, has not been acted on. During this past May another attempt at making Jarvis Island a separate country was launched by the AH3C/KH5J operators. Their application, which appears to use most, if not all, of the data compiled by K3NA, is based on Point 3(b) (a part of the Criteria that the DX Advisory Committee is attempting to change) of the DXCC Countries List Criteria: "Where two islands, of the government under Point 1, are totally separated by an intervening DXCC country (also under Point 1), 'each' island counts as a separate DXCC country. . . ."

This application shows that Jarvis Island is separated from Palmyra Island (the nearest U.S. land) by sovereign Kiribati territory. It is well-written and should give the DX Advisory Committee plenty to think about.

Myanmar (Burma)

The Myanmar DXpedition, led by Romeo 3W3RR (1S1RR, YAØRR, etc.), is now scheduled to begin in late August or early September. The callsign has not been made public, to prevent its use by pirates. The callsign will be announced about five days before the DXpedition begins. Romeo has a license that has been accepted by the ARRL. Romeo and company will operate from one of two possible sites: an island off the coast of southern Myanmar, or somewhere within the "Golden Triangle."

3CØ Annobon (Pagalu)

Annobon, or Pagalu, whichever name you wish to use, will be activated in August by the Radioclub Garrotxa and the STC URE Garrotxa. Transportation and licensing have been arranged, but the exact dates in August have not been announced. Contributions for this DXpedition may be sent to Radioclub Garrotxa, P.O. Box 56, Olot, 17800 Gerona, Spain. Thanks "DX News Sheet."

VP8 South Sandwich Island

The South Sandwich Islands DXpedition is a go again! This DXpedition is associated with the group that aborted their DXpedition last December. Eight operators, not yet identified, are scheduled to land on South Thule Island December 6 and be picked up on December 20. The research vessel *Abel J.* will provide transportation. According to the announcement received from KA6V and AA6BB, in order to discourage pirates, the callsign will not be released until the operation actually begins.

KA6V and AA6BB noted in their announcement, "Altho' we have some finances in the account, we do need to call upon your generosity. This new ship will cost only $50,000, which is considerably better than the cost of last year's vessel. . .$100,000. The cost of the vessel is the reason last year's DXpedition was cancelled." Please send contributions to AA6BB.

USSR—Oblast Ø52

Alex UA4HVV, who was active earlier this year as UA3Y/UA4HVV, will operate from oblast Ø52 during the last two weeks of August. He will sign UI7T/UA4HVV from a location called Dinosaur Plateau at 10,000 feet elevation. This location, according to Ed NT2X, has dinosaur footprints recorded in lava. Is this the first recorded hotfoot? QSL via UA4HVV. 73

SPECIAL EVENTS

Ham Doings Around the World

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the January issue, we should receive it by October 31. Provide a clear, concise summary of the essential details about your Special Event. Check /HAMFESTS on our BBS (603-525-4438) for listings that were too late to get into publication.

SPRINGFIELD, IL The Sangamon Valley RC will hold their New Berlin Hamfest from 8 AM-1 PM at the Sangamon County Fairgrounds in New Berlin. VE Exams. Flea Market. Tickets $3. Indoor tables $10. Talk-in: 146.805 - .600. Contact ***SVRC, PO Box 8252, Springfield IL 62791. Don WD9EBK, (217) 789-4519.***

SPECIAL EVENT STATIONS

SEP

VERMONT Throughout the coming year Special Event Stations in Vermont will operate 25 kHz up from the bottom of the Novice and General band, to help celebrate Vermont's 200th Anniversary RTTY/AMTOR/etc. will be in the digital sub-bands. For a special certificate send $1 and a SASE to ***Amateur Radio Bicentennial Project, PO Box 200, Graniteville VT 05654.*** Foreign stations send only SAE and IRC's to cover postage.

SEP 1

SCHAUMBURG, IL The Schaumburg ARC will operate WB9TXO 1500-2100 UTC, from their Demonstration Station at Schaumburg's Annual Septemberfest. Frequencies: 7.291, 14.291, 21.291, 28.391. For special certificate send OSL ,to ***SARC, PO Box 68251, Schaumburg IL 60168-0251.***

SEP 6-8

PUT-IN-BAY, OH Members of the Oliver Hazard Perry Expeditionary Force will operate KB8BN from Perry's Victory and International Peace Memorial, to commemorate the 178th anniversary of the Battle of Lake Erie. The celebration of Perry's victory, and continuing Canadian/American Friendship, will be marked by the return of the restored US Brig Niagara, Commodore Perry's relief Flagship. KB8BN will begin operations at 2100Z. Frequencies: 28.365, 21.365, 14.265, 3.965 MHz. For a commemorative certificate, please send a QSL and large 9X12 SASE to ***Commodore Don Wills, 30372 Bates Rd., Perrysburg OH 43551-3832, USA.***

SEP 9-14

ATLANTIC CITY, NJ Southern Counties ARA will operate K2BR, beginning at 9 AM EST, from the Miss America Pageant in Atlantic City. Atlantic City is located on Absecon Island, which is Iota: NA111. Frequencies: Phone-25 kHz inside lower General class band edge. CW-65 kHz inside lower General class band edge. Novice-28.100/.500 MHz. QSL with #10 SASE via ***SCARA, PO Box 121, Linwood NJ 08221.***

SEP 14

WARSAW, IN The American Red Cross will operate a Special Event Station from 7 AM-4 PM. Frequencies: 15 kHz up from the bottom of General and 28.450± 10 kHz. Send QSL card and SASE to ***KB9AVT Ron Eflinger, Rt. 5, Lendonway Terr., Syracuse IN 46567.***

SEP 14-15

PINE GROVE, CA The Amador County ARC will sponsor Station W6PI as part of the Amador County Gold Country Jubilee from 1700Z-0500Z each day, with SSB on the first half hour and CW the second half hour. Frequencies will be in the lower 25 kHz of the General subbands and the Novice/Technician 10 meter subband. For a commemorative QSL, send your OSL and an SASE to ***ACARC, PO Box 1094, Pine Grove CA 95665.***

SEP 15

SAN JOSE, CA The West Valley ARA will operate Station W6PIY to commemorate the club's 35th Anniversary. W6PIY will be portable from a local park and can be worked on CW-14055, 21120, 28120; or SSB-14250, 21350, 28450, from 1600-2200 UTC. For commemorative certificate, send a SASE to ***W.V.A.R.A., PO Box 6544, San Jose CA 95150-6544.***

SEP 21-22

MONMOUTH COUNTY, NJ The Ocean-Monmouth ARC will operate KC2Q, from 1600Z Sep. 21st-1600Z Sep. 22nd, from the historical Twin Lights Lighthouse. This event commemorates the first commercial use of wireless transmission by Marconi in 1899 from this exact location. Frequencies: 3.970, 7.270, 14.270, 21.370, 28.470. 8½ x 11 certificate available via ***OMARC, PO Box 357, Bradley Beach NJ 07720.***

SEP 27-29

PEA PATCH IS., DE The Tristate IRC will operate KD3XN from historic Civil War, Fort Delaware, on 10, 12, 15, 17 and 20 meters. Operators will be N3EMY, N3IGK, N3ISR, and KD3XN. For QSL please send SASE to operator worked.

YORK, PA The Hilltop Transmitting Assn. will be operating KA3TFI or WF3T in celebration of the 88th year of Harley-Davidson Inc. Operation on CW and SSB, 80 thru 10 meters, from 1400Z-0400Z. Frequencies: Novice 10 meters and General subbands SSB and CW. The stations will operate from the test track behind Harley-Davidson's final assembly plant in York PA. For certificates send QSL and SASE to ***KA3TFI, RD #6 Box 119, Circle Dr., Red Lion PA 17356.***

KINGWOOD, WV Preston County amateur radio operators will operate WM8E from 1400Z Sep. 27th-0200Z Sep. 29th, in celebration of the 50th annual Preston County Buckwheat Festival. Modes will be phone or CW on 40, 20, 15 and 10 meters, approx. 25 kHz up from the bottom of General phone bands or Novice CW bands. For certificate, send QSL and SASE to ***John Wills KE8NO, 104 Swartz Rd., Kingwood WV 26537.***

SEP 28-29

BRANCHVILLE, SC The world's oldest railroad junction will host Station AD4U as the Edisto ARS celebrate their Second annual coverage of the RAYLRODE DAZE FESTIVUL. AD4U will operate 14.285, 21.375, and 28.400 MHz± and area 2m repeaters from 10 AM-10 PM EDST on Sat., and 1PM-6PM EDST Sun. For a distinctive 8½ x 11 certificate, send QSL and SASE to ***AD4U, PO Box 2045, Orangeburg SC 29115-2045.***

UPDATES

Allderdice Students Contacted the Atlantis

In Philip Chien's article, "The Flight of STS-37" in the June 1991 issue of *73*, the list of schools contacting the shuttle *Atlantis* was incomplete.

The students at Reizenstein Middle School in Pittsburgh joined the students at Allderdice High School in Squirrel Hill, Pennsylvania, to use the Allderdice High School ham station. Reizenstein Middle School was mentioned in the article, but Allderdice High School was not.

Operating with the callsign W3BMW belonging to Allderdice teacher Ed Karsin, students from both schools were able to experience the thrill of contacting the shuttle.

We apologize to Ed and the students of Allderdice High School for omitting them from the list of schools.

OMIK Inquiries

See the information on OMIK, submitted by Ocran M. Carr K9RGV, on page 8 in "QRX" of the June 1991 issue. If you would like to know more about OMIK, contact OMIK's secretary: Thomas A. Spight, P.O. Box 805, Racine WI 53403.

QRP Column Correction

In last month's "QRP" column (August 1991), there was an error in the PC board foil pattern and parts placement for the pulse charger circuit. The in and out pins of the optional LM317K device were reversed. Note, however, that the circuit will work if you use the LM317T device instead. Figures 1 and 2 show the correct foil pattern and parts layout.

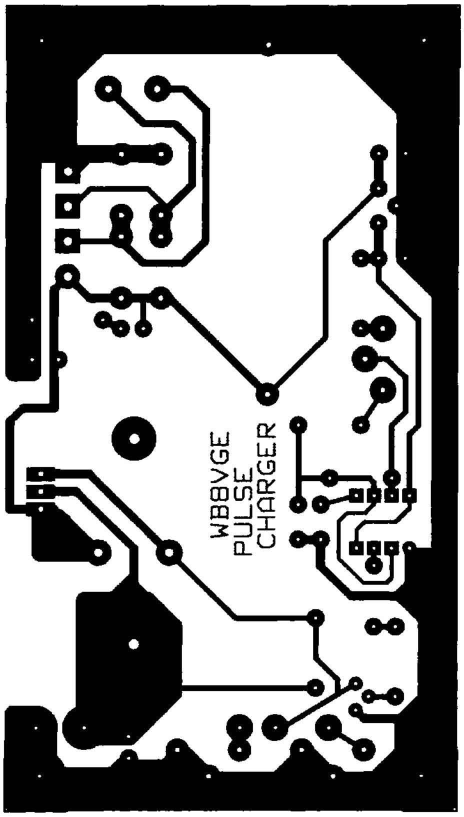

Figure 1. Corrected PC board foil pattern for the pulse charger (August "QRP" column).

VK3 QSL Bureau Alive and Well

In the April 1991 "DX" column, a statement was made that the VK3 incoming QSL Bureau would no longer take cards. Apparently this message was the result of a prank (or worse). According to the Wireless Institute of Australia, the VK3 QSL bureau is alive and well and can accommodate all incoming QSLs destined for the area. 73

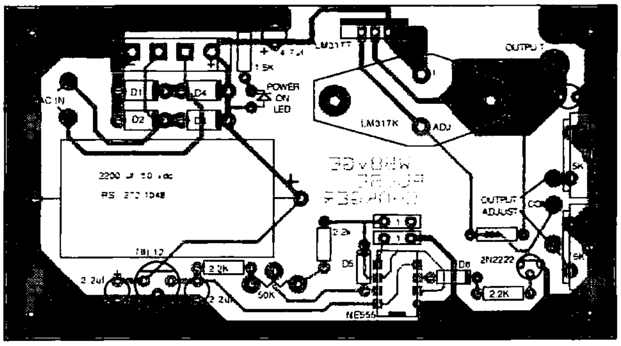

Figure 2. New parts placement for the pulse charger.

Home-Brew Tuner for QRP

Antenna tuners *are easy* to build. But, I've always had the notion you could buy one cheaper than you could build one. Unless you have a very large junk box stocked with wide-spaced variable capacitors and roller inductors, you have to purchase all the parts new. Have you looked up the price of a roller inductor recently? Talk about the national debt!

Even though you can't really beat the roller inductor for getting the precise amount of inductance, they're hard to mount. They also require a logging scale of some sort so that you can re-tune to the same spot if you change bands and come back later.

Running QRP, we have the option of using a rotary switch to select the inductance as *needed*. To a point, RF breakdown of the components is not a factor at QRP power levels; the tapped coil is not as accurate as the roller inductor, but it will work just fine.

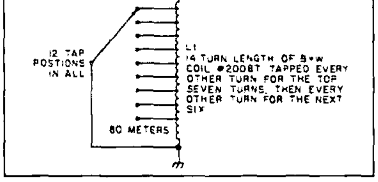
We'll need some type of chassis to house this project. To this day, I don't enjoy pounding holes in metal, let alone bending the stuff into a chassis. Radio Shack once again comes to the rescue with a project box, RS 270-274, for about ten bucks. A good value if you include all the suffering you'll save yourself by buying it. Don't use a plastic box.

The circuit is a classic antenna tuner. Nothing fancy. The fancy work will come in with mounting the parts. Some of the parts may be hard to find. This is not a jump-in-the-car-and-go-get'em project. However, I do have several sources for most of the parts.

Coil and Switch

The hardest part to come up with is the coil. I used B&W 2008T coil stock for the antenna tuner. The coil form is 14 inches long, of which you'll only need about 1-3/4 inches. Here is your chance to stock up the junk box or to make this a club project and use up the whole coil. Those of you who are stout of heart could wind your own, but the B&W is a lot easier!

Next on the shopping list is a switch to select the inductor's windings. Radio Shack sells a 12-position switch like the one we need, but it is a NON-shorting switch. This means that the switch opens before it closes. If you move the inductor switch while you have RF flowing into the tuner, you'll *end up with burnt contacts!*



For QRP, a tapped coil antenna tuner will work fine.

A good switch to use (surplus might be a good place to start looking for this switch) is a Centralab CTS T201. It's an 11-position, make-before-break rotary switch.

Cap Details

Both 360 pF capacitors are standard broadcast type. These are easy to come by. The capacitors MUST be insulated from ground. This includes the capacitors' shafts as well. I used some 1/4-inch thick plastic that I found in the junk box. Two screws hold the capacitor to the plastic, and two more screws hold the plastic/capacitor combination to the chassis. Both capacitors are mounted in this fashion.

You might want to raise the height of the capacitors a bit. Too low and you'll have trouble getting the knobs on, too high and you'll have trouble getting the top of the chassis on. Plan ahead before you get the drill spinning!

Keeping the shaft above ground proved very interesting. I did have some old ceramic couplers lying about in the junk box. They proved invaluable. Lacking these, plastic couplers can be fashioned. Drill out a 1/4-inch hole from round, 3/4-inch thick plastic stock and add self-tapping screws, one for each shaft. The screw will hold the shaft to the coupler. The homemade coupler need be only 1 inch long. If you can't find 3/4-inch round plastic, try a maple dowel. Seal the wood after you're done, to keep moisture out.

You'll also need some 1/4-inch plastic or nylon. A good place to get this is the local hobby store. Steel would be all right, too, but plastic is easier to work with. If you really want to get fancy, a panel bushing would be grand! It gives the entire project a good solid feel when tuning the capacitors. If you have some old pots, these can be disassembled and used for panel bushings. The newer ones won't work. Remember when everyone laughed at you when you brought the dead DX-100 for ten bucks? Well, there has to be half a dozen panel bushing in one of those boat anchors. Who's laughing now?

Solid Connections

The most cumbersome work in building this project was attaching 12 wire jumpers from individual turns on the coil to terminals on the switch. Here's how I did it. Starting at the left end of the coil (the 10 meter end), tap every turn through the 7th turn, and then tap every other turn. Just be sure that the last tap is on the last turn, for 80 meters. Since we're not launching missiles, don't sit up at night worrying about whether you got the tap in exactly the right place or not.

You'll need some rather heavy wire to connect the two capacitors and the switched inductor. I used a small length of #12 house wire after removing the plastic insulation. Soldering should be done with a rather large soldering iron or gun. Use lots of heat to avoid cold solder joints. However, be careful not to overheat the B&W coil, as the plastic ribs will melt.

I used standard SO-239s for antenna connections. Don't cheat and use junk for connectors. Get the good ones with the Teflon™ centers and silver plating. Get the best you can afford. Nothing like trying to save a buck, only to have it come back and bite you.

Even though there are only a handful of connections, be sure they are good and solid. To ensure a good ground, scrape away any paint on the chassis when you mount the SO-239s.

The Least for the Most

There is little to adjust or tune. If you assembled the tuner following the schematic, and insulated the two caps, it should fire right up. Remember, use the least amount of inductance for the best power transfer.

To use the antenna tuner, connect the transceiver and the antenna to their proper connections. You'll need an SWR bridge if your rig does not already have one built in. Set both capacitors at midway, then adjust the inductance control for the highest noise level in the receiver. Apply some RF, and watch the SWR meter. While watching the meter, adjust both capacitors, one at a time.

At some point the SWR will dip down. Add more RF if necessary to ensure an accurate SWR reading. Adjust both capacitors for lowest SWR. If you can't get a match, move the inductor switch up or down one position and try the capacitors again. At some point, you'll find the correct combination and get an SWR of 1:1. If you're not planning on running QRP, remember that the power level is determined by the spacing of the capacitors, the switch, and of course, the coil. With stock parts, don't use more than 200 watts of RF into the *tuner*.

This tuner is for use with antennas fed by coaxial cable. It won't work with random wire or 300 ohm twin-lead. A tuner does not change the SWR of the antenna; it merely provides the correct load for your transmitter. In my case, it allows me to operate SSB on a dipole cut for CW. The SWR is too high in the phone segment of the band on my 20 meter dipole. The tuner is not a magic cure for the wrong antenna!

That's all there is to this project. Most of your time will be spent trying to get the parts. Antenna tuners *are not easy* to build without the correct parts. As I mentioned early on, I have a source of parts for this project, several sources to be exact. (See the list of parts suppliers.) Besides the hamfest and your friend's junk box, try Surplus Sales of Nebraska. They have the capacitors as well as the B&W coil. Also try Radio Kit.

Here's an unexpected source of parts for the tuner: Ten-Tec. Yup! They sell the tapped inductor from their smaller antenna tuner. This part has more taps than specified above for the tuner, but it works great! They also have a good supply of variable capacitors and insulated shaft couplings. You might even get some panel bushings as well.

Enjoy your project. Next month we'll take a close look at portable packet operation, QRP style. ■

Parts Suppliers

Ocean State Electronics
P.O. Box 1458
Westerly RI 02891
Tel. (800) 866–6626 (orders);
(401) 596–3080; Fax: (401) 596–3590

Minimum $5, S&H $4, free catalog. Wide array of RF parts, especially air variables and B&W coils, plus kits for most *QST* projects since 1976. "Non-cataloged items gladly *ordered*." Fast shipping.

Radiokit
P.O.Box 973
169 Jeremy Hill Rd.
Pelham NH 03076
Tel. (603) 635–2235

No minimum ($3 service charge if under $20), many kits, lots of J.W. Miller chokes and coils, B&W coils, RF switches, Millen variable capacitors, lots of parts in general. Send $1 for their catalog.

BCD Electro
P.O. Box 450207
Garland TX 75045-0207
Tel. (214) 343–1770

$1 for 1-year subscription to catalogs; no minimum; $0.95 for under $30, $2.90 shipping. Surplus electronics, pretty random looking assortment.

Surplus Sales of Nebraska
1315 Jones Street
Omaha NE 68102
Tel. (402) 346–4750

New and surplus radio electronics. Wide selection; lots of Collins stuff.

KA7QJY Components
Box 7970
Jackson WY 83001
Tel. (307) 739–1634 evenings

Send a business-size SASE for a current list of parts. RF parts, including vernier drives and air variables. $2.75 shipping, no minimum.

Oak Hills Research
20879 Madison St.
Big Rapids MI 49307
Tel. (616) 796–0920

This is Doug DeMaw's old outfit, now run by Dick Witzke KE8KL. Dick has also purchased Small Parts Center's line of kits and parts. Catalog is $1.00; product line has been greatly expanded with new kits, components, antennas, and many hard-to-find items, including new USA manufactured air variable capacitors, vernier drives, and roller inductors. "Everything" for the diehard home-brewer/QRPer.

Notes from FN42

I am finding it very interesting in this job to see the increased communications coming out of countries that in the past have been closed and controlled. It does my heart good to see these things. Even though I have not had as much time to get on HF as I would like, I hope that others have been taking advantage of these changes.

Solar flares last June made amateur communications difficult, though not impossible. My HF packet traffic back and forth to Ron Gang 4X1MK in Israel seems to make it fine. I put my message on a local packet board here in New Hampshire, and usually within a day it arrives at a packet board near Ron. And most of the DX nets are still prospering.

Before we get to the news from around the world, I would like to make a correction to the July 1991 "Notes from FN42" in which I said that we would find out what Box 88, Moscow, was like thanks to Ron Gang 4X1MK. Ron was just the messenger; Oded Schremer 4X4SO provided the information. Thanks, Oded.—Arnie, N1BAC.

Roundup

Japan From *The JARL News*: From April 8–13, an Amateur Radio Administration Course was held at the Iikura Annex of the Ministry of Posts and Telecommunications, Tokyo, under the combined auspices of the International Telecommunication Union (ITU), the Japanese Ministry of Posts and Telecommunications, and JARL, and also with the cooperation of the International Amateur Radio Union (IARU) and the Telecommunication Advancement Foundation in Japan (TAF).

The main purpose of the international seminar was to contribute to the development of telecommunications in each country through the promotion of orderly development of amateur radio. The last time such a seminar was held in Japan was four and a half years ago. This year, 17 government officials from 17 different countries of the Asian and Pacific Regions participated, all of them representatives of countries where amateur radio operation has only just started or is not sufficiently developed.

Countries participating in the seminar were India, Indonesia, Kiribati, Singapore, Sri Lanka, Solomon Islands, Thailand, China, Tonga, Western Samoa, Nepal, Pakistan, Fiji, Philippines, Bhutan, Vietnam, and Malaysia.

U.S.S.R. From Alex Barinov UA3DCZ: "Within the frames of preparation and carrying out the Orthodox-Christian Cultural Program '600 Years of Saint Sergius's of Radonezh Death' which is conducted in 1991–1992 by the Soviet Cultural Fund, the Saint Sergius of Radonezh Brotherhood will operate from October 5–13, 1991 under the special callsign R3DSR. It will be a radio expedition-marathon devoted to the 650 years of the Saint Trinity-Sergius Monastery that was founded by Sergius of Radonezh, the great churchman and statesman of ancient Russia.

"The radio expedition-marathon is organized by the youthful sports and technical club 'Energy' from Zagorsk, the group of radio amateurs 'Kivach' from Petrozavodsk, the group 'The Union' from Orsk, and the club of collective radio stations from Omsk.

"We will be listening for all amateurs on all bands, both HF and VHF. Radio amateurs and SWLs who establish the most number of contacts and observations on different bands, and radio amateurs younger than 18 years of age, will be awarded special prizes of the Saint Sergius of Radonezh Brotherhood in Zagorsk.

"Send the account with the information about the owner of the radio station not later than November 1, 1991, your QSL for R3DSR, and your suggestions to: Alex Barinov UA3DCZ, Box 4, Zagorsk, 141300, Russia, USSR.

"By establishing radio communications with R3DSR and the radio amateurs of the town of Zagorsk, you can fulfill the requirements for winning the pendant 'Sergius of Radonezh,' the award for 650 Years of the Saint Trinity-Sergius Monastery."

From Igor V. Suprunov UA9MFW: "The West Siberia Collector's Club (WSCC) is for everybody who is collecting anything." Igor UA9MFW is president/founder of the WSCC (and an aircraft plastic model kits fan). Using a home-brew computer and simple printer, Igor and his wife (UA9MLW, a model car collector), and their friends, publish a bi-monthly bulletin, "WSCC Round Table."

You can receive the "WSCC Guide" (for radio amateurs), including membership rules, awards program, and members list with their addresses and collecting interests by sending an SASE with 4 IRCs or 2 green stamps to Igor V. Suprunov, P.O. Box 3360, Omsk, 644020, USSR. Please seal your envelopes carefully. *[Igor sent a copy of the rules for 14 awards given by WSCC. It is too lengthy to include here, but it will be put on the 73BBS (603-525-4438, 300, 1200, or 2400 baud, 8-N-1). The information also lists the callsigns of 40 members of WSCC.—Arnie]*

KENYA

Rod Hallen 5Z4BH
AMEMBASSY Box 55A
APO New York 09675

After four years in Nairobi I have received an assignment to Karachi, Pakistan. I hope to receive a callsign there, but there is no guarantee. Callsigns are hard to acquire. I am to leave here sometime late next year and will be in AP2 country for two years.

The Radio Society of Kenya (RSK) has been working on reciprocal licensing agreements for the past year. The U.S. agreement is in the final stages; agreements for Germany and the U.K. are also in progress. All the details are not in yet, but I will pass them on when they become available.

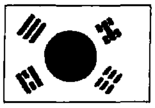
The RSK is planning a Field Day 13–14 July, so look for us. The callsign will be 5Z4RS/A. We are also considering a QSO Party sometime in the fall. One of the purposes of these activities is to promote the Kenyan Award. This attractive award is available to any amateur operator who works five 5Z4 stations who are members of the RSK. The club station, 5Z4RS, counts as two contacts. A certified list of contacts is all that is required, no QSLs.

The award costs $8 or 15 IRCs. The application with certified log data should be sent to the Awards Manager, Radio Society of Kenya, Box 45681, Nairobi, Kenya. Registered mail is suggested but not required.

An interesting sidelight to this award is the fact that most of Kenya's DXers are in regular communications with each other via 2 meter repeater or simplex. Whenever one of us contacts a station that is interested in the award, it is usually possible to get enough members on frequency to fulfill the requirements all at once. By the way, there is usually one or more 5Z4s in contact with John W4FRU on any Tuesday at 1900Z on 21.220 MHz.

The RSK has also recently become very interested in satellite communications. Although we somehow missed the shuttle with its all-ham crew, we have been making up for it by working the Russians. Six of us have made contacts with U2MIR, U5MIR, or RS-11. I talked to Serge U5MIR on June 4, and we were able to have a QSO that lasted about four minutes. On a direct overhead pass he should be good for 10–12 minutes. He says he will be up there until October!! All of this with a 20 watt, 2 meter mobile with a ground plane antenna. *[But OH what a tall tower for that ground plane!—Arnie]*

Many of us have computers and satellite tracking software, so we always know when and where to look. We also have two members with fully functional OSCAR 10/13 stations.



REPUBLIC OF KOREA

Byong-joo Cho HL5AP
PO Box 4, Haeundae
Pusan, 612-600
Korea (South)

The Korean Amateur Radio League's (KARL) three portable stations: HL8A, HL8N, and HL8V, have used special calls during the past CQ Worldwide Contest operating from 78-1, Non Hyun Dong, Kang Nam-Ku, Seoul, Korea. These special callsigns were requested by KARL and the Ministry of Communication issued them for use during the International DX Contest.

Hereafter, KARL shall use D73A, D73DX, and D73CW in every international contest. HL8A = D73A; HL8N = D73DX; and HL8V = D73CW.

There will be three amateur examinations given this year. There are four different class licenses: 1st Class, 2nd Class, 3rd Class CW, and 3rd Class Phone. There will be examinations at eight different locations. The summary as of 15 May is: 2971 examined and 2224 passed for a 75% pass average. *[The most popular appears to be the 3rd Class Phone with 2773/2086.—Arnie]*

SAUDI ARABIA

Charles Martin
PO Box 2830
Dammam 31461
Saudi Arabia

Salaam Aleikum! I have arrived in Saudi Arabia and hope to bo able to report on some of the happenings here and in the surrounding area. If there are any hams in the country or nearby area who have information for inclusion in "73 International," I would appreciate it if you would send it to me. 73.

Say you saw it in 73!

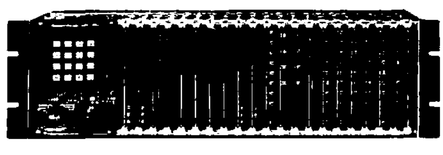
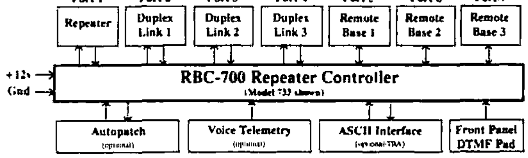
MULTIPLE REPEATER - LINK - REMOTE BASE CONTROLLER

Finally a controller that has solved control and audio interconnect problems between multiple radios. Your radio system can grow to multiple sites and stretch for hundreds of miles - and yet any radio can be fully controlled from any designated input.





The RBC-700 Repeater Controller is designed to support Repeater systems that require multiple radios connected together at a site. The RBC-700 utilizes a true 7 x 7 audio matrix switch which allows several conversations between ports at the same time. In the illustration above the 733 model is supporting a Repeater, 3 Duplexed Links to different sites, and 3 Remote Bases. Using simple commands, a user could tie the Repeater and a Remote Base to one Link, while the other Links are communicating through your site, holding separate conversations. Or, connect all of the ports together - like a big party line !!

Several models are available and are software configurable to support up to 3 Repeaters, 5 Duplexed Links, and 4 Remote Bases. A group or club can start with the basics and expand their controller anytime by simply adding boards and software. Free software upgrades for one year after delivery. Finally, a real controller for the Linked system operator !

Multiple Independent Repeater control	Easy servicing
Up to 5 Duplexed Links	Intergrated Autopatch
Up to 4 different Remotes	Expand at any time
Recorded Natural Speech Telemetry	Programmable Scheduler
Programmable Macros	+ 10v to + 14v Supply
Connect / Disconnect multiple Ports	Standard 5.25" Rack Mount
Internal Receiver Squelch processing	Card-Cage design

Staten Island NY 10313-0006

Men in Blue with Rigs

Several years ago I had the pleasure of meeting Jeff Savasta KB4JKL at the Boxboro Ham Radio Convention in Massachussetts. Jeff is a police officer with the Suffolk County Police Department in Long Island, New York. He was intrigued with the stories I told him about using amateur radio as a motivational tool for youngsters in a classroom. Police personnel have always been very supportive of my program. They are in a position to understand how important it is to interest young adults in worthwhile activities.

I really believe that a major cause of teenagers getting into trouble today is that they don't have the skills necessary to pursue interests that are challenging to them. The police officers in our area know that the children who are involved with the ham radio activities at our school have always been an asset to the community. They participate in many neighborhood events, and are among the first to volunteer when communications are needed.

One of the trips I take my ham radio classes on is to the New York City Police Academy. The communications network they use is very impressive to the children, and helps them understand the importance of clear and succinct messages in times of emergencies. It seemed perfectly natural, therefore, to invite Jeff to speak with the children at my school. I'm always on the lookout for hams with interesting backgrounds to be guest speakers for my classes at Intermediate School 72 in Staten Island. New York. As an instructor, I know how important it is to have not only an interesting person, but also a person who can convey enthusiasm and speak appropriately to the age level of the audience.

The kids were immediately attracted to his uniform and all the "goodies" he wore on his belt. If you invite police officers to visit your classroom, try to persuade them to appear in uniform. Children react well to that. My radio classes were fascinated with his stories about the importance of radio communications in his line of work. He also came prepared with a video that showed how an officer was killed because someone was fooling around and jamming the police frequency. The fact that Jeff is a ham radio operator himself gave special credence to his presentation about how to phone in an emergency. The children felt really special when he told them that the police are especially responsive to calls that come in from hams because they know that hams tend to be responsible and reliable in reporting accidents or other kinds of emergencies that require police intervention.

Jeff's visit to my school was only the beginning of a wonderful ongoing relationship with the children in the radio program. He was soon invited back and made another excellent presentation. The great goodwill a policeman visiting the classroom can generate should not be overlooked. It is extremely important for today's youth to have respect for the fine police officers who risk their lives every day for all of us. Everyone benefited from the contact.

I was especially pleased when Jeff told me he was involved in starting up a police amateur radio club. I hope the following account which he wrote for me will serve to inspire as well as to educate others who are thinking of starting a similar group.

Jeff Savasta KB4JKL Speaks

When I decided to undertake the starting of the Police Amateur Radio Club, I didn't realize what a major task this would be. If this club were being formed by people who work a nine-to-five day, it would probably have been easier. When members work different shifts, it's more difficult to get together.

The Suffolk County Police Department is a major metropolitan police department in a tri-state area. With 2500 sworn personnel and numerous civilian employees, there is a fair population of hams within the structure. Years back, there was an attempt to form an amateur radio club, but it never made it off the organizational level. I wanted to make sure that we would be successful.

At first it was a lonely endeavor. The questions that went through my mind were never-ending. There was a lot of doubt and anxiety about laying the cornerstone of this venture. "Where or how do I start?" I asked myself often. "And when I do, what type of response will I get?"

Then, one day in November 1989, as I walked into my precinct to report for work, I noticed an individual speaking into a microphone in a foreign vehicle next to the detective squad entrance. Curious, I got closer. As I neared the vehicle, I saw a 140–150 MHz VHF antenna on its roof. The individual inside the vehicle was talking on a 2 meter transceiver.

It felt good to see another ham inside the police complex, and it felt even better to realize that he was another cop. That was the first time that I met Detective Doug Lotten N2JHO of the arson squad. I introduced myself, and an immediate bond took place, one which always happens when two hams get within 50 feet of each other. I discussed my idea of a police amateur radio club with him, and he thought it was a great idea. It was comforting to get the perspective of another amateur radio operator who is also a professional peer. We went through the ideas we both had about getting things started.

The first thing I thought we should do was get the idea reviewed and approved by the upper bureaucracy of the department. I composed an internal correspondence in February 1990, and we began the waiting process that so often occurs in large organizations. Finally, in June 1990, after being reviewed also by the department's legal bureau, it was approved by the Police Commissioner.

The perfect way to reach out to our peers was through the departmental newspaper. We wrote an article about the club and got responses. Then we put together a club constitution which took us approximately two weeks to complete. I established a preliminary list of five members and applied to the ARRL for club affiliation. We were approved, and became an affiliated organization in November 1990.

I then decided to put out a makeshift newsletter for the amateurs and nonamateurs Doug and I had talked with in the department. We were surprised at how fast word-of-mouth had spread the club idea. I am a firm believer that hams find other hams, as we are definitely a community within communities, not only in the police structure, but in everyday public life.

In January we had our first meeting. It was plain that because of our different schedules, we wouldn't be able to all meet at the same time. We did have enough members present to carry out club business and hold elections. I was elected president; Doug, vice president; Roy LoBocchiaro KB2KOP, treasurer; and John Isbell KE2TC, secretary. John also took charge of the monthly newsletter and the logo on the letterheads.

We've sparked the interest of the nonamateurs in our department, and are becoming their elmers. We've also received favorable response from the non-police amateur community. Many local clubs have offered their assistance and use of club repeaters. We have been very pleased by this; I don't think many amateurs here in the Northeast are used to seeing the police involved in amateur radio. According to club Secretary John KE2TC, police involvement in amateur radio is more common in other parts of the country, such as the Midwest.

On a personal note, I've been to the class of Carole Perry WB2MGP at I.S. 72 in Staten Island, New York, to speak to the students about amateur radio, and on how police radio operation is similar. Most of the children in the class are intrigued and impressed by the police, as they are at a very impressionable age, and I feel that I should be the best ambassador I can be for amateur radio. Many students will remember their experience, and walk away feeling positive about themselves and amateur radio. I feel that we should all be the best ambassadors of amateur radio that we can be, both in the police and non-police sectors, as amateur radio has given us so much enjoyment and service.

Our club hopes to benefit its members and serve the public, goals all amateur clubs strive to achieve. Though amateur radio operators may come from different walks of life, we are all bound together by a common bond.

If any of you would like to write me or the club with questions and comments, address your letter to: S.P.A.R.C., %Suffolk County Police Dept., 30 Yaphank Ave., Yaphank NY 11980. *[Please also enclose an SASE.—Eds.]*

Never Say Die

Continued from page 4

the regular meetings? License classes? Code classes? By the way, I'm getting piles of letters from new no-coders and virtually every one is enthusiastic about learning the code to get a General ticket. I haven't seen any FCC figures yet showing the increase in hams due to the no-code ticket, but just judging from my mail, it's gotta be encouraging.

I'm hearing from more and more clubs who have been running license classes and graduating new Novices and Techs. My answer to each such letter: Prove it! Send me some pictures to print in *73* and *Radio Fun*.

You want to find some interesting speakers for your club meetings. Maybe you can get a chap like our editor Bill Brown, who's sending ATV cameras up in balloons, to explain this weird hobby . . . and how much fun it is. You must have several packeteers who can put on a show and tell. You may even have some working on higher speed packet.

Once you've worn out your built-in talent, you'll want to look for some nearby ham manufacturers or dealers to invite. Ask them to explain why they are in the ham business, which has got to be one of the most frustrating industries in the world. Just get them talking about some of the hams they've had to deal with and you'll be in stitches. Hams, with probably only two exceptions . . . you and me . . . are crazy as bedbugs.

You know, they just don't have bedbugs like they used to. I've only run into 'em once in my life . . . it was a nice hotel, too. But hoo, what a night I had! It was the Australia Hotel in Melbourne. I couldn't see the little buggers, but they sure could bite. Considering some of the hotels I've visited on my travels, I'm lucky.

You can get ham industry people in to talk if you just ask 'em. Sure, you should buy them a dinner with two or three club officers, but that isn't much of a tab. If they have to come in from a distance you might cover their traveling expenses.

Heck, if I'm in your area I'll be glad to stop by and tell you all how rotten you are. I get to music and audio in-

QSL of the Month To enter your QSL, mail it in an envelope to *73*, WGE Center, Forest Road, Hancock, NH 03449. Attn: QSL of the Month. Winners receive a one-year Subscription (or extension) to *73*. Entries not in envelopes cannot be accepted.

DAIWA

High Quality Power Supplies

Daiwa power supplies use the latest hi-tech circuitry and components providing reliable, regulated DC Power. Short circuit protection protects the power supply in the event of accidental shorting. Crowbar protection protects your rig in the unlikely event of power supply failure. All Daiwa Power Supplies are 120V 50/60 Hz, 220V 50/60 Hz also available.

dustry meetings in Los Angeles, New Orleans, Chicago, Las Vegas, Nashville, Sedalia, San Francisco, Fresno, Cannes and a few other places, so we might be able to coordinate. Save the doughnuts and coffee until after the main speaker so half the club won't be dozing off on stomachs busy converting all those empty calories into fat to hang even further over already-grotesque beer bellies.

I'll be reading your club newsletters to see if any of my advice gets heeded or if you continue to crank out the same old pap every month. I want to start reading about how much fun the last meeting was and what exciting things you have coming up at the next meeting. I want to see the club business handled and reported in the newsletter so it won't make meetings boring. I want to start seeing pictures of your new licensees, your active club members, stories about how your CB search team has found a bunch of young new CBers and gotten them into your club license classes. I want to read about your TVI/interference committee and their successes. I want to read about hidden transmitter hunts. I want to see some SSTV pictures from rare DX. I want to read about any interesting adventures your members have. Have any gone on a DXpedition? Why not? The Atlanta club mounted a great DXpedition to Navassa a few years back. We've got a bunch of fairly rare spots in the Caribbean that are easy to get to and need activation, so what's holding you?

I want to read in your newsletter about your club's team work on cleaning up our bands. Stop griping and do something about it. If you want me to help, send me information on your worst local offenders and some tapes of the messes they're making. Let's expose these cockroaches to the light.

I suppose it's too much to hope for your club to run a member for the League director for your division? You've been re-electing the same old fogies (and crooks, in one case I could mention from bitter and expensive personal experience) every two years. Maybe it's time to make a change? Even the Russians are beginning to change, so why not you?

Is there a local school your club can adopt? Almost any school will be delighted to have your club work with them to interest their kids in amateur radio. They'll love to have your members come in and talk with the kids. I'll bet you can dig up an old rig to help them start their own radio club. Maybe not. I asked for some help in getting some gear for the nearby Crotched Mountain Foundation Rehabilitation Center Radio Club and got nary one response. The Center is a place where handicapped children are helped to cope with their problems. If you won't help handicapped children with an old rig you aren't using any more, we're talking hard-core ambivalence. So let's see you let loose a little and get some gear into your local schools. I want to read about it in your club newsletters.

Sanger Green with Amelia Earhart in 1931.

Better highlight it for me, so I won't miss it.

How many old HTs do you have kicking around? All they need are some new batteries and a pair of crystals for the local repeater and some kid could be in touch with the world from his wheelchair. The kids are eating up the license classes, but they need equipment. The Center is high up on a mountain, so their HTs will work out fine.

The Fogies

It's been a while since I put some ham legends to rest. For instance, there's this legend about how the hams of yore were great builders and technical experts. What a bunch of baloney. Being a certified fogy myself, I was there and I can report what I found.

I grew up as a ham in Brooklyn (NY). I kept a map of Brooklyn with every active ham marked on it. I listened to every ham band and kept tabs. Then I'd put on my roller skates and go visit them. I don't think there was an active ham in the area I didn't visit.

Since there were virtually no commercially-made ham transmitters in those days (the late '30s), everyone had to build their own rig. This was simplified by articles in *Radio*, the main builder's magazine . . . and to a much lesser extent, *QST*. I built almost everything of mine from *Radio*.

But building a rig from an article and understanding what's going on are two different things. In all my travels I found just one ham who'd built his own receiver. And I found one ham who knew how radios worked. Cy. He was kept busy by everyone else, getting their rigs to work for them. Cy's main piece of test equipment was a neon lamp.

Oh, I read the technical articles. I read *QST* and the two handbooks (the best by far was by Jones W6AJF), but I still only had a hazy idea of how radio really worked. I was fortunate, in a way, that WWII came along in late 1941. The downside was that amateur radio got shut down instantly. The bright side was that I chose to go into the Navy (in 1942) and went through their electronics school. It was superb. Not even four years of electronics in college would have given me 10% of what I learned in nine months at the Bliss Electrical School in Tacoma Park (MD) and the Radio Materiel School on Treasure Island.

When I went aboard the Drum (SS-228) in 1943 I knew every aspect of the radar, sonar, and radio equipment and could fix anything.

Being thrown off the air by WWII had one additional benefit. My favorite radio supply house, Lafayette Radio, ran a special on classical music records . . . a close-out when Royale Records went out of business. I loaded up with one of every title. This got me even more solidly into classical music appreciation and hi-fi, standing me in good stead as a speaker manufacturer in the '50s and as the editor of a music magazine now.

Well, I've been over all that many times, so I won't elaborate. My point is that the hams of 60 years ago were not much different from those of today. They didn't know much more about the rigs they were using. They had only an inkling as to what was in their receivers. They did as foolish antenna experiments as we see today.

Once I got into ham publishing I found that 99% of the hams are ragchewers. It's the other 1% who are the technicians and the pioneers. It's this little group of fanatics that has done the inventing and paid the tab for the rest of us. As a ham publisher and editor for 40 years, I've had the privilege of knowing most of these movers.

So don't let old-timers sell you any bill of goods about the "real" hams of yore. They were no more real than those we have today. Also, if you find yourself getting upset over the idiots on 14.313, just do a little homework in the *QST*s of the late '20s and early '30s and read "The Old Man" (Hiram Percy maxim W1AW) and his endless tirades about rotten QRM. Nothing has changed. The hobby is just as lousy . . . and fantastic . . . as it's always been.

Amelia? Again?

Will someone please tell people to stop trying to find Amelia Earhart's plane? A few weeks ago they replayed the "Unsolved Mysteries" TV program about her and now I read there's a hunt on to find her plane. Sigh. Yes, I know the Navy hates to admit Amelia was on a mission for the Navy when she was lost. And the Japanese hate even more to admit that they executed her as a spy.

If you'll read Fred Goerner's book, *The Search for Amelia Earhart* (Dell #7689, 1967), you'll get the true story. It took Fred several years of hard work to find out what I serendipitously knew. I've read several books about her disappearance, but none, except Fred's, came even close to what actually happened.

So how come ol' Doc Green knows so much about this? Waaal, first of all my father was a pioneer in the airline business. He started out as an Army pilot in 1921, went on to barnstorm, designed and built the Philadelphia airport, and then became passenger manager for Luddington Airlines—one of the first commercial carriers, which was owned by Tommy Luddington and Amelia Earhart. In fact, the airline even used her personal Lockheed Vega when they needed it. She kept her plane at my dad's airport, so I knew it well. This was also why I happened to be in the right place at the right time to be a passenger on the first commercial airline flight in America. I remember getting up in grade school assembly and telling the whole school about it.

Amelia and my dad were good friends and occasionally flew together around 1930. I have pictures of them together.

My father left Luddington to start a new airline between New York and Boston. It would use flying boats so it could operate directly from downtown New York to downtown Boston, thus avoiding the trip to the airports. The main investors were other airlines, which wanted to handle Boston-bound travelers.

In early 1937 Bob Wemple, a long-time friend of dad's, told us about the work he was doing on Amelia's plane. He explained that she was going on a mission for the Navy. Her goal would be to overfly the highly secret Japanese naval base at Truk and take aerial pictures so the Navy could see what was going on. The whole reason for her flight around the world was to get this badly-needed intelligence.

Bob had installed a much more powerful engine and extra wing tanks so Amelia, with Fred Noonan as her navigator, would be able to make the flight from Lae, New Guinea, over Truk, and on to Howland Island in the same time as she normally would have made it direct to Howland. The higher speed would also enable her to outrun any Japanese fighters they might send up. The problem was she missed Howland.

Now cut from 1937 to 1944. I'm at a submarine rest camp in the Marshall Islands for a few days while the Drum was being refitted by the submarine tender Bushnell. In between endless games of Monopoly, some legendary poker games, loafing on some of the most beautiful beaches in the world, and skin diving in the fantastic lagoon, we managed to talk with some natives who had a fascinating story, about a plane crashing seven years previously, the woman (uninjured) and man (injured) who survived. . .the Japanese taking them and their plane to Saipan. Hmmm, so that's what happened to Amelia!

A few months later, when we stopped off at Saipan on our way to Guam for another refit, the natives confirmed that Amelia and Fred had been there. Fred had died and Amelia was executed. When the Americans arrived they exhumed the bodies and burned their plane.

Since I'd heard all about this, it never crossed my mind that there was any big mystery about what had happened to Amelia and Fred. When Goerner's book was published in 1967, I wrote to congratulate him on uncovering the story. I was surprised that he had so much trouble finding out what happened, but with both our Navy and the Japanese doing their best to cover up everything, his story was more about his adventures in fighting the cover-up than what happened to Amelia and Fred.

I remember Bob Wemple well. He visited us on and off for about ten years. He was a short sandy-haired chap with a serious limp and the damnedest waxed mustache I'd ever seen. He was a crack mechanic. He married Miss Philadelphia while flying over that city around 1930.

When the "Unsolved Mysteries" segment about Amelia was aired last year I wrote and explained what really happened. Their report came close, but they had her crashing on Saipan in the Mariannas, instead of the Marshall Islands. They interviewed a native woman who watched the Japanese bury Amelia.

I got a thank-you from "Unsolved Mysteries," but then they repeated the segment again this year with no additions. If I'd been the producer I'd have updated it. Of course, then it might not qualify as "Unsolved." Maybe I should wait for a new series on "Solved Mysteries." Oh well, at least it gives me (or you) something to talk about on the air. . .if anyone ever asks for more than a signal report. No one has yet. But heck, I've only been hamming for 53 years so far. I must learn to be more patient.

"Our gear is going to get more compact, more complex, and cheaper. And that has implications far beyond amateur radio, so we're going to see increased pressures to use our bands for business and personal communications."

Selling IBM Short?

Golly, if you'd only known that IBM's stock was going to plummet, you could have made a killing! How could anyone guess? Well, one way is by reading my editorials.

The cover story on a recent *Fortune* was on the bad news with this bluest of blue-chips, Big Blue. Funny thing about the long article (10 pages). . . no one, including the author and IBM management, apparently understands the fundamental reasons why IBM is sinking. The article, like those I've seen in the *WSJ* and other financial publications, dwells entirely on the symptoms. . .the immediate problems IBM's basic weakness has caused.

Why did I predict about seven years ago that IBM, DEC, Data General, Prime, and Wang were doomed? It doesn't take an astrophysicist to see where technology is headed. And once you understand that you can see why the handwriting is on the wall for the big computer companies.

The minicomputer was the first step. The mainframe computer companies sneered when DEC, Data General, Wang, and others started selling minicomputers. Toys. Well, they were selling computer power at about 10% of a mainframe's cost. Honeywell, G.E., and others ignored the minis and are history. IBM, with around 80% of the mainframe market, got hurt, but learned from the experience and eventually started making minis too.

Their big problem with minis was that they had to sell 10 times as many to make the same money. And they let a few competitors like DEC get too big before they figured out what was happening.

Then along came the microcomputer, selling the same (and higher) power at 10% the cost of the minicomputers. Toys! I had lunch with An Wang and tried to get him to understand what was going to happen. His blindness to micros was unchangeable, even though it was this same blindness by the big iron makers which he had exploited.

I tried to convince De Castro, the president of Data General. He got mad. I talked with the president and top management of Centronics, the largest maker of printers in the world. No soap. They're making pancake turners in the Centronics factory now.

IBM held back getting into micros until the government suit against them for their near monopolization of the mainframe computer business was settled. Then they jumped in. Alas, even if they'd been able to control 80% of the micro market (they've got about 14%), they were still doomed as a company.

When micros appeared it was obvious that super-micros would be along. Now we're looking at micros with the power of mainframes, but at 1/100th the cost. Let's say that IBM gets into the super-micro business. With 80% of the market already in hand, how can they sell a hundred times as many super-micros to maintain their same revenues? Oh, a few more big companies will buy them, but not a hundred times as many.

Worse, technology is inevitably heading toward even faster and less expensive computers which will cost a tenth what the super-micros will cost. Just as the Radio Shack Model 100 laptop, which was introduced eight years ago, had more computing power than the largest computers in the world a few years earlier, we're looking at Cray Computer speeds and throughput for a few thousand dollars, not tens of millions.

And even worse, as the cost of computing and memory come down, smaller, faster-reacting firms can run circles around government-sized behemoths. With all due respect, while there may be some fairly bright people in top management (I say there may be. . .I haven't any personal experience to confirm this), the quality of people at lower levels is often heartbreaking. Thus, entrepreneurs can run the big companies ragged with more innovative products and lower prices.

The microcomputer industry grew quickly, feeding on the complacency of the minicomputer firms. Indeed, it grew at a fairly steady rate of 235% per year for its first eight years. Not bad, eh? When all that started I recommended getting into the business.

By 1981 Radio Shack had 40% of the micro market, Apple had 40%, and around 300 other smaller firms shared 20%. Then IBM came in, with an old buddy of mine, Chaz Cone W4GKF, calling many of the shots. They did well for a while, but eventually faster-moving entrepreneurs took more and more market share away from them.

IBM is firing thousands of people, but you seldom can save a business by economizing. More often you have to sell your way out of trouble. . .and there isn't enough of a market in the whole world to support IBM at its present size once their big iron has been made obsolete.

Hmph, I hear you grumble, so what's all this horn-tooting by Doc Green got to do with amateur radio? Plenty. It may have escaped you that today's transceivers are packed with computer chips. Synthesizers, memories, packet, RTTY, and so on are all made possible by these chips. The faster and more complex they get, the lower the cost of advanced communications technology. What I'm saying, translated into ham language, is that you ain't seen nothin' yet! Our gear is going to get more compact, more complex, and cheaper. And that has implications far beyond amateur radio, so we're going to see increased pressures to use our bands for business and personal communications.

Oh, I get pathetic letters from old-timers who are in sticker shock over the cost of today's radio gear. Apparently they haven't noticed what 40 years of inflation has done to prices. Today's radio gear is an incredible bargain compared to the prehistoric stuff we used to buy for 10 times the price (and more) a few years ago.

As ICs get more and more crammed into them, we're going to be able to do things not even imagined today . . .and in just a few years. Super-micros and megabyte memory chips are going to change things. Packet, RTTY, high speed CW, SSB, and so on, all in an HT, complete with a small keyboard? Yup. It's coming. The question is, now that you know, are you going to take advantage of this and ride the crest of the wave or are you going to flounder around. . .or, like IBM, get crushed as the wave sweeps over? 73

Photo B. "So it's this way, right?" Igor Krivosheev UW0CZ learns how to use a SuperDF before the FRG-91 foxhunt. Igor teaches radio and orienteering to pre-teens in Khabarovsk.

Foxhunters Invade Oregon

"As you are reading this, 10 Soviets are taking over Portland's Forest Park!" Everyone laughed as Kevin Hunt WA7VTD read these words from the podium at the opening ceremonies of the 1991 Friendship Radio Games (FRG-91).

The sentence came from a news release he had sent to local radio and TV stations to ensure that the Games would not be overlooked by the media. It was a tough sell, because on that day 99.9 percent of Portland sports fans cared only about seeing their beloved Trailblazers beat the Los Angeles Lakers in the NBA playoff series.

But roundball players aren't the only trailblazers in Portland. The hams of that area are pioneers at fostering international goodwill through their hobby. Two years ago, several of them went to Khabarovsk, USSR, for the first Sister Cities Radiosport Games (see the June 1991 "Homing In").

This year is Portland's turn to put on the Olympics of ham radio, and they pulled it off with style. FRG-91 included the first sanctioned international radio direction finding (RDF) competition on U.S. soil.

World-class T-hunters from Southern California, New Mexico, and Washington were invited. They faced a team of championship foxhunters from Japan, and two teams from the Soviet Union. WA6OPS and I were there to serve on the judging team and to cover the games for *73 Amateur Radio Today*

Radiosporting Goods

There are many obstacles to face in putting on an international "foxhunt," as these RDF competitions are called. One tricky chore is selecting and providing RDF gear. To ensure fairness, all competitors should use the same type of equipment. All sets should give uniform performance.

On-foot competitive RDF methods for 2 meters vary greatly from country to country. At home, the Soviets use simple tuned-radio-frequency (TRF) receivers and 3-element yagis. Even if they could have brought these simple receivers with them, the sets lack enough selectivity to perform properly in the crowded band conditions of a typical U.S. city.

In Japan, commercial foxhunt receiver/antenna units are popular. These gadgets feature a synthesized receiver built into the boom of a 2-element phased array (see Photo A). Electronic attenuation and audible strength indication are included. The Japanese 2 meter band is only 144–146 MHz, so their fox-trackers won't work on the popular USA foxhunt frequencies above 146 MHz without modification.

One tricky chore is selecting and providing RDF gear. To ensure fairness, all competitors should use the same type of equipment.

There is no "standard" RDF set for North American foxhunters. The L-Per by L-Tronics is popular with search/rescue folks who hunt aircraft ELTs, but its 4-channel, crystal-controlled receiver limits its usefulness on 2 meters. Dual-antenna time-difference-of-arrival (TDOA) sets are often seen because they work with stock hand-held FM transceivers. (See "Homing In" for September and November 1989.) However, they lack any indication of signal strength to help gauge distance to the fox.

After much discussion, the FARS foxhunt committee decided that all competitors would use SuperDFs. These dual-antenna TDOA sets are manufactured by BMG Engineering of Temple City, California. Owner Russ Andrews K6BMG provided 16 antenna sets and DF display units (Photo B) in kit form to FARS a few weeks before the date of the competition. One of the "big three" ham manufacturers provided pocket-sized hand-helds for use with the SuperDFs.

Building 16 RDF sets in a short time—what a task! But Portland's hams were up to it. When I arrived the night before the FRG-91 foxhunt "dry run," a houseful of them were tweaking up the SuperDFs and bolting on the cases, in between glances at the Blazers on TV.

On the morning of 29 May, all hands gathered in giant Forest Park to test the fox transmitters and RDF sets. It was the competitors' first and only chance to learn how to use the gear before the official competition the following day. It rained, of course.

Despite the bad weather, everyone was excited and eager to seek out the five fraction-watt transmitters that had been scattered on the 200-acre course by Dick Fredrickson WA0DIM and Mike Holgate N7OKJ

The rain didn't hurt the transmitters, RDF sets or receivers. But Murphy had a more serious problem in store.

Killer Cross-Mod

All the fox transmitters' MCW signals were loud and clear through the SuperDF dual antennas with the DF sets powered down. But the fox tones immediately disappeared into the noise when the SuperDF control units were turned on, starting the electronic switching of the dual whips.

Some loss of sensitivity due to commutation of antennas is normal in a TDOA RDF set. But this time it was worse than anyone had ever seen before. The miniature hand-helds were useless.

Full-sized hand-helds with wideband front ends worked better. Older sets with narrow RF stages were best. My old Tempo S1 worked fine!

There are three tall towers near Forest Park with VHF communications, broadcasting, and paging antennas. The presence of strong RF fields causes cross-modulation products to be generated when antennas are switched at an audio rate, as is done in a TDOA RDF set

David Cassidy N1GPH

Colin's Visit

My six-year-old nephew, Colin, came to visit a few weeks ago. He and his mom came up to "the country" from "the big city," for a little fresh air.

We took him to the town fair, which just happened to fall on that weekend. We pointed out all kinds of neat things he doesn't get to see in the city: the deer on the side of the road at dusk, the ground hogs that have a perpetual fascination with our back yard, and the lightning bugs that fill up the yard on a summer evening and mimic the starry sky that glows down from above.

On Sunday morning, Colin reminded me that I had promised to show him my radios. His mom had told me that he was very excited to hear and talk to people from other countries. He and I trotted off to my shack, powered up and sat down behind the HF rig. The concentration on this little guy's face was amazing. He knew that he was entering Uncle David's special room, and he was making sure he was on his best behavior so that I would invite him back.

As we scanned the bands, looking for foreign sounding voices, it soon became apparent that we were experiencing one of those solar flare band wipe-outs that are common in the summer. 10 meters... dead. 15...ditto. I tuned up and down 20 meters, figuring that the DX chasers wouldn't let me down. They did. 40 meters at least offered some signals coming through, but the farthest we could hear was Pennsylvania—not exactly the geographic tour my nephew was hoping for.

So...there I was...sitting next to a six-year-old with the chance to instill in him a love of radio and the darned ionosphere was ruining everything. I could see Colin's interest beginning to wane. Then he asked me "What's that?" and pointed to the code key, which in my shack is usually pushed to the back of the desk and covered with a pretty good accumulation of dust. I explained to him about Morse code, turned the antenna switch to the dummy load and started sending. I sent C-O-L-I-N and told him that was his name in code. Colin's face lit up!

I wrote the dots and dashes under the letters on a piece of paper and explained how to say "dah-dit" instead of "dot-dash." When I asked him if he would like to try it he almost ripped the key out of the rig. His six-year-old fingers took a few minutes to get the hang of it, but after two or three tries he was sending fairly copyable code.

Colin's mom was called immediately to the shack, to witness Colin's newfound skill. He sent his name. Then he sent "hi mom." Mom was suitably impressed. We spent the rest of the morning figuring out short words and simple sentences. The rhythm of "CQ" was a little difficult, but he seemed fascinated by it and eventually mastered it.

After a while, we tried an actual contact. I called a quick "CQ" in the Novice portion of 40 meters and was answered by a weak signal in Virginia. Colin stared at my hand as the sound coming out of the speaker was instantly transferred to letters on the yellow pad. Every time he heard one of the letters he recognized, he shouted it out—"I! S! C! H!" He had a lot of questions about some of the funny looking "words" like QTH, RST, ES, OM, etc. I missed some stuff being sent because I wanted to explain as he asked the question. So what! It was your standard "name, QTH, RST" QSO, and everything was sent twice, so I didn't miss all that much. The signal faded and I caught a final "73" before it disappeared altogether. Colin and I sat at my operating desk and went over the text. He liked the idea of having so many "code" words like QSL and RST.

I let him send some more into the dummy load and taught him a few more letters.

> ***"I sent C-O-L-I-N and told him that was his name in code. Colin's face lit up!"***

When it was time to go, he grabbed the piece of paper that had the dots and dashes on it and took it with him.

Colin did me a great favor. He reminded me that Morse code—with the prejudice and pressure removed—can still be an exciting way to turn on a young mind to amateur radio. I had forgotten that. Anyone who is afraid that the code will eventually pass away only has to look at the face of a six-year-old as he learns how to say his name in this "foreign" language.

A six-year-old's attention span can often be measured in minutes, or at best, hours. Sometimes a task or subject will be so interesting that it is maintained over several days. until it is replaced by something else equally new and fascinating. Without reenforcement every few days, I figured Colin would find something else to occupy his inquisitive mind and active imagination. Sure, when he got home he showed his dad how to send a few words in Morse code (or, as he calls it, Morris code), but I knew he'd soon be off to other interests.

Colin's visit was several weeks ago. Today I received a birthday card from him, his mom, and dad. On the left-hand side of the card, in the steadiest hand a six-year-old can muster, was written,

"·—·· ——— ···— ·
—·—· ——— ·—·· ·· —·"

Thank you, Colin.

Payson AZ 85541

Some of our readers have expressed an appreciation for this column, and N2FZ has told me how helpful it is to him... in fact, he clips it out each month and posts it in the shack for reference. I'd like to hear from you readers who enjoy the column, and especially those of you who have comments, pro and con, about what you like and don't like, and how you think it can be improved. Also, I'd like for you to rate it for accuracy—a batting average, if you will. We all like to know how we're doing once in a while.

One last item before we go to this month's forecast: Please gat a copy of the March 1990 *Smithsonian* magazine and refer to the article, "Do Solar Fireworks Bring Stormy Weather?" on page 32. Author Stephen P. Moran gives us a look at the sun and its behavior, and I find the article one of the best I have read on the sun and its influence on radio communications and other aspects of our environment. The photographs and charts alone are worth looking at, while the text is fascinating

Similar But Not the Same

Conditions for September, October, and November will be similar to conditions last March, April, and May. Spring and fall equinoxes exhibit the same number of hours of daylight and darkness, and as the days progress past the equinox, HF communications deteriorate slightly on the higher frequency bands and improve slightly on the lower frequency bands.

For September, you may look for POOR conditions between the 1st and 3rd, and again between the 20th and 22nd, and finally between the 27th and 29th. "Poor" means that DX paths through the auroral zones are difficult due to active minor (or even major) storm levels in earth's magnetic field. "Fair" means some paths are open while others may be closed, and "Good" means that worldwide DX is probable on those days of the month so marked in the chart.

It is always desirable to check WWV broadcasts at 18 minutes past any hour for their "Solar and Terrestrial Indices" numbers. You want high solar flux (above 180), low Boulder A index (below 10), and low Boulder K index (2 or below) for best propagation conditions via the ionosphere to either short- or long-skip locations.

In September, static levels will decline as Northern Hemisphere thunderstorms subside, and DX on the 40, 80, and 160 meter bands will improve dramatically as the winter months approach. However, the shorter daylight hours mean that the HF bands at 20 meters and above will close earlier, at dark or slightly thereafter, with the 10 and 12 meter bands dropping out first, followed by the 15, 17, and 20 meter bands. Good hunting!

Continued from page 91

These cross-mod products are mostly out-of-band, so they are rejected by narrow receiver front ends. But the latest generation of tiny hand-helds leave no room for selective input circuitry. Furthermore, today's HTs are deliberately designed, as a feature, to be wideband. (Don't you like being able to eavesdrop from 130 to 174 MHz with yours?)

FARS organizers spent the remainder of Wednesday rounding up older narrowband hand-helds for the competitors, and checking them out. A few of the SuperDFs didn't work properly even on narrowband receivers, so John White K7RUN hosted a troubleshooting party at his home that night.

Mike McCarter KA7NOO, Gene Shulgin UZ3AU (see Photo C), and others helped me check over each SuperDF control unit and antenna set, and repair them as necessary. Soldering irons were flying as we hurried to correct reversed diodes, loose BNC connectors, and wrong-value capacitors. By 2 a.m., all units were repaired and tested, and it was time to get some sleep.

Big Day for USA

Except for some old batteries on the borrowed hand-helds, the RDF gear worked fine during the May 30 foxhunt. The five-transmitter course was about two miles in total length. Contestants were allowed a maximum of three hours to find the foxes, in order. Except for a five-minute rainshower, the weather was fine.

Experience with switched antenna RDF methods paid off for the USA. Every US entrant was able to find all five transmitters. Kevin Kelly N6QAB took the gold back to Albuquerque as fastest individual foxhunter. He completed the course in one hour and fourteen minutes.

The winning hunting team was "US-Red," made up of Mike McCarter KA7NOO, Lewis Osborn KC7MZ, and Ron Miller WB6JGV. All are members of the Northwest ELT Team of Vancouver, Washington. KA7NOO was second place individual hunter, and KC7MZ was third.

Second place team was "US-Blue," consisting of N6QAB and Southern California hunter J. Scott Bovitz N6MI. The Japanese team of Yoshiko Yamagami JQ1LCW, Zen-ichi Oba JN1JPX, and Tuk Tsukui JR1WYB took the bronze.

No hams on earth are more friendly or more interested in international goodwill than those in the Portland area. Despite the "Beat LA" signs in every store window (for the basketball tourney, not the foxhunt), they made everyone feel welcome and part of an important amateur radio event, with lots of promise for the future. You'll be reading more about FARS and international radiosporting in this column and elsewhere in *73 Amateur Radio Today*.

QUICKYAGI II..........$40.00

- 100% computer-designed yagis for non-tech users
- Auto optimizer, optimum gain, F/B & bandwidth.
- Auto/manual modes.
- 2 - 12 elements to 500 mhz.
- Fastest analyzer available; calculates gain, F/B, and impedances in seconds (instantly w/ math co-proc.).
- Log or linear el. & az. polar plots w/ beamwidth
- Easiest to use of all yagi modeling programs.
- Accuracy verified
- ARRL lab tested.
- Includes 2 versions: for math co-proc. & no math co-proc.
- Req. 360k & Hercules, CGA, EGA, or VGA graphics

These utils. are incl. in all "PLUS" pgms:
- Prog. time-zone clocks.
- 200 yr calendar.
- 15 min QSO timer.
- DXCC d-base w/ beam-head.
- Notepad w/ auto date reminder

These features are in all Log pgms:
- Prints mailing labels & batch QSL reports
- Scrolling log display w/ spreadsheet type data entry
- Hot keys.
- Prog. auto entries
- Search/modify files
- Tracking cell w/ sort
- Auto Call search
- Personal D-base
- Auto country entry
- QSL tracking
- On-screen help.

The following are in all "X" pgms:
- Kenwood Tx/Rx control & display.*
- Auto Rx log entries (log only).

The following are in all "II" pgms:
A fully integrated CW autokeyer w/
- 9 prog. TX buffers
- Macro keys
- 5-99wpm
- Auto SN
- RS-232 Tx key interface incl.

LETTERS

From the Hamshack

Bobby DeVito, Tampa FL I'm writing to let you know how much I enjoy your column in *73 Magazine.* I've been interested in amateur radio for almost 15 years now (I am 26), and just passed my codeless Tech exam last month. I am extremely thankful that I am now going to be a ham, and I will try harder to learn the code so I can be a General.

Even though I am a "no-coder," I still feel that I have as much or more to contribute to amateur radio as anyone. I've been involved in electronics since I was a child (my father helped develop the first GTE-Sylvania Technical Schools) and have been through the Navy BE&E and Electronic Warfare schools. I am a professional musician, working on my second album (sorry, but it's rock, not ragtime), and also do some studio engineering. And I've always loved ham radio! Now at least when I go on the road, I can take my HT with me and possibly make some friends, if they will condescend to speak with a "no-coder."

OK, now that I'm finished blowing my own horn, I can get to the heart of the matter. I really enjoy your column and I think that you are a positive force for the entire amateur community. You're a really good writer, and I enjoy your style. And your sense of humor.

You'll hear from me again. For now I'm stuck in VHF and UHF land, but I will make it to HF one day. If your ears can stand instrumental rock guitar music, I'll send you a copy of my last album, *Guitar Salad.* Hopefully, I'll be able to elmer some of my musician friends. Keep up the good work, and NEVER SAY DIE!

Sid Lynch KC4ZVJ, Jacksonville FL I would like to home-brew a 2 meter FM transceiver base station. Ideally, the rig will have repeater offset, digital frequency readout, and tone encode capability.

I'm having a great deal of difficulty locating construction articles or plans for such a rig. It seems that most construction articles focus on HF-QRP-CW rigs. Is there a reason for this, given the growth of the no-code Tech class that cannot legally operate such rigs?

Is it possible to home-brew a rig like the one I'm talking about without an electronics degree and a lab? I would appreciate any advice you may have that could lead me to information on such rigs.

I figure that if it is possible to get a decent VHF home-brew set on the air, this would open all sorts of other projects. For example, I would love to home-brew a packet station or perhaps get into satellite via home-brew.

Sid—You might want to check out Ramsey's 2m FM transceiver kit. They've been selling so well we haven't been able to get one for review yet.

As for a 2m FM total home-brew construction project . . . how about it, readers? If anybody's put together such a project, we'd love to take a look at it. . . . David N1GPH

Pete Stark K2OAW, Mt. Kisco NY I vote for "Poor Man's Packet" by WB2EMS and N8KEI as possibly the best ham radio article and project of the last 10 years, if not more.

I haven't built it yet, but I have a hunch the PMP project may have a feature the authors haven't mentioned: by eliminating the TNC with its CPU, etc., the PMP may also eliminate much of the QRM which normally makes it really tough to use an HT without a remote antenna.

Joel E. Dumont KA1LNJ, South Deerfield MA I have been a licensed amateur radio operator since 1984. This past spring, I upgraded to Technician, thanks to the encouragement of the Mount Tom Amateur Repeater Association's class, taught by K1MEA. I am now halfway to General class, having passed the written portion of the test.

I do not object to the possibility of paying a fee for an amateur radio license. In fact, I agree with the idea of paying $5 a year for the 10-year license. I sent cards to that effect to the representatives and senators listed in your July editorial.

I applaud your efforts to focus ham radio on fun, talking, and tinkering. After all, this is supposed to be a hobby, right? I think it is still possible for innovation to come from hobbyists, since most big companies tend to stifle creativity in the name of conformity and order. It may take a lot of money to develop and market things, but ideas come to those who have the time and interest.

W.E. Bennett N7IVM, Bellevue WA This time you've really done it. There are probably hams all over the U.S.A. who are foaming at the mouth! License fees!

Seriously, I have always felt that the decision to eliminate fees was a potential weapon to be used against amateur radio. My only reservation is whether it is possible to get the fees where they should be, into that section of the FCC which is concerned with our affairs. I don't want a free ride, but I would like my "fare" to help keep my "bus" on the road!

George C. Fennell N3EQE, Butler PA On the ham front in Butler County, things are really cookin'! I am pleased to announce that my latest Novice/Technician class yielded nine new ham operators to our ranks, six of them being "codeless Techs," and more are coming aboard due to the long overdue codeless license.

Also, ATV is alive, well, and being heavily promoted in the area. We are in possession of an ATV repeater and all the "goodies" to go with it, and have received permission from the local VA Hospital to place it in operation upon their rooftop tower. This location is prime, and will enable everyone in Butler and the county-wide area easy access to the machine. Right now there are seven individuals in the process of purchasing ATV gear, and many more contemplating the move.

Keep it up . . . you're our inspiration and guiding light!

Mark A. Stevens AB4YE This past lunch hour, I spent time reading over the last three years of gloom and doom from your editorials. Gasp! . . . I agree with you. We have no hope of keeping our frequencies with arguments to the FCC that we are a vital national resource, that the bands we have now are crowded, that we are on the cutting edge of technology, etc.

If we are going to be able to keep our frequencies . . . I think that we need to get down to basics. Business is going to do everything it can to lobby us out of our airspace. Problem is, there really is no room left for continuous growth of radio technology as it's now envisioned. As soon as they take our frequencies away from us, they will find that they still don't have all the room they need, and they will have to develop other ways of transmitting data for profit. (As archaic as they look now, phone lines hold more promise for data transmission than do radio waves.) One of our first priorities must be to convince the FCC of this fact: Ham radio's frequency space is only a small crack in the wall of physics that limits the amount of usable radio frequency space available for profit making. Once our ham bands are gone, they're gone for good . . . and for nothing.

We need to look at our ham bands as a valuable, disappearing national resource, just as we look at our national forests. As hams, we have to stop telling ourselves how valuable we are, how important our mission is, and start telling the government how valuable public frequency space is to the nation. We need to make it known to anyone who will listen that we love our radios the way some people love their campers or motorcycles or coins or guns. We need to make our case for our right to keep what we enjoy.

We need to cease being a bunch of emergency chasing, council meeting, jurisdiction disputing political idiots who do nothing but set up ego gratifying repeater councils and radio societies, then spend any remaining time trying to find someone to take to court. We need to become a unified group of hobby-loving individuals who will effectively let the world know how much we appreciate the little reserves of public frequency space we now have. . . .

We are not on a mission from God. We need our national parks, and we need our international frequencies . . . not because we are an asset to the nation, but because the frequencies are an asset to the public, an asset too valuable to leave entirely to business interests.

I, as a ham, am not an indispensable asset vital to the correct functioning of our military and emergency services . . . ham radio is an asset to me personally. I know that the world could get along without me, but I surely don't know what I (we hams) would do without ham radio.

Jeff Kinsman NH6VH From time to time we all get a bit disillusioned with amateur radio. Then something comes along to refresh our sense of wonder and faith in hams and the hobby. Something like that happened to me last spring when we were in the Persian Gulf with "Desert Storm." I'm the chief operator of the MARS station onboard the aircraft carrier *USS Nimitz.* In addition to running phone patches via MARS, we've formed a group of amateurs to promote ham radio onboard. Anyway, as luck would have it, we "smoked checked" the finals in our amplifier when we got underway. Sure enough, when we arrived in the Gulf, we couldn't contact any MARS stations back in the states using a barefoot rig. With over 6,000 men on *Nimitz,* the need for contact with home is vital. We thought we were sunk—literally! To my surprise, amateurs all over the U.S. responded to our call for help. They stayed up late running patches (many times at their own expense), relayed message traffic, and generally kept our spirits high during a difficult deployment.

Their extra effort proved to me that although we have our differences in the hobby, when the chips are down, we pull together and bring out the best we have to offer. Isn't *that* the foundation of amateur radio—service to fellow citizens? The next time you're depressed after reading gloom and doom letters, ask a sailor from the *USS Nimitz* what he thinks of ham radio—your wonder and faith will be renewed!

Daniel M. Jordan AA9AN, Evansville IN I am writing this letter about contests on the amateur bands. I have been an amateur radio operator for 15 years now. I am 28 years old, and have a family. Since my job and my family take up a lot of time, I usually try to get on the radio on the weekends when I can. But it seems to me every weekend there's another contest.

Now, don't get me wrong; I have nothing against contests. I'm sure they're an exciting aspect of the hobby. But why should a few people's enjoyment ruin it for everybody else? I'm not saying do away with contests, but limit them to a certain portion of each amateur band. Just look at the contest section of each amateur publication and it's packed. Every little club has its own contest weekend. Before long, there won't be standard ham radio contacts, just one long 365-days-a-year contest. I ask that any ham who is tired of being interfered with to please drop the FCC a note and voice your opinion. Maybe together we can all use our radios again.

Daniel—Please don't bug the FCC. This is not a situation where they could or would do anything—except get even more disgusted with ham operators who come crying to them every time they don't like something. Why don't you try writing a clear and constructive letter to the organizations who sponsor the contests? They are the ones who can change the contest rules. Your idea has merit. Just make sure you direct your energy in a positive way—and toward the proper authority. . . . David N1GPH

Darrell Davis KC4KGN, Fort Meade FL I enjoy reading your editorials every month. I have been licensed for a little over two years now and have enjoyed every bit of it. I got into amateur radio because of computers and computer communications, and experimenting, which I enjoy. I do mostly digital on HF and very little phone except checking into the ARES Net on HF. I am an assistant E.C. for ARES here in Polk County. Only phone I do is on 2 meter FM repeater or simplex. Trying to get started in satellite. I am 22 years old, so you do not have to be an old-timer to enjoy this hobby.

I am afraid that your predictions will come true unless some changes are made. The old men on our bands need to get out of their "live and die by CW" attitude and realize that Part 3 of the Amateurs Code exists: "The Amateur is Progressive." I like your end-chewing of your readers to get them to think for themselves.

Postmaster: send address changes to *73 Amateur Radio Today*, PO Box 58866, Boulder, CO 80322-8866.

Audit Bureau of Circulations (ABC) membership applied for.

Contract: By being so nosey as to read this teeny-tiny print, you have just become legally obligated to *73 Amateur Radio Today* for the amount of one subscription. Yup, that's all. Just one measly subscription and you're off the hook for a whole thirty days. If you can't convince a friend to cough up a lousy $19.97 for 12 issues of the best amateur radio magazine out there, then why not buy a gift subscription for a deserving Novice, Tech, potential ham, library or school radio club?

NEVER SAY DIE

Wayne Green W2NSD/1

Wayne's Ego

Now and then I get a nastygram bitching about my inflated ego. I'm not sure why readers are concerned about me not having a low sense of self-esteem. Sure, I enjoy getting appreciative letters and I hate getting nasty ones. I particularly love getting letters from readers who tell me I've had a positive effect on their lives.

Yes, I do tend to aim my writing toward my more intelligent readers, but not out of arrogance or imperiousness . . . I just don't feel comfortable talking (writing) down to people. It isn't in my mind to say, hey, look how incredibly smart I am . . . look how much I know. I write to help people understand things. No one can be an expert on everything, including me. But I do feel a need to share the things that I've learned or enjoy with others.

I keep urging you to try new ham activities. But I haven't asked you to do anything I haven't done. I've done moonbounce, made many OSCAR contacts, worked seven states on 10 GHz, won Sweepstakes, VHF and DX contests, DXpeditioned from dozens of countries, worked around 350 countries, and so on. I helped pioneer NBFM, SSB, RTTY, SSTV, etc. I've built all kinds of gear . . . and I've had so much fun doing all this that I've probably been a nag trying to get you to share my fun.

Yes, of course I have an ego. You mean you haven't? And I like you to know some of my wins. But I also share my bad times with you . . . like my loss of *Byte*, one of the worst traumas of my life. And my bout with the IRS, which probably ties with the *Byte* epic.

Like most of you, I do dumb things. Like letting myself be talked into running for VP a few years ago. It seemed like a good way to get some exposure for my ideas on improving education, solving the welfare mess, and helping the homeless. I let my enthusiasm carry me away into lala land. I should have known that the media has virtually zero interest in constructive, creative ideas. They're after bad news, so they concentrated on my old IRS debacle. Bad news sells papers, and journalists aren't about to forget it.

I was reminded of that when an ex-governor of New Hampshire called recently and asked if I would consider running for VP again. I gather there is a lot of anxiety about Quayle and many politicians are looking for viable alternatives. Not me, thanks. I'm an idea person, not a politician.

As I said at the time I ran, my concept of the vice-president was that he should be responsible for running national affairs, while the president would handle the international stuff. That's almost what we actually got. Bush *has* been handling foreign affairs. It's just that, as far as I can see, no one's been running the country.

A corporate VP has responsibilities other than twiddling his thumbs, waiting for *the* call. A VP is usually responsible for running a major aspect of the business. Well, why should running the country be different?

I think we all agree that the country would do better with some management. Our educational system is a disaster. The drug problem hasn't improved, despite task forces and endless propaganda. Crime is still getting worse. I'm not aware of any changes in the welfare mess, in improving the unemployment situation, or helping ease the homeless problem. Look at the S&L, the BCCI and other banking messes, our decaying infrastructure, the HUD disaster, the continuing defense contracting and environmental messes! Quayle, what in hell have you been doing? Playing golf and making "good will" trips?

Medical costs are going up faster than inflation. College costs are zooming. Organized crime is stronger than ever. Heck, I'm up against 'em in *two* of the industries I'm in. With no national leadership, there's no reason to expect things to improve.

Yes, I probably could help with many of those problems, but I don't need the aggravation. No amount of money could get me involved with the bureaucractic quagmires involved. Not even my vaunted ego could do it. I'm very busy and happy doing what I'm doing.

Both Bush and Reagan have handled the situation well. They've kept their hands off running the country and blamed Congress for everything. Maybe you missed the 7/22 *Time* editorial (p.70) on exactly that subject. Too bad; you shouldn't.

To help amateur radio grow faster, I've started *Radio Fun*. I believe this will help lots of hams get more fun from our hobby. I hope it will make learning theory more fun. I hope it will make trying new modes and bands more fun too.

But I'm also in the middle of starting a new company to put out sampler CDs to help the record companies get their new releases selling faster. Major New Releases (MNR) is gearing up to put out two or more samplers a month. We'll be sending these CDs to some 10,000 record stores, bundled with our *Music Retailing* publication . . . and giving another 15,000 or so absolutely, totally, completely, 100% FREE to my *CD Review* readers.

My Adventures In Music (AIM) samplers (also FREE) project, each with tracks from 16 or so different independent record company releases, has been a huge success . . . and needs to be expanded.

Another new project is our *IMPS Journal*, which will go monthly to over 5,000 independent music producers. Then there's our *Guide to FREE Music*, starting in November. And more CD releases from my Greener Pastures Records. Yep, I'm busy. My only major problem is a desperate need for more people to help do all these things.

I'd love to organize ham tours to Europe, Africa and Asia. The hams there would love to meet us and host us. But travel costs money, and most hams seem to be terribly short of that. Where have all of you been while the banks were handing out billions? Were you holed up in your hamshack dit-dahing while the money trees were being stripped?

I remember one creative ham who went around the world, visiting rare countries and charging top dollar to DXers for contacts. He told me he was pulling down around a quarter of a million a year. I don't think he was exaggerating.

I organized a ham European tour back in 1963. It was a corker, with 73 of us on the trip. We had hamfests in London, Paris, Geneva, Rome, and Berlin. None of the hams on that trip will ever forget it! I see several of them every year at Dayton and they still remind me how much fun they had.

I tried to do another in 1965, but by then ARRL's "incentive licensing" proposal had gutted the hobby, and it was all over. I did conduct electronic and computer tours to Asia in the '80s, but we seldom had more than a dozen hams along . . . compared to 250 on the tours.

Now I'm planning some music industry tours, which should be fun. But wouldn't you enjoy going to Africa with me and getting on the air from 3D6 or 7P8? Wouldn't you like to visit ZS and talk with the local hams and get their perspective on what's going on down there? They'd love to have you come, I promise you.

Alas, before I can round up ham tour groups and lead them fearlessly to exciting new adventures, hams are going to have to have more disposable income. Any red-blooded ham would love to get on the air from a rare country and brave the pileups. Talk about ego! Suddenly you're a star and the whole world is groveling at your feet for the kiss of your QSL. Oh, if you only had the money, what a fantastic time you could have!

But making money means changing. Most people have never made any more money than they needed. Heck, they've never made quite as much as they feel they need. But making money means working harder, and we're all basically lazy, so we make do and begrudge those who do work harder the fun they can afford.

A few people either luck into it or are smart enough to figure out how to make more money without having to work so hard. It doesn't take a computer scientist to notice that entrepreneurs seem to have a much better batting average on getting rich than people working for the government, for large corporations or teaching. Hmmm, with the same amount of effort, you stand a chance of hitting the jackpot. Golly!

So I've been irritating the hell out of *73* readers for the last 30 years pointing this out. My ego does expand momentarily when I hear from a reader who's taken my advice and found it worked. But most hams . . . and for some reason this seems to be particularly centered on ARRL stalwarts . . . put me down as crazy and keep on staying poor. I've never met either a smart or a rich ARRL supporter . . . and I've sure met a lot of hams.

I used to spread my gospel via my computer magazines, too . . . and now I'm at it in my music magazines. Is all this ego driven? It doesn't seem like it to me, but then how many of us recognize our faults? I love it when I hear from someone I've helped . . . and I brag a little at the time. But I don't forget that gratitude is one of the least felt of human emotions, so I expect I'll have as many friends at my funeral as I did to support me when the IRS did a job on me. And, at 69, that funeral is getting closer. Makes it more difficult to make long-range plans . . . which hurts, because there's so much that needs to be done and so few people interested in helping.

Amateur radio is the greatest and most valuable hobby in the world. It should be spread to every third world country so they'll be able to cope with

QRX . . .

EDITED BY LINDA RENEAU KA1UKM

Calling All Hams

In March 1992, a space shuttle launch is planned with the first mission in a series of 10 flights called ATLAS-1 (Atmospheric Laboratory for Applications and Science). One of the payloads, SEPAC (Space Experiments with Particle Accelerators), will investigate the ionosphere and magnetosphere. SEPAC will use an 8 kW electron beam modulated as a VLF transmitter by audio tones between 50 Hz and 7 kHz. Attempts will be made to receive and record this signal on earth at various locations.

Since there are a limited number of ground stations, high school classes and the amateur experimental community are encouraged to participate in listening to and recording transmissions. The footprint of the VLF signals will be difficult to define without a large number of ground receiving stations. A low cost ($35 to $40) kit receiver has already been designed and tested by amateurs. The complete kit, with full documentation and project details, is available this fall.

The student effort has been dubbed INSPIRE (INteractive Space Physics). This will be the first time in history that such an extensive data taking capability has been available to space physics researchers. Some 10,000 high schools will be invited to participate. Participants will also benefit from the experience of assembling a simple but effective broadband VLF receiver, getting hand-on experience in obtaining scientific data, and coordinating a field station.

During the actual mission, amateur radio will play a vital role in relaying schedule changes for SEPAC transmissions. Amateur radio is already being used for daily premission communications regarding high school involvement. Most importantly, local ham clubs and individual amateurs can help students with kit building and setting up field listening operations. Individual amateurs are also invited to participate as ground stations during the mission.

For more information on the high school connection with project INSPIRE, send an SASE (two stamps) to Bill Pine, Science Department, Chaffey High School, 1245 N. Euclid Avenue, Ontario CA 91762. Interested hams and clubs should contact (also include a two-stamp SASE) Jim Ericson KG6EK, 226 Charles St., Sunnyvale CA 94086-6063. *TNX Jim Ericson KG6EK.*

New UHF DX Record

Two new microwave world records were set on Sunday, July 29, when Paul Leib KH6HME, at the 8200-foot level of the Mona Loa volcano, made contact with Chip Angle N6CA in Southern California on 3456 MHz at 2325 UTC. The short CW contact brought a signal report of RST 319 over the 2,471-mile long path. An hour later, at about 2425 UTC, Leib and Angle made a similar CW contact on 5760 MHz, setting a new world record for that band. Each of the stations was running 5 watts output to a 4-foot dish antenna, using equipment specifically designed for the path by N6CA. Both contacts were monitored, recorded, and verified by other amateurs living in the Southern California area. *TNX Gordon West WB6NOA and Bill Pasternak WA6ITF for their report in the* WESTLINK Report.

Photo A. Chip Angle N6CA in his record-breaking portable microwave station. Photo by Gordon West WB6NOA.

U.K. Novice License

Now that the first Novice licenses have been awarded in the U.K., the media is showing interest. On the BBC's "newsround," Natasha Weir 2E1AAE was seen contacting G3OUF/P, and Vicky Foster 2E1AAD was covered on BBC "Radio 5." Interviews are lined up for the TV program "Why Don't You . . ." and other TV and radio features are planned. These will be reported in full in a future issue of *Radio Communication.* Amateurs will now be hearing Novice licensees coming over the air, and all the help and patience given to these youngsters—and the not-so-young newly licensed—by experienced hams, will ensure mutual enjoyment of the hobby. Novice callsign prefixes are: England, 2E; Scotland, 2M; Wales, 2W; Isle of Man, 2D; Jersey, 2G; Guernsey, 2U, and Northern Ireland, 2I. In all cases, these prefixes are followed by either a Ø for Class A or a 1 for Class B licenses. TNX *WESTLINK Report, Number 607,* and GB2RS.

Reciprocity with Mexico

According to Rudy Baca of the FCC, the final reciprocal amateur operating arrangement with Mexico would be similiar to the agreement the U.S. has with Canada. "The goal is complete reciprocity with Mexico . . . the operating parameters are still being worked out. We expect to have a fairly detailed press release shortly. It is a matter of clearing everything with Mexico."

Over a year ago, near Mexico City, at a U.S./Mexico Consultative Group on Communications conference, Ralph Haller N4RH of the Private Radio Bureau suggested that reciprocity would be an appropriate topic. After a year of study and exchange of information, a second U.S./Mexico conference was held last July in Chestertown, Maryland. The FCC will issue a public notice describing all procedures in the reciprocal agreement when they are final. TNX *W5YI Report, Vol. 13, Issue #16.*

Soviet Goodwill Trip

David Larsen KK4WW, John Douglas NØISL, and Bob Fribertshauser W6YMR, members of the Foundation for Amateur International Radio Service (FAIRS), visited the *Radio Sport Federation* staff in Moscow last spring. The FAIRS members, also known as the "59 Group" were on a three-week goodwill mission delivering equipment to Soviet amateurs for emergency digital radio communication. Nine computers, nine TNCs, two HF transceivers, four HTs, and three VHF transceivers were donated by various companies. FAIRS Soviet amateurs involved in the project were Victor Goncharsky UB5WE, Yuri Katuytin UA4LM, Helen Goncharsky RB5WA, Victor Golutvin UB5WPR, and Vladimir Kiebanovsky UB5WCV. TNX *FAIRS.*

AREMIR

This month—October 2–12—an Austrian cosmonaut will operate AREMIR (Austrian Amateur Radio Experiment) aboard Mir. It will be part of a 16-experiment package called AUSTROMIR '91. AREMIR equipment will include a modified Alinco DJ-120E transceiver for 2 meters (power limited to 3 watts), a TNC and CW generator for the AREMIR beacon, and a laptop computer for packet. The exact frequency hadn't been determined at the time of this news release, but look for it around 145.8–146.0 MHz. Continuous packet bulletins are to be 36 characters long, with a six-second tone for Doppler measurements.

AREMIR has a strong educational focus, and an Austrian team of hams has created a special receiver for Russian and Austrian schools. TNX *SpaceNews, MCImail, John Magliacane.*

The Sudden Receiver

A simple-to-build receiver for 160–20M.

by Rev. George Dobbs G3RJV

It is sometimes said that the age of the amateur radio builder has gone. In the "great days," there was a huge electronic scrap yard left over from World War II, and hams could buy cheap parts and equipment just waiting to be modified for amateur radio use. They were good days; I remember well a local radio surplus store in my small home town in the north of England which had items that even a schoolboy could afford to buy. The store has now long since gone, and so have those bargain surplus items.

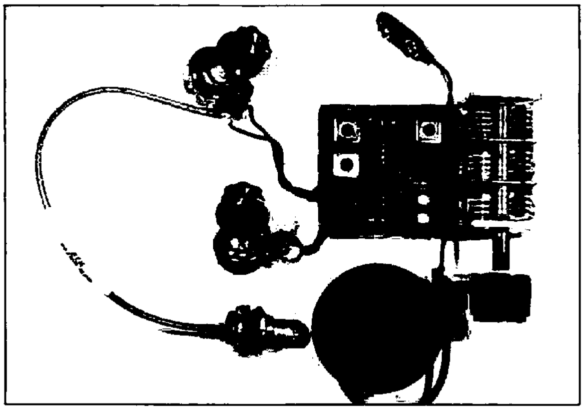

Photo. The Sudden receiver.

But my belief is that times have never been better for the ham who wants to build his own equipment. The world is full of electronics; from life-saving equipment to novelty junk, it is around us all the time. Smaller components, safer voltages and cleaner techniques mean that equipment can be built on a tray on the kitchen table—and cleared away after use. Components have never been cheaper; compare the price of electronic parts 30 years ago and now, and then compare average incomes. It is cheaper, easier and more convenient to build electronic equipment than ever before. I suspect that motivation, rather than means, is why more of it is not done.

There may not be the surplus items we used to find, but there is another kind of surplus these days. It is what I call the "scraps from the rich man's table." Modern technology has produced many specialized components and items for a particular job. If they are for consumer applications, the high sales volume often means that cheap, and sometimes clever, devices can be found. These may not be for applications directly related to amateur radio, but that is the joy of the new surplus market. The fun is taking cheaply produced devices designed for special applications, and making them fit what we want to build. That is real amateur radio in action!

In the UK there have been indications in recent years of a revival in home construction among radio hams. This has been shown by the popularity of the G-QRP Club and its little journal, SPRAT. The club has always leaned heavily towards the use of home-built equipment, and SPRAT has grown into an informal constructor's magazine. Perhaps part of its popularity is due to the number of simple construction projects that have been published in SPRAT. Many amateur radio constructors in the UK have found their first radio project in its pages. I proffer all this cheerful information because I edit SPRAT, and for many years I have tried to include projects suitable for the beginner.

In the past, SPRAT has contained many simple HF bands transmitter circuits which can be built in an evening with a few parts. These give the experience of working on an amateur band with a few watts of home-generated RF. *[Ed. Note: Those in the U.S. can join the G-QRP club and receive SPRAT for $12/year from Luke Dodds W5HKA at 2852 Oak Forest, Grapevine TX 76051. Overseas readers can obtain more information directly from the author.]*

Recently there have been requests to provide a very simple receiver circuit for the amateur bands capable of being built by a first-timer and yet able to yield reasonable results on the amateur bands. The Sudden Receiver was the result of this request.

The Sudden Conception

The name "Sudden" has nothing to do with the speed and ease of building this little radio (even though it is simple and easy to build); rather, it is the name of the town where it was conceived. I live in Rochdale, a

town in the northwest of England, in an area called Sudden. Sudden was once a village in its own right, and has a fine, stone-built Church of England church where I serve. I am the Vicar of Sudden, who just happened to design a simple radio receiver.

The Sudden could be described as a generic NE602 direct conversion receiver. It uses that fine and useful chip, plus the ever-popular LM386 audio chip. Another requirement of the design was to avoid the use of hand-wound coils, a common source of problems for beginners, and incorporate commercial inductors. The final design used a range of TOKO coils, given the UK designation KANK - - - - . *[Ed. Note: In the U.S. the TOKO prefix is BKXN-K.]* These have a range of inductance values useful for shortwave applications.

The NE602 is a fine example of the kind of "rich-man's scraps" we have today. It was originally designed for cellular radio applications, but has found its way into many amateur radio circuits. The internal workings and pinouts are shown in Figure 1. It is indeed a useful device: a balanced mixer, RF oscillator, and voltage regulator all wrapped up in one small, 8-pin DIP package. All the main workings of a direct conversion receiver under one roof!

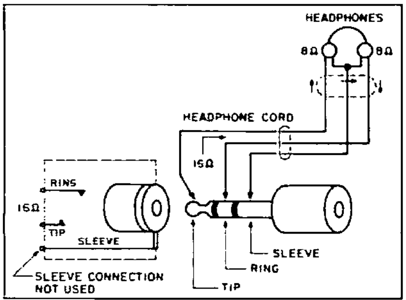

Figure 3. Walkman-type headphones can be used without changing the plug.

Circuit Details

The circuit of the Sudden is shown in Figure 2. It is a simple receiver having only two active devices and three inductors. The input comes via a simple attenuator, the judicious use of which is essential, especially on the 40 meter version in the UK. T1/T2/C1,2,3 form a bandpass filter. The band chart table gives values for the appropriate TOKO coils. The values are calculated to give a flat response across each band. Once the filters have been peaked with the coil cores, there is no further need of adjustment during operation.

C7 couples the signal into one port of the NE602. The mixer is operated single-ended, which is a compromise in favor of simplicity. A similar design, the Neophite (QST, February 1988), used a balanced configuration. In practice I have found that the results with this circuit did not warrant the extra complexity in obtaining a balanced input and output.

The oscillator portion of the NE602 is around pins 6 and 7. Looking at the circuit, if it is turned sideways, experienced constructors will recognize the popular parallel tuned Colpitts oscillator. Tuning is by means of T3 with VC1 and C10. The prototype receivers used a surplus variable capacitor which has three gangs of approximate values: 10 pF + 10 pF + 20 pF. It may be possible to find a similar capacitor (see the Parts List), or you can use a single section variable capacitor. It is essential to use a good quality air-spaced capacitor. The values on the band chart show the values for C10 when using the prototype variable capacitor. With other capacitors, some experimentation will be required. The kit version of the Sudden uses the values and the capacitor from the table.

The single-ended output is coupled via C11 to a volume control, then into the LM386 audio amplifier. The LM386 is configured in as a 200 times gain amplifier with a simple Zoebel filter R5/C17 on the output. The audio output will drive a small speaker, but is designed for headphone reception. A pair of Walkman-type headphones are adequate for the receiver (see Figure 3). It saves family arguments if you are using in-house teenager headphones on the receiver.

Figures 4(a) and (b) show the layout of the receiver. The receiver fits onto a printed circuit board measuring 2" x 2". The board shown here has been extended to mount the three-gang variable capacitor used in the prototype receivers. This portion can be cut away to give a smaller size with the variable capacitor mounted remotely from the board.

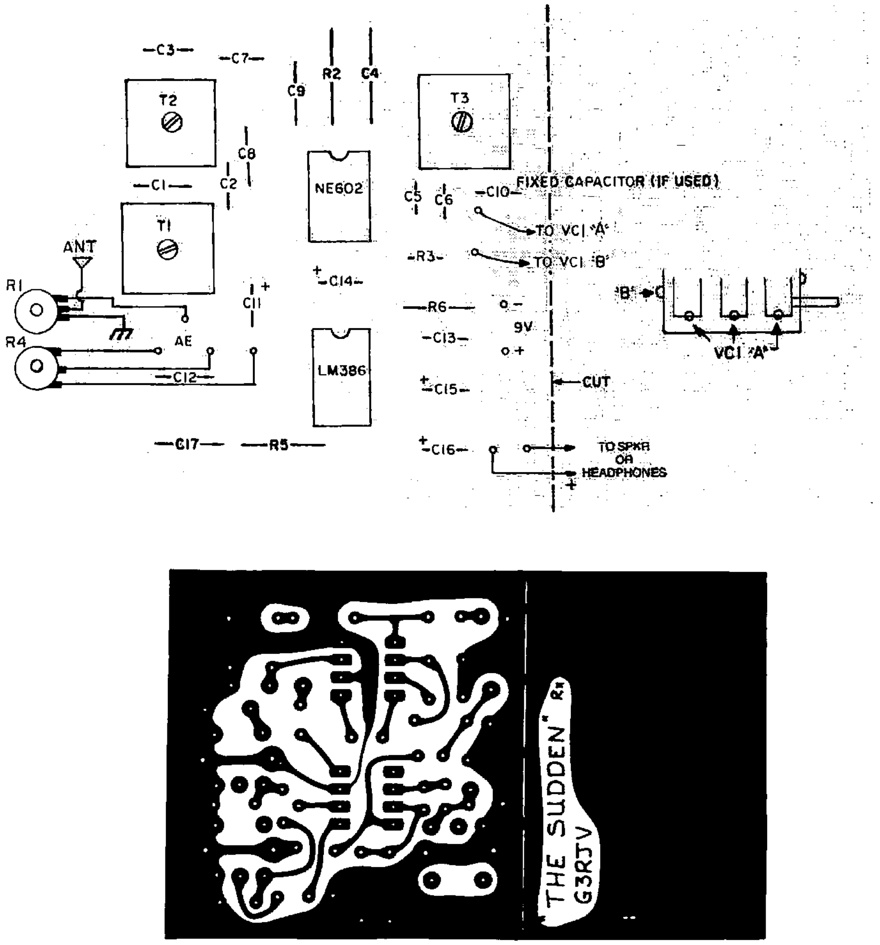

Figure 4. (a) Parts layout for the Sudden Receiver and (b) the foil diagram.

A kit of all parts including the PC board, the TOKO coils and the tuning capacitor is available in the U.S. for $29.95 + $3 shipping from Kanga US, c/o Bill Kelsey N8ET, 3521 Spring Lake Dr., Findlay OH 45840. Tel. (419) 423-5643, 7-11 p.m. Eastern. Kanga US will supply the blank PC board separately for $6 + $3 shipping. The complete kit is also available overseas from Kanga Products, 3 Limes Road, Folkestone, Kent CT19 4AU, Great Britain.

Variable tuning capacitor VC1 is also available as part # 2311007 from A.R.E. Surplus, 15272 S.R. 12E, Findlay OH 45840. Tel. (419) 422-1558.

The TOKO coils are also available from Penstock at (800) 736-7862.

Finishing Touches

The casing and hardware for the Sudden is a matter of individual taste. The main tuning capacitor does require a vernier drive for best results. The input attenuator potentiometer, R1, must have a linear track and can be in the value range of 50 to 2.2k ohms. Sturdy wiring is required for good mechanical stability between VC1 and the board.

Tuning up the receiver is very simple. A signal generator or other low level signal source is helpful, but it can be tuned up with band signals. The first step is to get the oscillator on to the band. This may be done by connecting a signal generator to C7 and adjusting the core on T3 until the signal is detected. It is also possible to listen for the signal on another receiver. A simple wire from the receiver antenna laid over the NE602 should be enough to pick up the signal. The core, T3, is adjusted to give the best coverage of the band in question using VC1.

The bandpass filter does require a little more work. I have obtained surprisingly good results by simply peaking T1 and T2 on signals in the band. The best method is to feed a signal source into R1 and adjust T1 and T2 several times. Begin in the center of the band and peak T1 and T2 for best output. Then repeat this operation at either end of the band, ending finally by again repeaking in the center.

The receiver does have a conventional 50 ohms input impedance. It is advisable with such a simple receiver to attempt to match the antenna to the receiver. A good operating procedure is to turn up the audio gain control, R4, to the point where the internal noise of the LM386 just becomes a nuisance and then use the attenuator, R1, as the main gain control. This is a simple receiver, and hitting it with too much signal will bring out its worst traits.

The Sudden is capable of very surprising results for its simplicity. The morning that I am typing this text, a Sudden builder telephoned me to say he had been listening to VKs on SSB with a dipole and a Sudden on 20 meters. It is simple, it is inexpensive, and it is easy to build, but it certainly hears lots of stations. It makes a very good first receiver project or an ideal receiver for scouts or school groups.

Build the Sudden, and enjoy! 73

The All
NEW
Line of
NO-GROUND-ANTENNAE

ANT-Ventures presents a new concept in VHF mobile antennae. The unique design allows these antennae to function efficiently WITHOUT A GROUND PLANE. Perfect for use on those vehicles with plastic or fiberglass bodies. Great for portable or appartment use, these antennae can be mounted to wood or metal and also directly to the back of your radio.

Pre-tuned at the factory, these antennae provide operation across their designed band, with a VSWR better than 1.3:1 and a power rating of 200 watts. MARS/CAP operation is possible without retuning.

Model NG-144-1 mounts directly onto a SO239 connector and model NG-144-2 mounts into standard 3/8 mounts which are optionally available from us.

A 10M Sideband Transmitter

Add voice to your QRP station.

by Bruce Auld NZ5G

Described in this article is a relatively simple, VFO controlled, double-sideband transmitter with 1 watt output for 10 meters. It's capable of easy and comfortable communications. For example, while this transmitter was still breadboarded, with its innards splayed all across my station operating table, I contacted K7EVL in Wenatchie, Washington, on the first call. He checked my signal, and he, my two-year-old Katie, and I had a merry contact.

The sideband transmitter is designed for hams who are interested in construction. It is also aimed at hams who are neither technicians nor engineers, but who possess some knowledge of RF construction technique. Where possible I've used commonly found parts, commonly used values, and the smallest number of different parts possible. Unless you live in a major city, however, you may have to mail-order some of them.

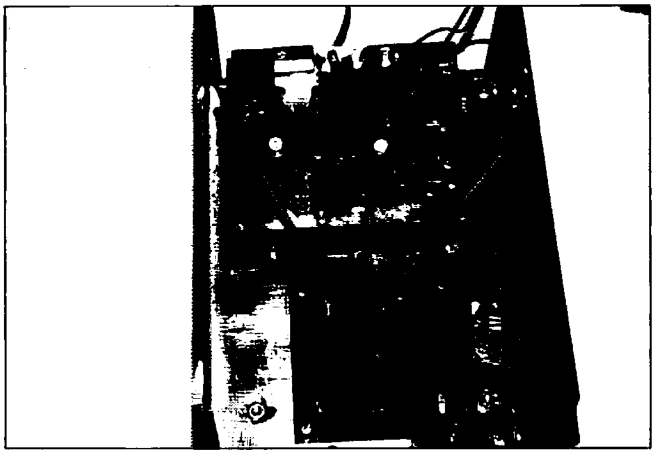

Photo A. A 10 meter transmitter you can build yourself!

This project is my distillation of the excellent work of W7ZOI and WA7MLH, whose projects taught me the vagaries of sideband generation. It employs simple, known circuitry with no surprises. It is not single sideband because of the added expense and circuitry to filter the unneeded sideband. However, with plenty of room to spare on 10 meters, this is no problem. The transmitter employs a manual transmit/receive scheme so that inexpensive microphones without PTT mechanisms can be used, and it is intended to be used with the ham's existing station receiver.

The Circuit

Figure 1, the block diagram, shows the flow of the transmitter. The whole of the circuit is designed in modules and interconnected to form a team. Constructed this way, it's easier to understand and troubleshoot.

Referring to Figures 2, 3, and 4, the transmitter is centered around an 11 MHz IF. This frequency was chosen only because I had a bunch of 11 MHz crystals on hand. Any convenient combination of frequencies for the IF/VFO combination can be used to reach the 28 MHz goal. The transmitter employs the simplest form of sideband generation, a single transformer and two diodes. It is fed with audio from the mike and its amplifier, and mixed with the 17.5 MHz VFO signal. In order to place the VFO frequency as low as possible for stability, a mixing scheme was used (hence another 11 MHz crystal). For this purpose, the magical NE602 was used, which is a wonderful device. This chip is a double-balanced mixer boasting an

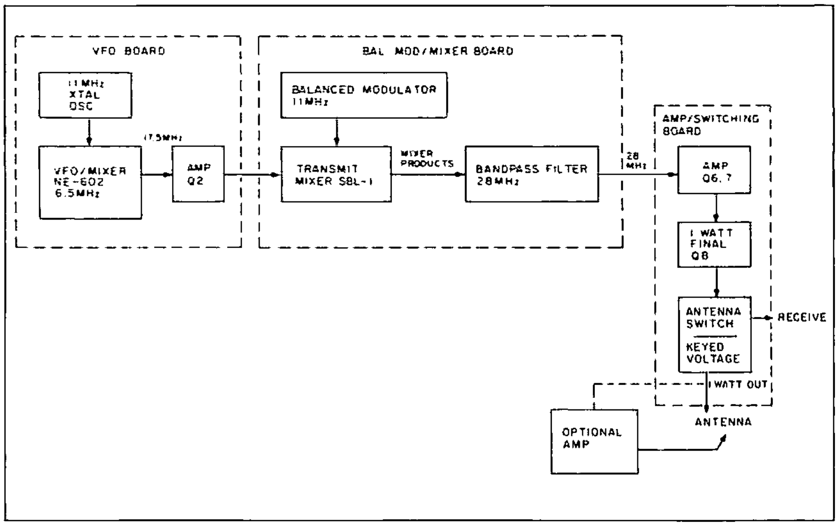

Figure 1. Block diagram of how the 10 meter sideband transmitter works.

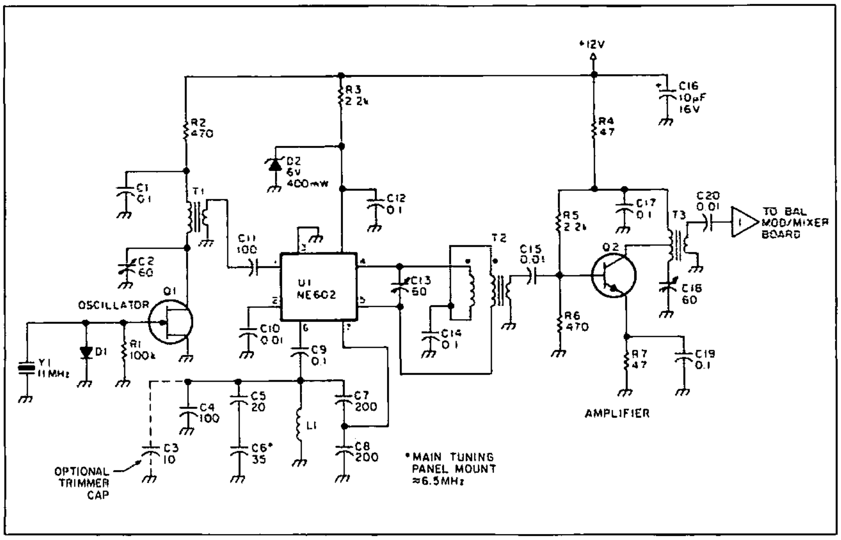

Figure 2. The VFO board.

onboard oscillator. A very respectable signal can be developed with one of these.

The signals from the sideband generator and VFO are amplified and fed into a diode-ring mixer module, U3. The jumble of frequencies that emerge go through a 28 MHz three-pole bandpass filter and a very nice 50 mV 28 MHz signal results. From here it only needs to be amplified. The next two stages are simple class A broadband amplifiers. The final amplifier transistor is the well-known 2N3553. In my unit, however, I use an inexpensive alternative, an RCA 4013 that I purchase from my friendly local parts merchant in single lots for 89 cents each. It performs equally well, and I appreciate the price more each time I destroy one experimenting.

The switching circuitry is designed to change the antenna from receiver to transmitter and to apply voltage to the amplifier chain during transmit periods. The NE602 VFO stage is free running for the sake of stability, but the carrier oscillator in the balanced modulator is normally off. This stage is switched on during transmit periods and for spotting your frequency in the station receiver. This is necessary because you would otherwise hear your carrier (though it has been suppressed) in the receiver all the time. These functions are carried out by a simple DPDT relay and two SPDT toggle switches.

Construction

The transmitter is constructed on three separate circuit boards. Their size was chosen mostly at random, but I have arranged them so that they will fit in a Radio Shack cabinet. The etching pattern and the parts placement guide are provided in Figures 5–7. The parts placement diagrams are viewed from the component side. If you use double-sided PC boards for the balanced modulator or the amplifier, be sure to rout out a space around each hole on the component side. I do this carefully with a ⅛" drill bit. Single-sided material should work just fine for these boards, however.

One may wonder why a single board is not used for this project. Briefly, I have

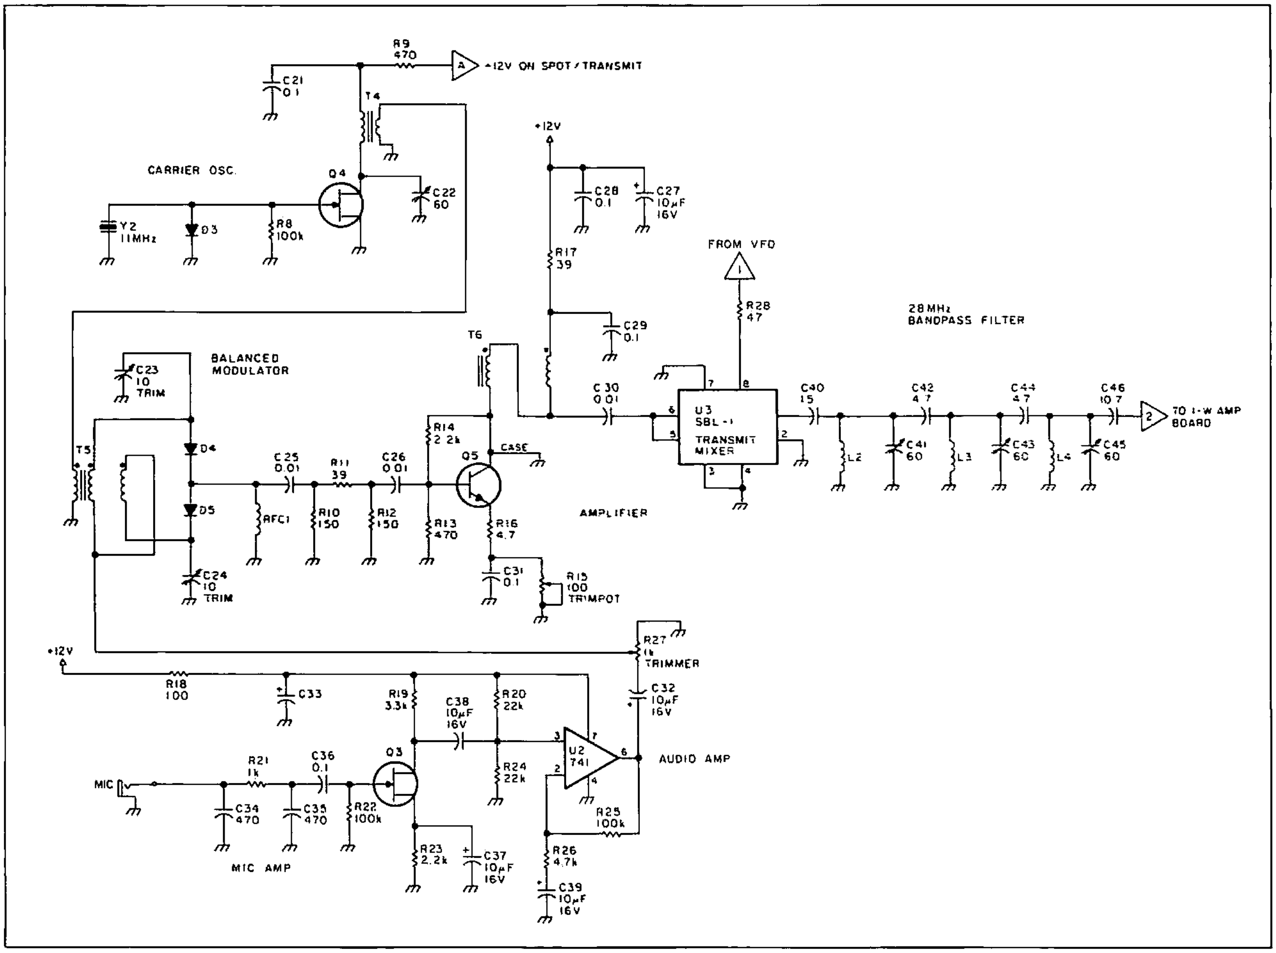

Figure 3. The balanced modulator/mixer board.

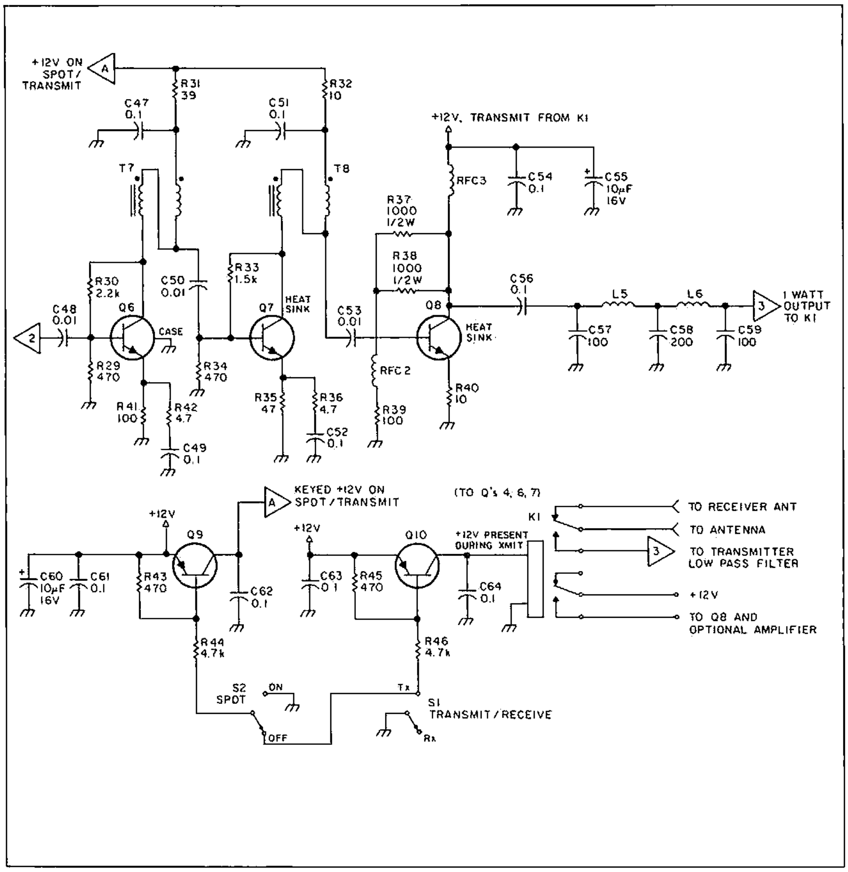

Figure 4. The 1 watt amplifier and switching board.

found that separating these stages greatly increases interstage isolation. Grounding is enhanced and a greater overall stability can be achieved.

I recommend that you build the transmitter in stages and get each stage running properly before you proceed to the next. Some hints for construction of the various modules are as follows:

The VFO

The VFO is the single most important part of the transmitter. If care is not taken to observe basic construction rules, the VFO will drift and you will be very unhappy with the rig. This PC board must be single-sided. Using double-sided board near the frequency determining components of the VFO will introduce unintended capacitance that's unstable with temperature change, causing drift. One frequently overlooked component in this regard is the tuning capacitor. Some home-brewers mounted them on a small square of single-sided board soldered vertically on the VFO board and directly behind the panel-mounted vernier dial. This mount actually forms one wall of the VFO compartment. If you follow this method, make sure the wall is not made of double-sided PC board. Of course, if you use a small aluminum box to house the VFO, this will not be a problem.

L1 lies face down on the board, glued in place after you have determined that the VFO is oscillating in the right place. I have allowed for a small trimmer for adjusting the VFO frequency, but squeezing together or spreading apart the turns of L1 will also work. Make sure that all of the parts coming off of pins 6 and 7 of IC1 are mounted as rigidly as possible.

The Balanced Modulator/Mixer

The balanced modulator/mixer board is the easiest to build and the least critical, except for the bandpass filter. Simply populate the board with parts. The spacing I have used for the pads on the board may not match your junk box parts, but I encourage you to use what you have. Notice, however, that the values for the fixed capacitors in the bandpass filter are rather specific. This stage is the most unforgiving of mistakes, and these values must not be changed casually. If you have no 4.7 pF capacitor, then try a 5 pF. Likewise, a 10 pF might be substituted for the 10.7 pF unit, but beyond that type of substitution, you may significantly affect the performance of the filter.

Note that there is a 6 dB pad (composed of R10, 11, and 12) at the output of the balanced modulator. This helps to achieve a good 50 ohm load for the balanced modulator, and the same input impedance for the following amplifier stage. Originally, I designed the trans-

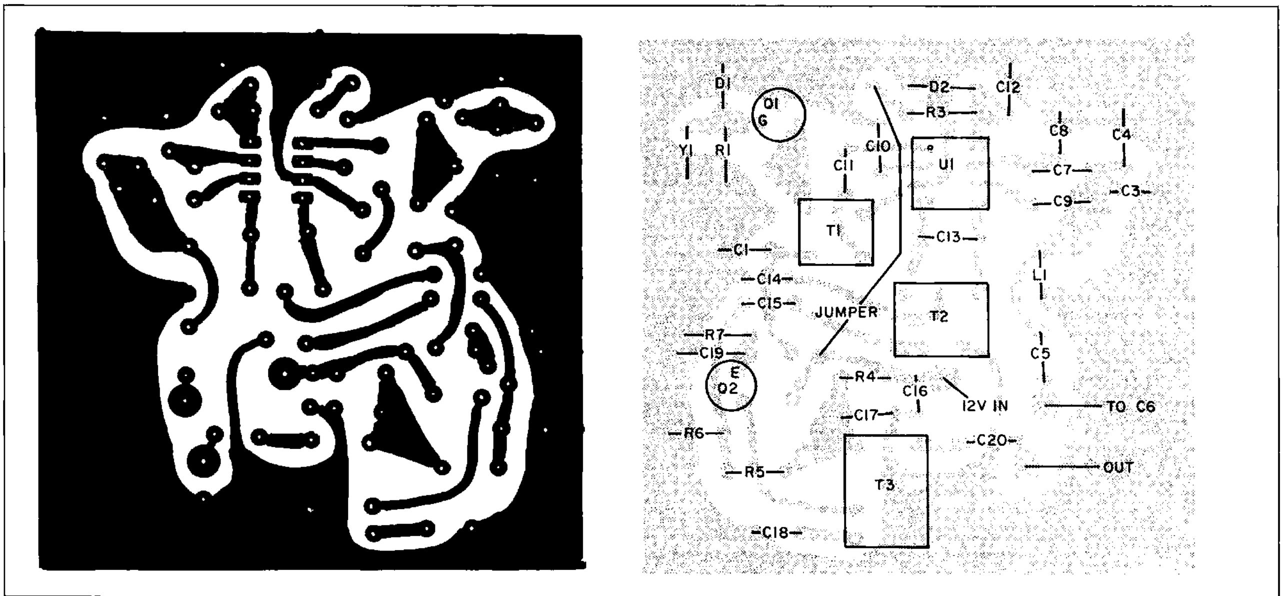

Figure 5 (a) The VFO foil pattern. (b) Parts placment.

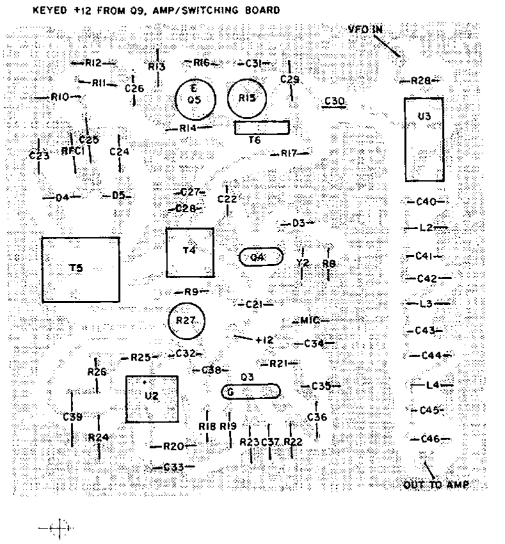

Figure 6 (a) The balanced modulator/mixer foil pattern. (b) Parts placement.

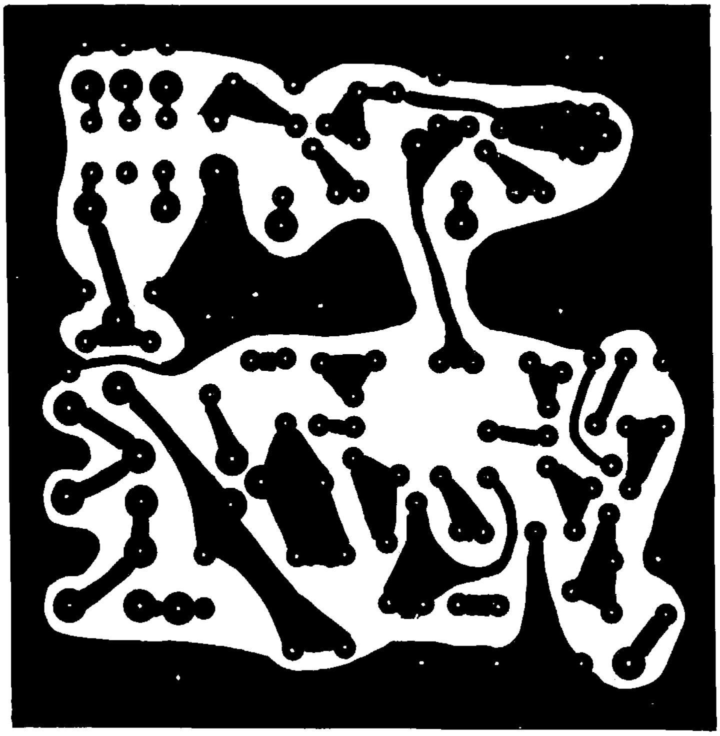

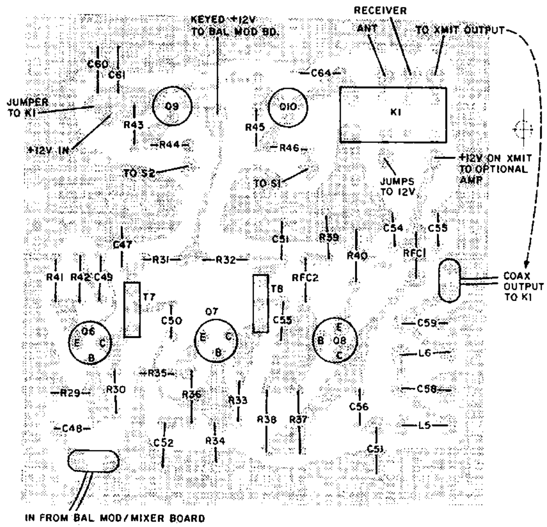

Figure 7 (a) The 1 watt amplifier/switching board. (b) Parts placement.

mitter with such a pad at the end of the bandpass filter, but found that the circuit was stable enough without it. Also, I wanted the 6 dB back! You may find that a pad at the end of the balanced modulator is not needed, and gain the energy otherwise lost heating the resistors.

The boards fit nicely into a Radio Shack cabinet. I double-decked the balanced modulator/mixer and amplifier boards on either side of a 10cm by 10cm PC board. The amplifier board is underneath because all the adjustable components are on the other board. You might consider making a cabinet of PC board material. It is drilled and cut easily, but plenty strong. If you can find a supply, you will save money on expensive cabinets. Done well, they can be lacquered or painted, and rival even the most professionally prepared cabinets in appearance. I also used a sheet of single-sided board as a false bottom in the cabinet. It helps establish a good ground plane.

Debugging and Tune-up

Viewed and constructed in modules, this rig can be assembled swiftly. Each module should be constructed and tested before moving on to the next. That way, a problem can be eliminated before it arises.

It is probably best to assemble this rig with access to a 35 MHz scope and frequency counter, if possible. If you are so lucky, your construction time will be drastically reduced.

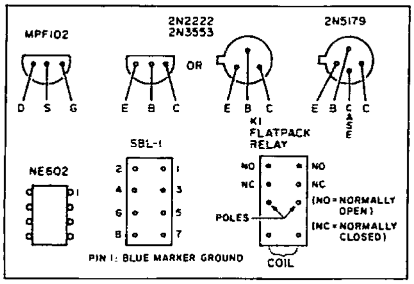

Figure 8. Base diagrams, all bottom view.

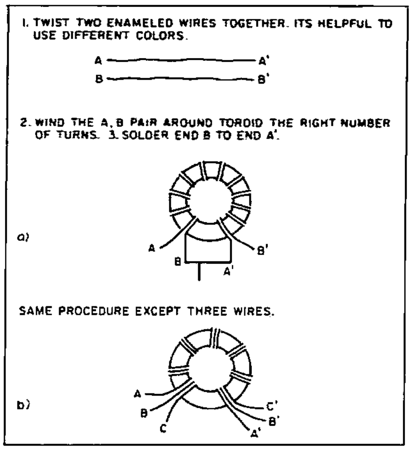

Figure 9. Winding the (a) bifilar transformer, and the (b) trifilar transformer.

Being able to see a signal on the scope and adjust the stage in question is a big help in a sideband project where you are concerned about speech waveform. If you do not have a scope, do not despair. You can probably adjust the transmitter a little at a time with the aid of the station receiver, its S-meter, and a sharp ear. I have adjusted RF stages this way, and while time-consuming, it can be done.

Construct the VFO and confirm that it oscillates at 6.5 MHz or so. Check this by placing the scope probe on pin 7 of IC 1. Confirm that the crystal oscillator, Q1, and its associated components, are running, by placing the probe at pin 1 of IC1. Tweak the output of the crystal oscillator with its trimmer capacitor. Before adding amplifier Q2, check to see that the product of the VFO frequency and the crystal oscillator is at 17.5 MHz or thereabouts. If the counter cannot "sit still" on a frequency, the desired product is not dominant. Tweak the IC's trimmer for maximum output at 17.5 MHz. Adding amplifier Q2 and tweaking its trimmer will further preselect 17 MHz and amplify it to about 3 volts peak-to-peak.

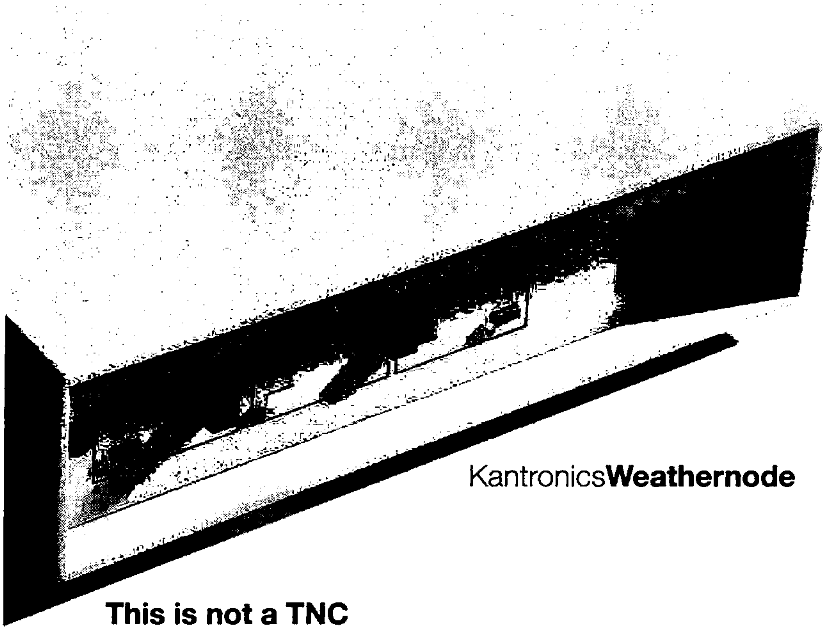
If you have no scope, you will have to find the oscillator's signal in the station receiver. Make sure you have the receiver's antenna lead close to the oscillator for adequate pick up. Adjust the same controls mentioned above for a peak S-meter reading.

C2 sets the VFO's bandspread at about 200 kHz. I chose 28.500 to 28.700 MHz, but adding a turn or two to L1 will lower the VFO frequency to the Novice portion of the band. Eliminating C2 will greatly increase the total bandspread.

Next determine that the balanced modulator carrier oscillator, Q4, will run. It is normally off except during spot and transmit periods, so you will need to temporarily apply voltage to it through its supply line resistor, R9. Peak its output. Plug in a microphone, adjust the audio gain (trimpot R27) for maximum input to T5 (clockwise) and holler. You should hear your best Donald Duck voice at 11 MHz, double-sideband. View the sideband carrier on the scope or listen to your signal n your station receiver and adjust the carrier balance trimmers (C23 and 24) potentiometer for the greatest carrier suppression. Even at maximum suppression, you will still hear a loud carrier in your station receiver. Adjusted properly, though, it will be undetectable by other stations. I have found that the audio gain trimpot is best set at about mid-range for best voice quality. Above that, significant clipping occurs.

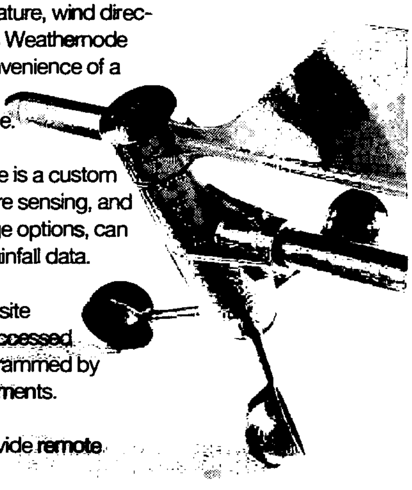
The tricky part of the rig is the bandpass filter. The jumble of products from mixing the balanced modulator and VFO frequencies are all present at its input, and you must preselect the 28 MHz energy, pole by pole. Start first at the top of L2 and rotate the trimmer until you find a peak of 28 MHz waveform. Repeat this process at each pole. I have not tried this without a scope, and would expect this to be a rather frustrating part of the assembly if done by ear through the station receiver. Adjust the filter without voltage applied to the amplifier stages.

The rest of the circuit is broadbanded and not adjustble except for the lowpass filter. Final adjustment is made by tweaking every trimmer in the unit for maximum output on a wattmeter and spreading or compressing the turns on the coils in the low pass filter for greatest output. Take care that you do not



This is not a TNC

This device gathers weather data at your station and makes it available to others via an external TNC and a Local Packet Network. Members of the Packet LAN can simply ask for tables of temperature, wind direction or wind speed. The Kantronics Weathernode then provides this data with the convenience of a mailbox and with the speed of the most advanced technology available.



Included with the KTU Weathernode is a custom EPROM which provides temperature sensing, and with the weathervane and rain gauge options, can supply wind speed, direction and rainfall data.

The KTU is easily adapted to multi-site installations and may be remotely accessed with password protection and programmed by the sysop to your network's requirements.

The Kantronics KTU, the first to provide remote weather data to a Packet LAN.

Blank PC boards are available from FAR Circuits, 18N640 Field Court, Dundee IL 60118. VFO board—$4.50; balanced modulator/mixer—$7; and amplifier board—$7; shipping—$1.50 per order.

detune the bandpass filter such that it is preselecting a different VFO/balanced modulator product. I tried to avoid this possibility by choosing an IF far removed from 28 MHz. While this results in the necessity of a mixing scheme in the VFO circuitry, it made tuning the bandpass filter easy. The first attempt at this circuit employed a 24 MHz IF and 4.5 MHz VFO. This sounded great in theory, but I had practical problems differentiating between 24 and 28 MHz signals.

Beware of self-oscillation. Even these broadband amplifiers will oscillate if overdriven, or if a mismatch occurs between stages. This will result in a waveform that looks like you have a carrier present in the signal. You may look to the balanced modulator for the problem, but you may really have an amplifier oscillating. I have used many different biasing and feedback schemes for Q7 and Q8, and the resistors in these stages should not be changed casually. While it is tempting to change them to obtain more output, you may start an otherwise stable amplifier oscillating madly. Experimenting with some of these components will show what a delicate balance exists in a sideband transmitter.

Adjusted properly, your voice will sound natural in the station receiver, and the wattmeter will bounce merrily with your speech patterns, resting at zero with no speech. If your wattmeter shows a continuous deflection during transmit periods, some imbalance

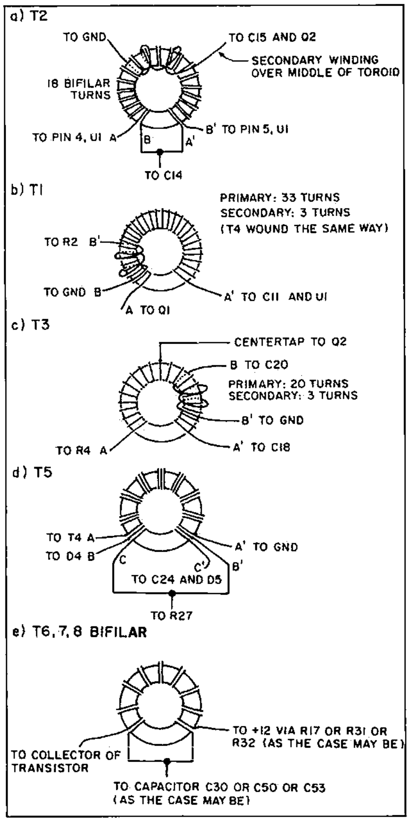

Figure 10. Winding specific toroids: (a) T2, (b) T1, (c) T3, (d) T5, and (e) T6,7,8.

exists. Go through the adjustment procedure again, watching the wattmeter. You should have about a watt peak envelope power. In one version I had more, in another I had less.

The spot function is enabled by throwing S1. It turns on the carrier oscillator and enables you to tune the transmitter to your receiver's frequency without applying a signal to the antenna. Simply speak into the mike and adjust the frequency until your voice sounds natural.

On The Air!

Ten meters is wide open. After completing the breadboard version of this transmitter, I was immediately rewarded with an enjoyable 1500 mile QSO on the first call. I had the same luck the next day. I have a modest beam antenna at a modest height. You will be pleasantly surprised at what a watt will do on 10 meters. While this rig will not duplicate the performance of the commercial transceivers, it performs admirably. Most importantly, it shows that a non-engineer and non-technician, on a first attempt at a sideband transmitter, can cook up a workable system. If I can do it, so can you! I welcome correspondence regarding this rig or any home-brew topic. Happy home-brewing!

Receive Weather Satellite Images and Charts on your PC with Quorum's Totally Integrated and Affordable Weather Facsimile System

Quorum introduces the first totally integrated system for the reception of weather satellite images directly on your personal computer. Selection of HF NAFAX, GOES WEFAX, GOESTAP, METEOSAT, NOAA and METEOR APT (including satellite downlink frequency selection) are made under complete program control from your PC keyboard.

The easy to learn and use Menu driven program allows you to capture, store, retrieve, view and print images with a few simple keystrokes. Images can be colorized from a palette of up to 262,000 colors when using a VGA display.

System configurations capable of NAFAX reception start at $399.00 while fully capable systems can be configured for $1500 to $2000, providing professional quality at low prices.

Simple Gain Antenna for 903 MHz

Build it for under $25.

by Phil Salas AD5X

Building antennas for the UHF and low microwave bands generally requires quite a bit of metal work and some tricky adjustments to get good results. However, you can overcome some of these problems with a few relatively simple modifications to an inexpensive, commercially available TV antenna.

The antenna I used was the Radio Shack U-75 UHF corner reflector antenna (RS 15-1660), which costs just $16.95. It consists of one driven element and seven directors. (This antenna is actually called a "corner-Yagi-Uda-hybrid" antenna, which is a corner reflector antenna with directors.) The trick was to match this antenna to 50 ohms and optimize it for the 902–928 MHz ham band.

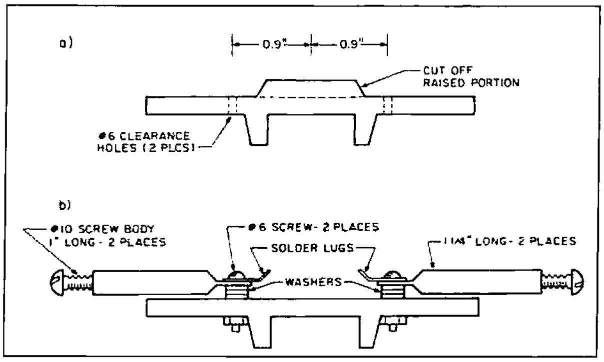

Figure 1. (a) Preparation of the plastic center piece. (b) Driven element preparation.

The Modifications

First, you must remove the insulated driven element by drilling out the center rivet holding it in place. Next, remove the aluminum elements from the insulated driven element by drilling out the two rivets holding them on. You should now be left with just the blue insulated piece. Now, referring to Figure 1(a), cut off the raised portion of this insulated piece with a hacksaw or band saw. Finally, measure 0.9 inch from the center hole and drill two holes for clearing #6 screws. This completes the modifications to the insulator.

Referring to Figure 1(b), cut two 1¼-inch pieces of ¼-inch copper tubing and flatten ½ inch of one end of both pieces. Drill a #6 clearance hole in the flattened portion on each tube. Attach these two tubes to the insulator with two #6 screws, nuts, solder lugs, and six #6 washers, as shown. Next, take two #10 x ¾-inch brass screws and insert them about halfway into the two copper tubes. Crimp the copper tubes so that the screws are snug in place. A type "F" TV connector crimping tool is excellent for this. This completes the driven element. Now, turn the screws completely into the tubes.

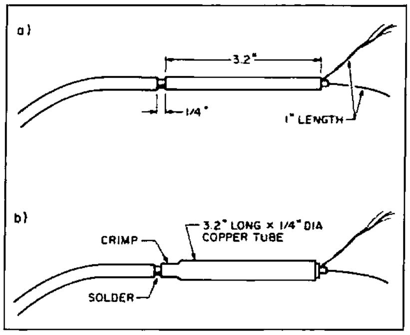

Figure 2. (a) Sleeve balun construction. (b) Crimp the balun and solder equal length leads onto the balun sleeve and center conductor.

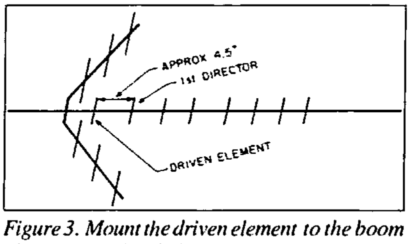

Figure 3. Mount the driven element to the boom about 4.5 inches behind the first director.

The Match

The driven element will just be a simple half-wave dipole which should give a good match to 50 ohms. However, the dipole is balanced and the coax is unbalanced so a 1:1 50 ohm balun is in order. Figures 2(a) and 2(b) show the construction of the balun. Use RG-8M coax cable (available also from Radio Shack). RG-8M is a miniature RG-8 coax which has an impedance of 50 ohms and the same diameter as RG-59. The loss characteristics of RG-8M are far superior to RG-58 and it is a perfect fit in the ¼-inch copper tubes.

Referring to Figure 2(a), prepare one end of the RG-8M by first stripping off 1 inch of insulation and exposing the braid and center conductor. Next, measure 3.2 inches more and remove a ¼-inch section of insulation, as shown. Now, cut a 3.2-inch piece of ¼-inch copper tubing and insert it over the cable, as shown in Figure 2(b). Overlap about half of the exposed braid and crimp the copper tube to hold it firmly in place. Using a 100 watt or more soldering iron or gun, carefully solder the tube to the section of braid. The open end of the tubing should be comfortably removed (0.1 inch or more) from the braid and center conductor. Now, cover the exposed braid/soldered tubing end and the entire piece of copper tubing with heat shrink tubing (from Radio Shack) and heat to shrink in place. You have just created a quarter-wave (3.2 inches at 915 MHz) 1:1 sleeve balun.

Now, solder the center conductor to the solder lug on one of the elements of the driven element assembly, and solder the braid to the other solder lug. Keep the lengths of the braid

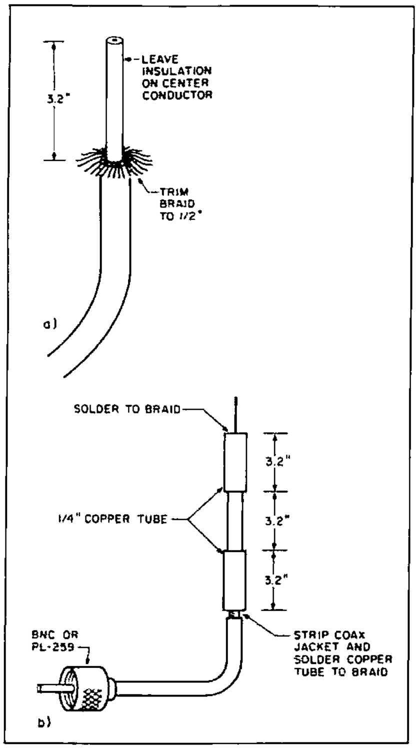

Figure 4. (a) Prepare the coax for the half-wave reference antenna. (b) Attach the sleeve and the RF choke sections of tubing as shown.

and center conductor as short as possible and equal in length.

At the other end of the RG-8M, add either a BNC or a PL-259 UHF connector. In either case, purchase a connector for RG-59 cable as it has the same basic dimensions as the RG-8M coax. A PL-259 with RG-59 reducer is the easiest connector to install. If you use a BNC connector, you will have to trim several of the center conductor strands from the RG-8M cable in order to insert the RG-8M coax center conductor into the BNC pin.

Finally—The Adjustment

To adjust the antenna, you will need a signal source and either an antenna bridge or an SWR meter. First, hold the driven element assembly out away from you and adjust the screws in no more than quarter-turn increments for minimum SWR of less than 1.5:1.

Now, place the driven element assembly on the antenna 4.5 inches behind the first director, as shown in Figure 3. Hold it in place with an 8-inch nylon wire tie (Radio Shack 278-1652). Watch the SWR and minimize it by carefully sliding the driven element assembly. If necessary, adjust the screws in the driven elements slightly. You should be able to get very close to a 1:1 SWR. Now, use either epoxy or hot glue to hold the driven element assembly permanently in place. You could also drill a new mounting hole through the boom and bolt the element in place. Also, re-crimp the copper tubing over the brass screws to make sure they stay put and make good electrical contact.

Reference Antenna

To see how much gain this antenna was really giving me, for comparison I built a half-wave sleeve dipole with an RF choke to isolate the coax from the antenna field. Figures 4(a) and 4(b) detail its construction.

Expose 3.2 inches of the INSULATED center conductor from a length of RG-8M coaxial cable. Unravel the braid and trim it to a length of ½ inch. Cut two 3.2-inch lengths of ¼-inch copper tubing. Slip one piece over the center conductor and down over the coax cable so that the RG-8M braid is under the tubing. Crimp the tubing with an "F" type crimping tool to hold it in place, and solder the tubing to the braid.

Slip the other 3.2-inch piece of copper tubing over the other end of the coax cable, positioning it 3.2 inches from the first tube. Carefully remove a band of insulation from the RG-8M, then crimp the tube over the braid and carefully solder the copper tube to the braid. Cover the entire assembly with heat-shrink tubing. Finally, add either a BNC or a PL-259 connector to the end of the RG-8M coax cable.

Attach a signal source and an SWR meter and snip off small increments of the center conductor until you have an SWR of less than 1.5:1. If you overshoot, just solder an extension wire to the center conductor and try again.

Measurements

My antenna-measuring setup consists of an ICOM R-7000 receiver with a Smith Design Spectrum Probe™ connected to the R-7000 10.7 MHz IF output. This gives me a tunable spectrum analyzer. I use a telescoping whip antenna for the R-7000 receiving antenna. Anything will work for this antenna as you are just going to look at the relative difference between the reference antenna and the corner reflector.

First, I supported the reference antenna about 20 feet from the R-7000. Then I connected a signal source to the reference antenna and made a note of the level on both the R-7000 S-meter and the Spectrum Probe oscilloscope output. Next, I connected the corner reflector and made boresight gain, side lobe suppression, and front-to-back ratio measurements. My setup is fairly crude, but I believe that the following figures are accurate to within 3 dB:

Gain:	8 dB
Side Lobe Suppression (90 degrees):	10 dB
Front-to-Back Ratio:	15 dB

An Inexpensive Solution

The gain antenna itself can be built for less than $25. Two higher gain corner reflector antennas are available from Radio Shack should you wish higher gain. The construction and set-up techniques in this article should be applicable to any of these antennas. 73

Microprocessor Repeater Controller, Part I

Add versatility to your repeater system.

by John Bednar WB3ESS

Not long after publishing an article on my Link Controller in the December 1989 issue of *QST*, I realized just how many repeater owners needed a repeater controller they could home-brew on a modest budget. My first single-chip microprocessor repeater controller had been in operation for almost 10 years. Before offering it to others, however, I decided to completely rewrite the software to add some new features. I knew that if the design were economical, it would bring those repeater owners with diode matrix IDers and intermittent touchtone control into the 21st century.

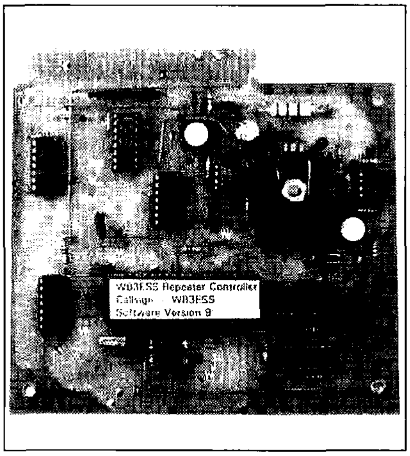

Photo A. The repeater controller consists of a computer board and an audio board. Shown above is the microprocessor board.

Selected Features

The heart of this controller is an 8749H single-chip microprocessor. To date, I am still amazed at how many features I was able to pack into it! Selecting the features required prudence, since the memory of the 8749H is limited to 2K bytes of EPROM. You could add external memory, but that would increase the size and cost of the finished product. It would also produce RFI, and you would have to mount the controller in a shielded box with feed-through capacitors to bypass the wires.

See Table 1 for a list of the features I selected. Macro capability, voice messages, reverse auto patch, and measurement of signal strength would be nice extras, but you'd spend seven to ten times more. The project in this article is for those who want an economical, easy-to-construct repeater controller with a wealth of useful features.

Overview of the Controller

The complete repeater controller consists of two circuit boards, one with the microprocessor circuits and the other with the audio and phone interfaces. With a modest junk box, you can build both of them for approximately $130. (I will be making the boards and programmed microprocessors available.) The microprocessor board (see Photo A) has nine outputs and two inputs for control and monitoring. All of these outputs are reserved for the user; they are not dedicated to any specific task.

Additional controller outputs are provided for autopatch, audio muting, repeater PTT, link PTT, and two outputs for the Link Controller Host PTT and Busy inputs. All user outputs are open collector type, able to withstand 30 volts, and sink 40 mA of current. The repeater controller has inputs for repeater CAS, link CAS, superuser, and link monitor, plus two reserved inputs for users to monitor things. All repeater controller inputs are CMOS, and offer a wide input voltage range to make interfacing easy.

Command Structure

The repeater controller has two priorities in the DTMF command structure: the "user" and "superuser" levels. None of the superuser commands can be executed when the controller is in the user mode, but all of the commands can be executed in the superuser mode. What's even nicer is that the owner can assign these priority levels to all of the 39 commands!

In most cases, you don't have to use the commands to change the CW speed, key-up delay, and hang-time available to all users. By restricting these and similar commands to superuser priority, they can not be executed unless the repeater controller is in the superuser mode.

When entering a command with superuser priority, the superuser pin must be low. If this pin input is high, only the lower priority user commands can be executed. This input pin can be connected to many different sources, the simplest being a controller output. Since output #1 is adjacent to the superuser pin, a solder ball across these two pins on the card edge connector will make the connection.

Another interesting source for the superuser input is a PL tone decoder output. With this type of connection the control operator would turn on a subaudible tone to enter superuser commands. With this type of external control of the command priority, the owner can adapt the repeater controller to whatever level of security is necessary for the environment.

Courtesy Beeps

When the repeater controller is in the non-link mode, you can choose a very short single beep, a short two-tone beep, or a no-courtesy beep. The decision to use the short single beep or the two-tone beep is based on whether output #9 is programmed high or low. I use this output to signal repeater users on whether a repeater function is on or off. By using this output to control some

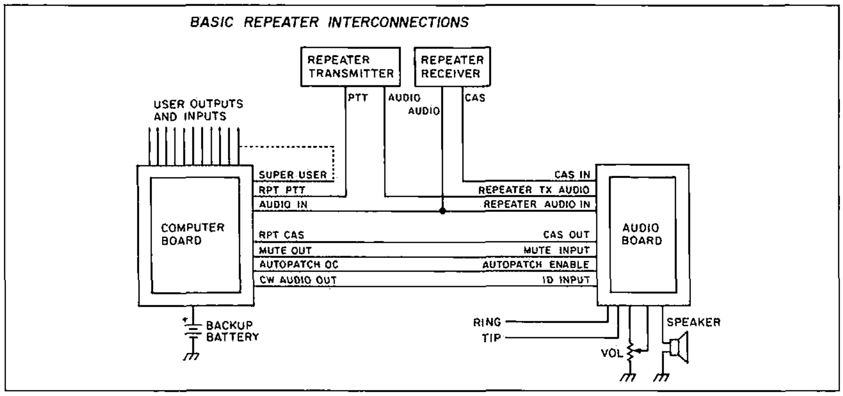

Figure 1. Block diagram of a basic repeater system using the repeater controller.

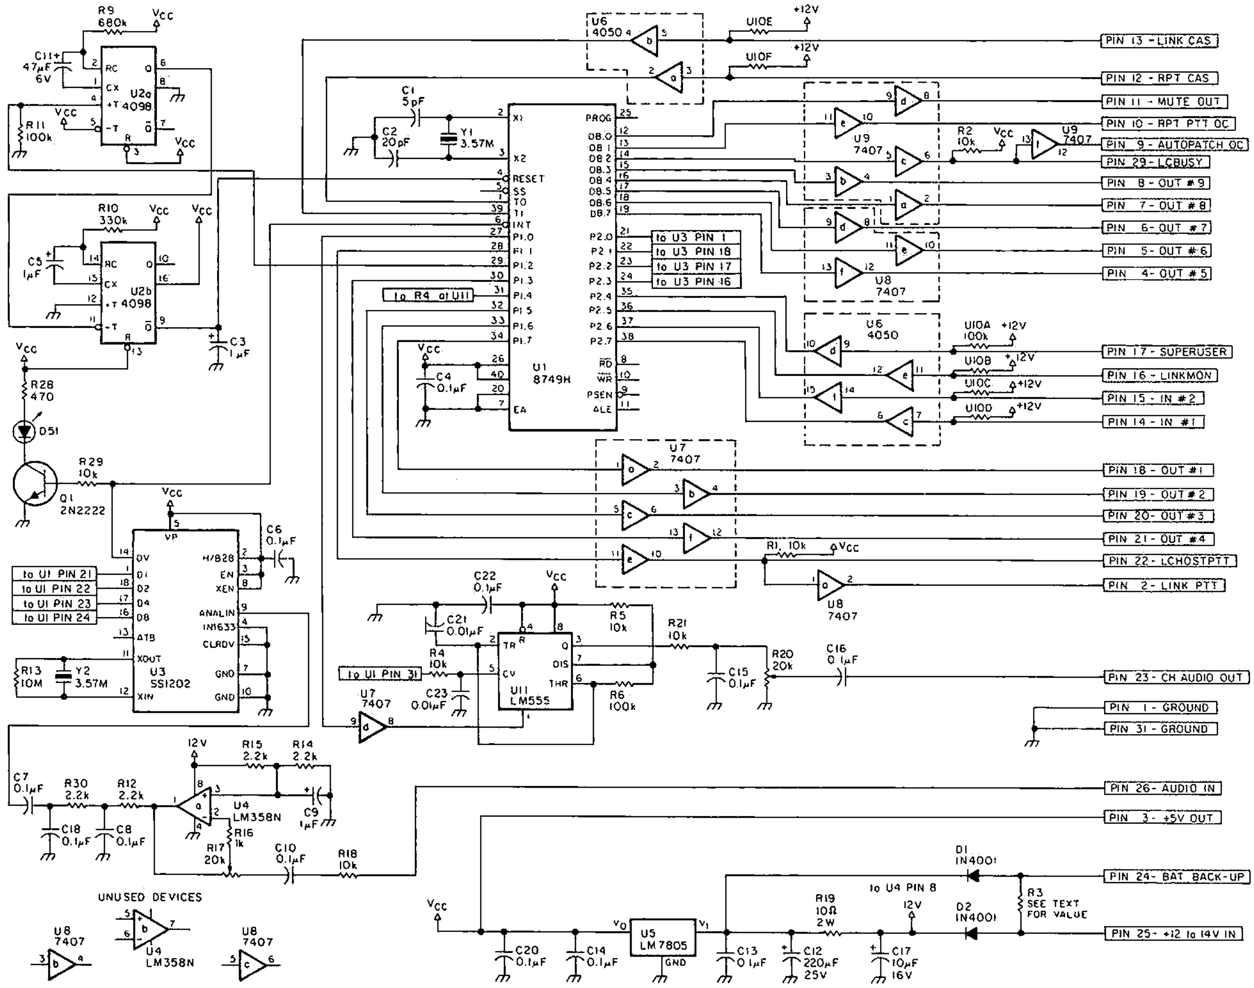

Figure 2. Schematic for the repeater controller computer board.

function, you can let your users know the on/off status of the function.

For example, you could use output #9 to turn the PL on and off. If you don't like courtesy beeps, you can simply program the courtesy beep delay to zero, and it won't sound during non-link operation! The link monitor input puts the repeater controller in the link mode via local or external control. (The repeater controller and hardware in this article is optimized for a repeater with a single link. You can add multiple links, but you have to build more hardware. I will include this information with kit orders.)

With this link monitor input, you can have an external device like a Link Controller turn the link on when a remote user wants to link into your repeater from another frequency. In link mode (linkmon input low), the computer uses an alternate set of courtesy beeps to let your users know that a link is enabled. If a user unkeys from the repeater frequency, a short double beep is sent; however, if a user unkeys from the link frequency, a dash-type beep is heard on the repeater. This simple selection of the courtesy beeps during linking operation instantly informs the users where the signals are coming from.

For additional flexibility, the pitch of the courtesy tones can be varied by changing components in the tone oscillator circuit (U11). Finally, if a user keys the repeater during the courtesy beep, the computer stops the tone so it won't interfere with conversation.

DTMF Features

Continuing with more features, the repeater controller can accept DTMF commands anytime, *even when sending CW.* When entering a command, the first digit must be valid for at least 200 ms. This is done to reduce the possibility of the controller being "triggered" by normal speech. Because of this delay, a short burst of the initial DTMF tone will be heard on the repeater, but all remaining DTMF tones will be muted.

Like the Link Controller, the repeater controller DTMF commands can be executed immediately by placing a "#" at the end of a command string. This feature can be used to control the repeater in the presence of other signals, or to string commands together. Normally, all DTMF tones are muted on the repeater and the link; however, by beginning a DTMF string with a "*" all remaining DTMF tones are transmitted over the repeater and link frequencies until the user unkeys.

This is useful for sending DTMF tones to a remote Link Controller board or some other external device. No need to worry about the initial burst of the "*" digit mixing up a remote Link Controller. Every Link Controller is already programmed to ignore invalid leading digits! Finally, an internal timer clears the DTMF digit buffer if the user doesn't unkey within three seconds of the last digit entered. This timer will aid the control operator if errors are made when commanding the repeater controller in the presence of other signals. If an error is made, the control operator simply waits three seconds and then re-enters the command.

Table 1. Repeater Controller Features

- Station ID, time-out timer, DTMF touchtone muting
- Nine outputs and two readable inputs for the user
- Programmable CW speed, hang-time, key-up delay, and courtesy beep delay
- Four-digit commands with programmable prefixes
- Programmable CW on/off read-back messages
- Programmable dual-priority level command structure
- Disable/enable repeater transmitters, link transmitter, time-out timer, and DTMF decoder.
- Autopatch and linking features
- Direct connect outputs for the Link Controller (uses commercial circuit boards and common parts)
- Multiple audio inputs and outputs with audio gating
- Phone interface, PL gating, and local speaker output
- All software, I/O, and timers are contained in one chip!

ID & Timeout

The repeater controller has a fixed ID interval of seven minutes, and the repeater will ID only when nobody is talking—unless the time-out timer ID is disabled. When disabled, the repeater will ID whenever the interval timer reaches zero (while users are talking).

To save valuable memory and eliminate extra transmissions by the repeater controller, I did not program the controller to do an "end ID." This is the type of ID routine where, a few minutes after the QSO has ended, the controller sends the station callsign and sometimes an extra message. I personally like a repeater controller without lots of chatter, and that weighted my decision.

To help reduce repeater key-ups caused by intermod bursts and dialing kerchunkers, I added programmable key-up delay to the software. When the repeater is being used, the key-up delay is unnoticeable. But after 30 seconds of no activity, the controller switches to the programmable key-up delay value, which is adjustable from 0 to 2.6 seconds.

The repeater controller time-out timer is fixed at the legal maximum of three minutes. Before the repeater times out, the controller sends a message to the users with a station ID. If the user is still talking, the transmitter, link transmitter, and phone patch are turned off. The transmitters stay off until the offender unkeys and realizes his mistake and transmits again.

There is no post time-out harassment from the repeater controller; that task is left up to the repeater users. Of course, if the repeater is timed out, a control operator can enter the command to disable the time-out timer, and the repeater transmitter will come on again. To be successful, the control operator must be able to capture the repeater receiver. The "#" feature must be used.

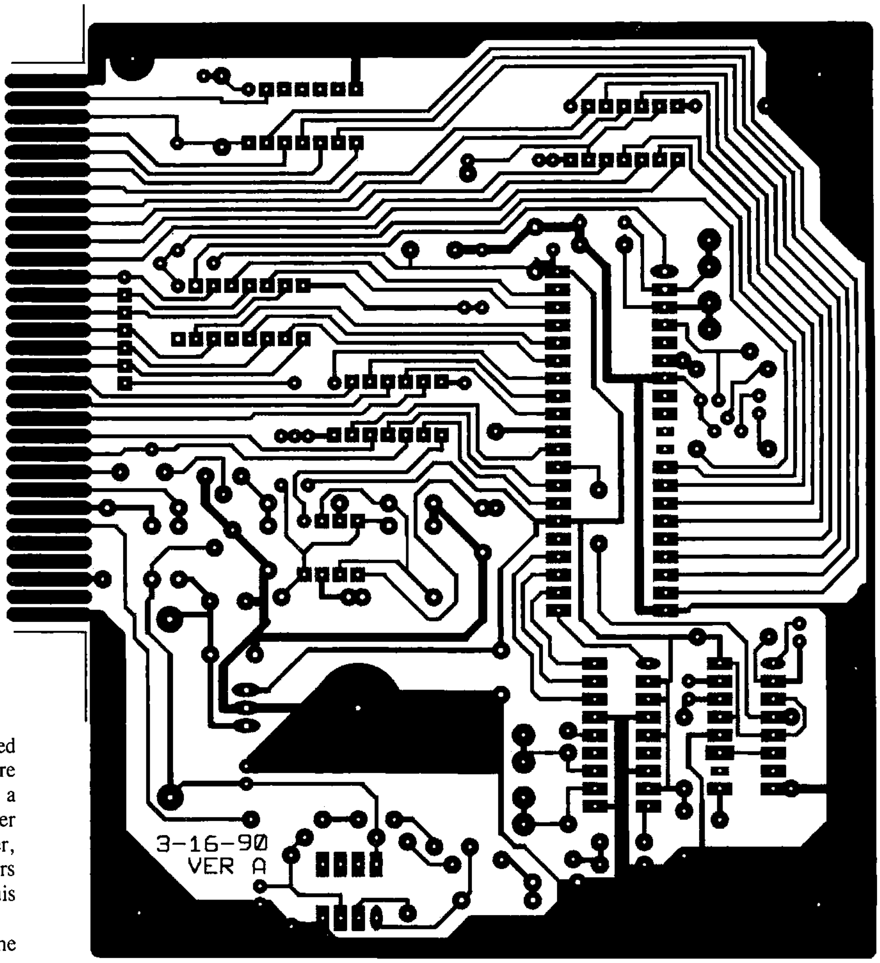

Figure 3. PC foil pattern for the computer board.

Autopatch

The repeater controller phone patch support is basic but novel. There really isn't enough memory to implement long distance lock-out, reverse patch, auto dial, or control from the phone. Despite this, the controller has several nice autopatch features.

For instance, when dialing the phone number, all digits are muted so that repeater listeners are unable to hear it. Additionally, there is an input on the computer board that allows owners to customize the autopatch with long distance lock-out or a patch limit timer if needed.

During autopatch calls, the microprocessor monitors input #2. If this input is pulled low, the autopatch will be terminated as if the OFF code had been entered from the touchtone pad. Since this input is scanned only when the microprocessor is not sending Morse code, the external signal will have to be latched until the patch goes off for correct operation.

Due to some clever software, this input functions identically to input #1 during non-autopatch periods. Therefore, input #2 may be *multiplexed* for both functions. The above features, plus being able to lock out users with the superuser priority, should aid control operators.

DTMF Commands

Initially, every repeater controller powers up with the same set of default commands. All commands are fixed at four digits long, except the editing commands, which are eight digits long. Since the leading two digits of each command can be edited, unique command sets can be created.

Because the repeater controller has two command priority levels, it's not absolutely necessary to change the prefix of all 39 commands. By making the access to the superuser function unique, 30 of the commands are instantly protected from outside parties (30 of the commands power up with superuser priority).

All commands are listed in Table 2, along with the power-up priority of the command. Most of these commands are self-explanatory. The four pairs of increase/decrease commands simply change timing values in the software. The owner can use a touchtone pad to increase or decrease timer values in fixed increments. The command can be repeated to make larger changes.

I chose this method for two reasons—it keeps the operation simple and it conserves precious memory. Although it's not as glorious as pro-

gramming delays in milliseconds, the result is identical. Also, my first repeater controller used this method of changing delay parameters, and it has worked well to date.

Command Editing

All of the controller commands have CW read-back to confirm the action, except for the autopatch ON command where it wouldn't make sense. To make the interfacing easier to the user inputs and outputs, I thought it would be convenient if I could control the *sense* of the CW read-back message. The power-up standard is output/input—high reads back as OFF and low reads back as ON.

If you like, you can reverse these messages when you're programming the prefix codes. Once again a simple but effective method was chosen to do this. To keep the standard read-back messages, program a 1, 3, 5, 7, 9, or A as the first digit of the prefix. To reverse the read-back messages, program a 2, 4, 6, 8, 0, #, or B as the first digit of the prefix. To eliminate the read-back message entirely, program a C or D as the first digit.

Since the "*" is reserved to pass touch tones, it can not be used as a valid first digit. If an "*" is programmed as a leading digit by mistake, simply program a new prefix with a different leading digit to correct the error.

You can program outputs #5 through 8 for pulsed low operation or a static (no pulse) function. Because of memory limitations, pulsed operation could only be added to the *output low* commands of these outputs. If a leading prefix digit of 1,2, or D is programmed, the output will pulse low for 150 ms and then return to a high state. Also, these three digits allow the owner to select one of the three possible read-back messages. If any other leading prefix digit is programmed, the output will behave like the other outputs (no pulses).

I am sure this flexibility in read-back messages is welcomed, as you don't have to invert signals in hardware to make the CW read-back message correct.

Since the above method worked so well, I decided to use the same scheme to program the command priority. To designate the command as user priority, simply select a 1, 3, 5, 7, 9, *, A, or C as the second digit of the command prefix; and as a superuser priority, select a 2, 4, 6, 8, 0, #, B, or D as the second digit.

To program a new prefix code into the controller, simply touchtone the following eight-digit sequence without unkeying: the four-digit "change command" code, and the two-digit "code number," and "new two-digit prefix." The software counts the number of digits entered, then checks the code number range. If no errors are detected, an "R" will be heard when unkeying, to confirm the change of prefix. Remember, the controller will clear the command buffer if you pause for more than three seconds between digits. If editing becomes necessary in the presence of other signals, just use the force feature "#" at the end of the eight-digit sequence.

All modifications to the power-up state of the controller are saved in the computer's RAM. Since the 8749H power-down feature wasn't usable in this design, I decided to provide battery backup power to the entire board. Everything needed for this is on the computer board, including the diode switch and the charging resistor (R3) for the battery pack. The computer board requires approximately 225 mA, so a pack of seven AA NiCd batteries will keep the board alive for close to three hours. If longer periods of backup are required, you can substitute a backup battery with greater capacity. To allow the charging circuit to function properly, the full charged terminal voltage of the battery must be at least 1 volt less than the power supply voltage of pin 25 on the card edge connector. If you notice that your computer doesn't retain programming changes after power loss, measure the voltage across R3 to see if charging current is flowing into the battery under normal conditions. For those owners who have a 6 volt battery pack lying around, a high efficiency regulator can be substituted for U5 (LM2940CT-5.0). With this regulator, the terminal voltage of the backup battery can be as low as 6.1 volts. Resistor R3 should be selected according to the battery backup scheme you use. If you power the computer board with a 13–14 volt supply, R3 should be 390 ohms (you can use either voltage regulator) when using a seven-cell AA NiCd pack; R3 should be 470–510 ohms if you use a six-cell AA NiCd pack (use the optional regulator). See the parts list for a good backup battery source.

Computer Board Operation

The heart of the computer board is the microprocessor U1. It controls the entire repeater controller. The inputs to the microprocessor are buffered by a 4050 IC (U6) and the outputs are buffered by 7407 open collector buffers (U7, U8, and U9). Pull-up resistors in a SIP resistor pack (U10) pull all the inputs to an idle state if the pins aren't connected. The board uses a 555

oscillator circuit (U11) to generate the CW tones for all IDs and messages. The resistors and capacitors in this circuit can be changed to modify the waveform and frequency. To change the pitch of the tone for some IDs and courtesy beeps, the microprocessor pulls pin 31 low. Resistor R21 and capacitor C15 form an RC filter for the tone oscillator, and pot R20 is used to adjust the CW ID level.

The computer board uses a DTMF decoder (U3) and an associated audio buffer (U4) to decode the DTMF tones. The gain of the circuit is controlled by pot R17. A filter after the op amp (R30, R12, C8, and C18) rolls off discriminator audio before passing it to the decoder chip. When the decoder chip thinks it detects a valid DTMF tone, pin 14 of U3 goes HIGH, signaling the microprocessor and lighting the LED DS1. Occasionally this LED may flash briefly during normal speech. If it occurs at a high rate, the filter after U4 may have to be modified.

The watchdog circuit (U2) monitors the microprocessor and resets the computer if the program stops execution. Pin 4 of U2 is continually pulsed by the microprocessor. If the program stops execution, these pulses will disappear, and after 8–15 seconds of delay, the watchdog should reset the microprocessor. When this happens, a power-up message will be sent on the repeater, and all default commands and parameters will be reloaded into memory.

It's important to connect a DC backup source to the battery backup pin to protect the microprocessor from being reset and loading the default parameters. Without a backup battery, power supply glitches may occasionally scramble both the microprocessor and the watchdog circuit. These cases are rare and they seem highly dependent on the transient suppression of the main DC supply.

The remaining circuits on the board provide regulated 5 volts to the board. If the supply voltage drops, the backup battery will provide power to the board through diode D1. Diodes D1 and D2 form a DC switch, and resistor R3 charges the external backup battery. If a nonchargeable battery is used, this resistor must be removed.

Parts are available from: **Digi-Key Corporation**, 701 Brooks Ave. South, P.O. Box 677, Thief River Falls MN 56701-0677. Phone: (800) 344–4539; and **Mouser Electronics**, 12 Emery Avenue, Randolph NJ 07869. Phone: (800) 346–6873.

The computer and audio blank PC boards and a programmed 8749H microcontroller chip are available for $19 each from John Bednar WB3ESS, 548 Cherryville Road, Northampton PA 18067. When ordering the programmed microprocessor, please include the repeater call as you want it sent, including the prefix (de) and suffix (/rpt) along with all spaces clearly marked. SSI 202 touchtone decoder chips are available in limited supply for $7. Please add $4 shipping for all orders. Foreign orders should include additional postage.

If you want to program your own controller IC, the source code is available in DOS format from the author at the above address. Send $10 and a formatted floppy (any size, any density). If you write the author requesting information, please enclose an SASE.

For battery backup, an assembled 7-cell NiCd AA battery pack is available from Cunard Associates. Phone: (814) 623-7000.

Assembly and Test Instructions

Before you begin assembly, here are some pitfalls to watch out for:

1. Don't attempt to assemble this board with a high temperature soldering iron or gun.
2. If the LED DS1 is installed backwards, it will give you the impression that the touchtone decoder isn't working.
3. Make sure resistor pack U10 is positioned correctly, and of the correct type (one common pin and the resistors internally tied to this pin).
4. Be aware that not all the ICs are oriented in the same direction.

Begin assembly by installing the 14 jumpers. Don't miss jumper J6; it's located under U1, an IC. Follow this by adding all IC sockets. It's important to install a socket for U1 so that the chip can be removed without damage and reprogrammed if necessary. Next, install the voltage regulator and heat sink and put a little heat sink compound on the regulator tab to aid in the heat transfer. Bolt the regulator and heat sink firmly to the PC board. Finish the board assembly by adding all remaining components.

Perform the initial testing with the ICs removed. Apply 12–14 volts to the +12V IN and GROUND pins of the board, and measure the regulated +5 volts at pin 40 of U1. If the supply voltage isn't within 0.25 volts of +5 volts, measure the voltage drop across R19. If this voltage drop is greater than 4 volts, look for a shorted trace somewhere on the board. Once the voltages are correct, remove the power and insert all ICs. Reapply power and re-measure the supply voltage. With all ICs installed, it should still be within 0.25 volts of +5 volts.

The computer board sends a power-up ID whenever the computer is powered up or reset. This power-up ID can be used to check the initial operation of the computer board. Two test methods will be given; the first requires an oscilloscope and the second a voltmeter. Connect a scope probe to pin 23 of the board and apply power. While monitoring the CW AUDIO OUT pin, the CW power-up message should be visible on the scope. If no tone is observed, it's possible that the microprocessor isn't running, or the 555 tone circuit is nonfunctional. The second test method checks to see if the microprocessor is running. First connect a resistor (anything between 1k and 10k) between pins 3 and 10 of the computer board, and attach a voltmeter between pin 10 and ground. When the board is powered up, the voltage on pin 10 should drop to near zero volts. After 6–8 seconds, this voltage should rise to near 5 volts. If this doesn't happen, the microprocessor isn't running or U9 is faulty.

When the above tests are successful, the watchdog operation should be checked. Using either test configuration from above, place a 1k resistor across the crystal terminals Y1 when the computer is sending the power-up message. The resistor stops the microprocessor oscillator and crashes the program. Within 8–15 seconds, the watchdog circuit U2 should restart the microprocessor and the power-up message should be sent. If using the voltmeter technique, the voltage on pin 10 should go back to 5 volts 6–8 seconds after the computer is reset.

Next month in Part II we will discuss the audio board and operation of the whole controller. ■

Kenwood's TH-77A Dual-Band Walkie

Super-packed with features!

Kenwood U.S.A. Corp.
2201 E. Dominguez St.
Long Beach CA 90810.
Tel. (213) 639-4200.
FAX: (213) 604-4487.
Price Class: $600.

To paraphrase an old song. . . look what they've done to my walkie, Mah. Wow, this new Kenwood dual-bander is a true technical marvel. Slightly bigger than the single-band TH-25AT, the new rig packs 2 meters and 440 in one handy package. OK, that's not big news anymore. But this rig has more features than I ever imagined could exist in one radio. That characteristic is both its strongest and weakest point.

First Impressions

The radio feels solid and well made. Unlike the TH-25, it has a nice, easy-to-operate PTT switch. All the buttons are on the front and one side, making them easy to find. The LCD is big and shows lots of stuff, including two S-meters, tons of status indicators, and both operating frequencies at once. As on most new rigs, the final zero is not displayed, and there is just a tiny digit for a final five. The display on this radio has a very low contrast. You must look at it from just the right angle to feel comfortable with it. The angle seems well chosen for normal handheld use but, in my overhead-lit room, at least, holding it at the "sweet spot" results in glare from the room light, making it hard to read the numbers. As on the new TH-27A, the display window is convex and presents the highest point on the face of the rig, making it a target for scratches.

The buttons are rubber or soft plastic, and although many are small, they are easy to push and widely spaced. The dual-band duck antenna is completely rigid plastic on the lower half, but flexible on the top half.

The power switch is a recessed rubber button on the side, above the PTT and MONITOR buttons. Being used to the traditional rotary switch on the volume control, I wasn't wild about this idea at first, but I have come to like it. The button is quite stiff, making it unlikely that it will be turned on by accident. Besides, you must hold it in for a significant fraction of a second or it won't work, further reducing the likelihood of accidental operation.

On top, there are dual concentric volume and squelch controls, one for each band. There's an oddity here, though: the main and subbands volume controls can be swapped depending on which band you are transmitting on, but the squelch controls stay fixed. It is easy to wind up with VHF volume and UHF squelch on one control, with the situation reversed on the other! It's not serious, but it can be confusing. Since squelch tends to be a set-and-forget operation, perhaps it would be better if the squelch controls were small, recessed knobs on the back of the radio. Overall, the rig feels like solid, professional gear in your hand. It has a nice, inviting quality to it—you just want to pick it up and talk into it.

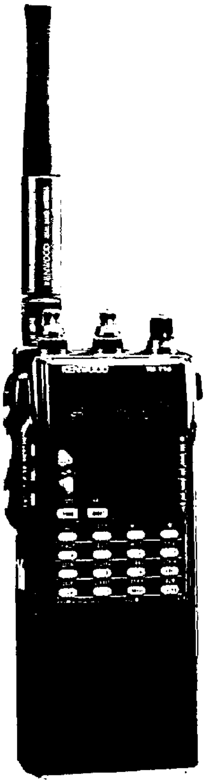

Photo. The TH-77A, Kenwood's compact dual-bander.

Pick a Feature, Any Feature

Let's see. . . we've got 42 memories, DTMF autodialing, simultaneous receive on VHF and UHF (or on two UHF frequencies at once!), CTCSS, DTMF paging and calling, Automatic Band Change, dual LCD S-meters, a direct DC power jack on top of the rig, the ability to route the two bands' receive audio to separate speakers, crossband duplex operation, and all the now-standard features like scanning, automatic and variable offsets, and so forth.

Unusual features include the above-mentioned ability to monitor two UHF frequencies at the same time. Note that I am not referring to "priority" watch operation (which the rig also has), but to actual full-time simultaneous receiving. Apparently, the second UHF frequency is monitored through the VHF front end, though, because the manual warns that in this mode the second frequency will exhibit reduced sensitivity. But what the heck, it still could be useful in a major metropolitan area like L.A., where UHF activity is extensive. The rig cannot simultaneously monitor two VHF frequencies; I guess the UHF front end can't be tricked into receiving VHF.

Other noteworthy features include the DTSS, or Dual Tone Squelch System. This system allows you to monitor a busy repeater without having to listen to the chatter, yet be called via a three-digit DTMF sequence. Also available is a paging function, which is somewhat similar to the DTSS but provides for both personal and group codes and also displays the calling station's ID code. There is a limitation to these features, which I'll discuss later on.

The LCD S-meter functions as a battery level meter on transmit (a nice touch), and the rig uses the batteries and most accessories from the TH-25 and '26 series. It includes a belt clip and two nifty covers. One slips on the bottom of the rig when you power it from the external DC jack on top and have no battery connected. This arrangement makes for very nice mobile operation, because all the cables exit from the same place and there is no exposed connector on the bottom. In this configuration, the entire radio is about the size of a microphone!

The other cover slips over the keyboard, protecting it from scrapes and damage. A flexible button is provided so that you can operate the FUNCTION key without removing the cover. By the way, the keyboard is backlit along with the LCD, and the lights can be locked on, making the rig much easier to use in the car at night. The lights are all LEDs (thank goodness, no more incandescent bulbs), so you don't have to feel guilty leaving them on for long periods. Naturally, you won't want to do this when using batteries, because the battery life will be significantly shortened.

Basics

As delivered, the radio receives from 136.000 to 173.995 MHz and 438.000 to 449.990 MHz, and transmits from 144.000 to 147.995 and 438.000 to 449.990. Interestingly, Kenwood's ads for the rig specify that it can receive 118–136 MHz AM (aircraft) after modification, but there's no mention of it in the manual.

MY GAP CHALLENGER DX-VI

Lew McCoy, W1ICP
CQ Technical Editor
(March 90 Review)

..."could actually hear signals that were in the noise on the beam. In my comparisons between the base-fed vertical and the GAP, the GAP consistently outperformed the base-fed antenna. Most of my reports were approximately one s-unit better with the GAP. One other surprise was that the GAP vertical was quieter (less noise) than the two base-fed verticals. I would rate the GAP as a quality product, but even more important a good performer."

Richard Morrow, K5CNF
73 Magazine
(October 90 Review)

"another very good thing about the GAP antenna is that you don't have to tune it. Usually broadband antennas are not very efficient, but this one is. If I could have only one antenna, I would definitely rather have this one. The lack of lossy coils, and the coverage of a very wide part of 75 meters by an all band vertical, impressed me more than a little!"

Kurt N. Sterba
Worldradio Magazine
(February 91 Review)

"These guys have solved a problem associated with verticals. That is, an awful lot of RF is wallowing around and dropping into the dirt instead of going outward bound. How does it perform? Like a hot knife through butter. I was just a barefoot boy answering the CQ callers. They just kept coming back to me. POW! POW! POW! I am almost struck with disbelief myself. I mean, this is a vertical. But then, it's a vertical with a big difference. I was indeed pleased. If I were a whole lot younger and I had two of those GAPs phased, I'd tell those contest hotshots to . . . look out!"

CIRCLE 172 ON READER SERVICE CARD

There is a mod which will enable aircraft RX, crossband repeat, and even reception of some other non-ham bands. Naturally, you're not supposed to do it, but also naturally, the procedure is already floating around. When will they ever learn that we hams don't like secrets kept from us in our expensive purchases? If they didn't want us to do the mod, they either should have made the advertised aircraft band RX a standard feature or not advertised the capability in the first place.

As on most of the new miniaturized walkies, the speaker is small and somewhat tinny, and there's not a great deal of audio output. It's not bad at home, but it can be hard to hear the rig in a noisy car or pickup truck. I can't fault Kenwood here; that's just as good as it seems to get from a speaker that small. The transmit audio is crisp and clean, as is usual in Kenwood rigs. The mike is somewhere inside the speaker cutout, but I can't see it on this radio. It doesn't matter; if I talk at the speaker hole, it transmits fine.

Receiver sensitivity seems good, even outside the ham bands. The included dual-band duck antenna is something of a compromise, especially on VHF, but the result is certainly adequate. Even so, the NOAA weather station on 162.400 MHz comes in better than it does on my other HT with a single-band antenna. The selectivity is typical of Kenwood rigs, being OK but not real sharp. It can be hard to tell when you're 5 kHz off.

Renaissance Radio

I love high-tech toys and, up until now, I've always felt that the more features, the better. But this rig may finally have gone too far. No question about it, it does everything and then some. In fact, it has features I've never even thought of, some of which are slick and useful, and others which seem pointless to me. Let's look at a few:

You can select which band will be heard when you press the MONITOR button to open the squelch. There are three options: main, sub or both. You can change the sequence of some of the keys, such as the CALL/C SCAN key, so that they perform different functions in different orders. You can select CTCSS independently on each band. In addition to the usual VFO scan limits, you can set VFO tuning limits which will prevent you from tuning the VFO outside them. (Since you are already protected from *transmitting* out of band, I can't imagine why you'd want to do this.) You can select whether or not you want the rig to stay keyed while you manually send DTMF, even if you let go of the PTT. There's even a choice between two beeper sounds for the tone alert function. You can reset the VFO and memories independently to default condition. You can swap the main and subbands, and also select full-duplex crossband operation, listening to one band while you talk on the other! Using this feature, it is even possible to converse telephone-style, continuously transmitting while listening. (You'd better have a big battery and wear gloves, though, because continuous transmitting will drain it fast, and the rig will get quite hot.) You can select from eight scanning modes. And on and on... there seems to be no limit to the hoops you can make this thing jump through.

Strike Up the Bands

Managing two bands at once makes for some interesting control requirements and possibilities. For instance, memory management can be handled in several ways:

You can select a memory between zero and nine with one key press and then rotate the tuning control to get at the other 30. Or, you can split them into VHF and UHF. Or, you can select any memory with two key presses. Finally, there's "page recall," in which you can have it search through four banks of 10 memories each, looking for any memory with the same digit you entered, as long as it's on the same band. So, if you press "4," it will find memory 24 if it is on your selected main band. (If it sounds complicated here, believe me, it is even worse in the manual. But more about that later.)

Tidbits

I noticed several interesting operating characteristics, some of which I couldn't find in the manual. For instance, the output power level setting (HIGH, MEDIUM or LOW) follows the band. Thus, if you set the rig to LOW while transmitting on VHF, and then swap the bands, the output indicator will revert to whatever it was on the other band, and will come back to LOW when you swap back to your original band. It's a nice touch. Too bad the indicator, which is only active for the main band, is shown under the subband's frequency on the display, making it confusing.

The scan speed is medium, being quite a bit faster than that on older rigs, but nowhere near as fast as some other HTs. Also, as on most rigs, the scan stops when the squelch opens, which generally is not on the center frequency of the transmitting station. This, combined with the rig's only fair selectivity, causes the scan to stop three times on each station, with only the second time being on the right frequency. (It also makes the carrier-operated scan stop mode useless for VFO scan, because it will freeze on the wrong frequency and sound distorted.) It is a simple matter to examine the output of the FM detector for DC bias and stop only when it is zeroed in on the right frequency. I wonder why nobody does it; it would be a great improvement.

The S/battery meter displays have 10 steps each but, like the TH-25, they always move in groups of two, so they are really five-step displays.

The radio can be used as a crossband repeater, but not without the modification. Crossband repeat is something people actually use now and then; I wonder why they didn't make it standard.

The battery saver and automatic power off modes can be turned on and off but not adjusted for their time periods. The APO operates after 59 minutes, and there is no mention of the duty cycle of the battery saver. In general, it works well and you should only want to turn it off for packet, DTSS or paging operation.

The tone alert starts a timer which shows

you how long it has been since the call was received.

Making the Complex. . .Complex

The problem is, the presentation of all these wonderful features is truly intimidating. I fully realize that having so much to offer results in some hard choices regarding key press sequences and such, but the interface as well as the key labeling is confusing. For instance, there are the AL, S.CT, M.CT, S.DT, M.DT, C.SEL, U.CHG and UXU keys. Do you really expect to remember what any one of them does? Better mnemonics could have been helped. And the display shows ABC, DUP, DT, CT, TX.S, L, M, R, AL, C, another M and others.

There are various combinations of key presses which seem to make no sense. For instance, to change memory banks, you press the LAMP button along with a digit. Why the LAMP button? And you press the M key and then the MONITOR button (which normally opens the squelch) to enter phone numbers into the DTMF memories. The SCAN key lets you set codes in paging mode. And so on. I know I can't remember sequences such as these, because they have no discernable patterns.

Some rigs have default settings which you select by holding a key while you turn the power on. This rig has *twenty* of them! Most of them are things you won't want to change very often, if at all, but a few can get you into trouble if you forget what they do. And, while some have an indication on the display, some don't. For instance, you can change the delay time before the dual-tone squelch system sends its tones by holding the MHz key and turning the power on. Doing the operation twice causes two different beep tone sequences to sound as the extra delay apparently turns on and off. But nothing shows on the display, so I have no idea what is actually happening, and the manual gives no hint either, because the meaning of the two tones is never discussed.

By the Book

And that brings us to the documentation. Yes, it is fairly complete but, like so many of these booklets, it is written in Jenglish and contains such gems as "use of earphone causes no howling" ("to avoid howling, use an earphone"); and my favorite, "During A.B.C. operation, being exchanging the bands each other" (??? no idea). There are plenty more of these. It's hard enough trying to learn a complicated rig without struggling to decipher incomprehensible language.

I don't mean to suggest that you can't learn to use the rig from this manual; you can. But it is dense reading and will take awhile. To its credit, Kenwood has included a full set of schematics. But the microphone hookup diagram on page 8 of the manual shows a wire with an arrow going nowhere. If you're a technical type, you can probably figure this out from the rest of the diagram. If not, good luck.

A rig this complex and difficult to use needs a wallet-sized "cheat sheet" card. Most new rigs include them, but this one does not.

Tough as this rig is, there is a way you can enjoy it without killing yourself. All you have to do is preset most of the functions once and then memorize only the subset of commands you will use on a daily basis. Apparently, this is what many hams are doing. Here is a report from Greg N4PSA in Miami, who has owned his TH-77A for several months:

"Having purchased the TH-77A in January makes me the local Elmer, so I have been helping folks out with their questions. One overriding complaint from the '77 crowd is about the manual. Actually, all of the functions and features are described, but not clearly.

"During the requisite learning stage of '77 ownership, I saw that the paging function would not work through most of the local repeaters, since they mask transmitted DTMF tones for security purposes. Although some repeaters will pass the tones, they usually must be preceded by sequences which include the # or * to disable the masking function. Unfortunately, the TH-77A does not allow those codes to be sent; it permits only the digits 0–9. This limitation makes the paging feature inoperable in most big cities, where it would be most useful.

"After familiarizing myself with the rig and all of its capabilities, I found that I really only used a small portion of the features. In the end, I left most of the options set up at the factory defaults. It sure would be nice to have a wallet-sized function guide card. I do like the rig, though. It's small, it's light, and when you need to make changes, the flexibility to do so is there. . . but don't lose the manual!" 73 de N4PSA

Get the Bug Spray

Any radio this new and advanced is bound to have a few bugs, and the TH-77A is no exception. Here are some I've found, or heard about and verified:

Kenwood's ads show the upper VHF frequency limit as 165 MHz. Although the radio actually tunes nearly to 174 MHz, the frequency synthesizer won't lock reliably above about 168 MHz. You can tell when it's out of lock because the rig beeps about once per second. The first time it did that, I had no idea what it meant, because it isn't mentioned in the manual.

Several people have reported problems with losing all the memories if they let the battery get low enough to cause the display to flash. Apparently, once it starts flashing, the rig refuses to respond to the power switch, so you can't shut it off. Eventually, the memories get trashed. Naturally, there is an internal lithium battery which is supposed to prevent this sort of thing, but something goes wrong and it doesn't kick in under these circumstances. Greg advises that the cure is simple: If the display flashes and you don't have other power available, remove the antenna (so you won't receive anything) and battery pack, and let the pack sit for about 20 seconds. Then put the battery back on. It should have recovered enough to let you turn the rig off.

There's an option which lets you send either band out to an external speaker while listening to the other band on the internal one. If you select this option but don't plug a speaker or

UNEARTH YOUR FULL POTENTIAL

with the

CHALLENGER DX-VI

A unique multiband vertical that utilizes GAP technology.

The Challenger DX-VI covers all of 2m, 6m, 10m, 12m, 15m, 20m, 40m, and over 130KHz on 80m with a VSWR under 2:1!

It has NO . . .

- TRAPS
- COILS
- BALUNS
- RESISTORS
- TRANSFORMERS
- BASE INSULATORS

The Challenger DX-VI Launches RF from a 16' elevated GAP, not from the base of the antenna. The antenna is PRETUNED. There is nothing to adjust. The Challenger DX-VI has virtually NO earth loss and requires only 3 wires 25' long which attach to the base of the antenna. Thus, eliminating the need for an extensive ground plane. The antenna is 31' tall and is self - supporting with a supplied drop in ground mount. No additional mast is required. Best of all the ENTIRE antenna is active on all bands and costs only $229.00*.

Low-Pass Antenna Tuner

Match your antenna while reducing harmonics with this unique design.

by J. Frank Brumbaugh KB4ZGC

Most commercial and home-brew antenna tuners use essentially the same T-circuit—two variable capacitors in series with the RF, and a tapped or rotary inductor from the junction of both capacitors to ground. Obviously, this circuit works well. It can transform a wide range of impedances to match the nominal 50 ohm output of modern solid-state transceivers over a broad frequency range, from 160 or 80 meters through 10 meters.

However, it also has some disadvantages. It is a high-pass filter configuration and does nothing to reduce the amount of harmonic energy reaching the antenna. Construction is somewhat complicated in that both capacitors must be insulated from the cabinet. Under some impedance matching conditions, the set screws in the control knobs can "bite" your fingers with RF. Also, the cost of high quality variable capacitors and the difficulty of finding them today is discouraging.

There is a simple way of eliminating all these disadvantages while retaining the wide frequency range and impedance matching ability. This circuit is not new—it has been used by a few hams for years—but for some reason it has not received the publicity in ham literature that it deserves.

The Circuit

See Figure 1. This low-pass antenna tuner schematic retains a simple T-configuration. Now, however, the circuit forms a low-pass filter that reduces harmonic energy falling in the television channels by up to 20 dB. Only one variable capacitor is used, and its rotor is grounded, eliminating the possibility of RF biting one's fingers. A center-tapped inductor is in series with the RF, and the center tap is connected to the stator of the shunt-tuning capacitor. Both sections of the series coil are tapped every two turns, and the taps are selected by a pair of rotary wafer switches mounted directly to the grounded panel.

Theory of Operation

Selecting various coil taps with the rotary switches and varying the setting of the variable capacitor, much in the same way the standard tuner is adjusted, changes the operating frequency and impedance transformation ratio. This makes it possible to tune out any reactance, bringing the SWR down to 1:1, keeping the transceiver—and its owner—happy.

Because one tap point on each switch is connected to the center tap of the inductor, it is possible to change the circuit from a T- to an L-circuit with a choice of inductive or capacitive input. This lets you use the tuner with low or high impedance end-fed antennas, including random wires. This feature, impossible to achieve with the standard T-circuit, is handy for Field Day, and could be invaluable in emergency operation with a makeshift antenna.

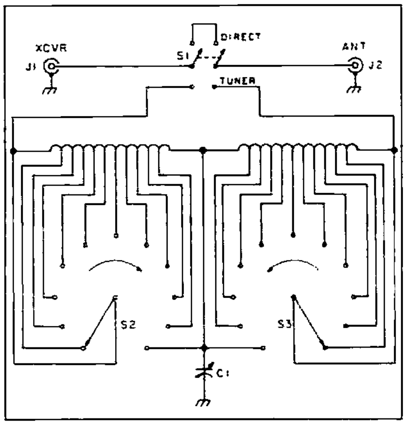

Figure 1. Schematic for the low-pass antenna tuner.

Construction

A shielded metal box or an enclosure made of printed circuit board material should be used. However, this tuner will function equally well "in the open" on a breadboard. Because this unit is designed for the 3–30 MHz range, lead lengths are relatively unimportant.

A single length of air-wound inductor (Barker & Williamson or Airdux) with a total inductance of 35 to 40 µH, or a pair of tapped toroids (T106-2 or equivalent) will work equally well in this circuit. Both coil stock or toroid cores should be chosen with the power level of your rig in mind, of course. I use a Kenwood TS-440S "barefoot," so I chose a "50 watt, 80 meter" plug-in coil of the 5-pin type common in the 1940s and 1950s, which I found at a hamfest for 50¢. It has an inductance of about 17 µH each side of the center tap—34 µH total. It is tapped every two turns.

The shunt-tuning capacitor should have a plate spacing of at least 0.05" for use with the usual 100 watt transceiver. The two wafer switches are ceramic, single pole, 11-position, with shorting contacts. I used a surplus 140 pF tuning capacitor from a BC-610 tuning unit, another hamfest prize purchase. However, a 100 pF capacitor should be sufficient.

The parts layout can be whatever the builder prefers, though the logical arrangement is to mount the wafer switches in a horizontal line on the panel, with the capacitor mounted between them, or slightly above or below the wafer switches.

A miniature DPDT toggle switch, rated 6 amperes at 120 VAC, is included for ease in inserting or bypassing the tuner in the transmission line. This is not required, but it eliminates unscrewing and rescrewing a lot of coaxial jumper cables when changing from using the tuner to feeding the transmission line directly.

Finding the Parts

Check out your junk box. Ask local hams and at your next ham club meeting. Scrounge the flea markets at hamfests. These are the cheapest ways of getting the coil and capacitor.

If all else fails, suitable air-wound inductors are available from *Surplus Sales of Nebraska, 1315 Jones, Omaha NE 68102.* Suitable variable capacitors are available from *Fair Radio Sales, P.O. Box 1105, Lima OH 45802.* Radio Shack and numerous mail order electronic parts dealers can supply a metal enclosure, knobs, wafer switches and RF connectors. *Radiokit, P.O. Box 973, Pelham NH 03076 (603) 635-2235* is another good source of wafer switches, coils (B & W Airdux series) and large variable capacitors. The capacitor plate spacing and the size of the coil will depend on the amount of power you wish to run through the tuner. For example: If you are running under 100 watts try using Radiokit coil # 1606T or 1608T (2" diameter B & W Airdux) and variable capacitor #21140 (Millen) or #149-6-1 (Cardwell).

Parts List

C1	100 to 150 pF variable capacitor, 0.05" spacing.
J1, J2	SO-239 or other RF connector.
L1	35-40 µH coil, center-tapped.
S1	DPDT toggle switch.
S2, S3	Single pole, 11-position ceramic wafer switch, shorting contacts.

Operation

Connect the low-pass antenna tuner between the antenna transmission line and an SWR meter which is connected to the output of your transceiver. Set C1 to half

Continued on page 73

Continued from page 45

earphone in, the "external" band does not revert back to the internal speaker. It just disappears! The rig was set to this mode when I got it and I thought one band was broken. It took me quite awhile to unravel the mystery.

Suggestions

The SHIFT/REVERSE button should have its functions exchanged, so that reverse could be selected with one key press. You don't change the shifts all that often anyway, so it would be fine for them to require use of the FUNCTION key.

I doubt the "one-upmanship" trend of cramming more and more digital features into walkies is going to go away, but they can be made easier to use. A rig this versatile could use a better display system.

The next logical step is a dot-matrix, scrollable menu display like those found on pocket computers. That, along with a better-organized control sequence, would go a long way toward making a nifty radio like this one a joy to operate. At the very least, a "set" mode, in which all the rarely-changed default settings are grouped, would be useful.

Conclusion

All in all, this is the slickest dual-bander I have yet used. It feels good, works well, and has more features than I will ever need. This is a premium rig for those desiring the utmost in versatility. If you're in the market for a dual-bander, check it out. With an improved user interface, it could be close to ideal for everybody. ■

Sacred Heart Amateur Radio Club

In April 1991, I had the pleasure of meeting in person with Dave Novak NØDN at the Dayton Hamvention. He and his students had checked into the CO All Schools Net several times, and we had exchanged interesting tapes, pictures, and letters between our two groups. Our meeting at the Hamvention convinced me that the work of Dave and his amateur radio club students could serve as a wonderful inspiration to other instructors. The following is Dave's write-up about how he organized this exciting program for young people.

De Dave Novak NØDN

I have been licensed since I was in 7th grade. My primary mentor was my dad, Joe Novak WØPGI. As a teacher and youth minister, I began working with junior high students about 14 years ago. My work with them in technical areas began when I was at a school that had a variety show for students, parents, and friends. I began training students in taking still photos, taping videos, and operating sound and lighting equipment. At the next school, I formed a club called the "Media Club," which got the youth involved in computers as well as photography.

Being a "teenage" (ordained 13 years ago!) diocesan priest, I get moved around every few years by the bishop, and I've formed clubs at each school. However, I never did try to interest kids in amateur radio. I believed up until recently that it would be too hard for junior high kids to learn Morse code, and that it would be too expensive a hobby for the general public. I thought to myself: "It is different if a parent is a ham and one of the children get interested, but 'normal' parents just wouldn't understand!"

To be quite honest, my own interest in the hobby had begun to wane. Although at every new assignment I did manage to get antennas up, I often went for weeks without getting on the air. Months would go by without my going to any ham club meetings or hamfests.

With the Help of an Earthquake

Then while at the rectory on the night of the big earthquake in the Bay area, my phone began to ring. Three people called and asked if I could find out about their loved ones. To my surprise, after only a couple of hours on the air I was able to find out that all three parties were alive and well. Perhaps for the first time in my long amateur career (30 years this fall!), I began to realize what a vital service our hobby can provide. I think that night was a turning point for me. Shortly after that, I began getting on the air more frequently and going to ham club meetings, breakfasts, and hamfests.

Soon after that, I was moved to my present QTH. Since it was in the middle of winter, I only put up a temporary antenna. Then in the spring, I put up the tower.

While the maintenance man, Ed Gilmore, helped me level the newly poured cement for the tower, some students passed by and wanted to put their initials in the wet cement. I encouraged them! Over 100 kids wrote their initials, a couple made hand prints, and one girl made an impression of her foot.

The next week I set up a station in one of the classrooms, and arranged for each class (grades 5 through 8) to come in for a demonstration. I printed up a flyer with photos of myself as a young ham. The flyer stated that there would be a "ham radio camp" during the summer. No 8th graders signed up. No 7th graders signed up. No 6th graders, either! Only one 5th grade boy and two 5th grade girls expressed an interest.

At first I was quite disappointed. But I thought: "I didn't get my license till I was in the 7th grade, even with my dad being a ham. How can these 5th graders possibly get their licenses? What the heck—I'll give it a try!"

Photo A. KBØHWN checking into the All Schools Net during her lunch period.

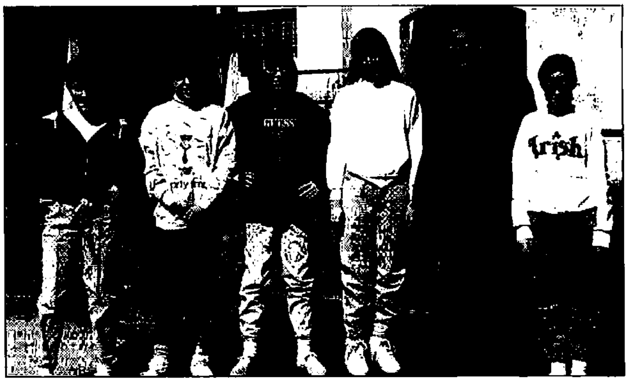

Photo B. (Left to right:) Jenny Ebert KBØIYT, Vanessa Gomez KBØIXY, Amy Rosa KBØIRI, Angie Fischer KBØHXY, Dave Novak NØDN, and Mary Ellen Federhofer KBØHWN.

I began by getting them *Tune in the World* kits, and encouraged them to listen to the code tapes. When the camp actually began in July, two more boys showed up. I solicited the help of a ham friend of mine who was free during the day, and also the help of two teenage hams. We met Monday, Wednesday, and Friday from 9 a.m. till noon for two weeks. During this time we studied rules and theory, practiced code, and built code oscillators. Also, one morning we took a "field trip" to visit another local ham. By the end of camp, 4 out of 5 students passed the written test, but none were able to copy the 5 wpm code.

More Students Join the Club

In September, to my surprise, the kids wanted to meet weekly, and some of their friends wanted to join. This presented a challenge, since the original group was so close to getting their Novice while the rest had only good intentions! Then I discovered a retired telephone company engineer, Steve Gies WØKOC, and was able at times to break the group up into two. Also, I found the young almost-hams willing to help their friends out.

Because 5 wpm seems so difficult for someone just learning code, we worked out a special incentive program. There were special prizes for just being able to recognize the alphabet, for receiving at 3 wpm, and for receiving at 4 wpm. Since many of the prizes had something to do with the local ice cream parlor down the street, it became a regular routine of our Wednesday after-school gatherings.

In October, we received a 10 meter transceiver from Uniden, which we set up in the classroom but also allowed kids to borrow and take home after school. I kept the microphone at school so there would not be any temptations too great to resist!

By Christmas, each of the five original members received their Novice licenses: Mary Ellen Federhofer KBØHWN, Angie Fischer KBØHXY, Tom Winkler KBØIBA, Matt Kirchhoff KBØICV, and Patrick Scheu KBØIDH. In fact, Angie received her license on Christmas Eve, and came to church service about an hour early so she could make her first contact. The next day, she had an antenna up in her own back yard. Mary Ellen had received her license just a week or so before, and was also on the air with borrowed equipment.

My original idea was to rely mainly on the school station for the kids to operate. But once I saw the thrill of the kids having a station set up in their own home, I began to look for ways to acquire additional equipment.

Although I knew that we could raise money quickly by selling chocolate bars, I wanted to do something that would bring the group together, and allow the children to use their talents and creativity. The idea of a "dinner theater" came to mind. I knew that some of the girls had already written a skit about dating. I suggested that they write their own rap about ham radio and call themselves "The Code Girls." To my surprise they accomplished this in a few days.

There were some difficult afternoons shortly before the big night when things did not go well! It was only a week away, and some of the kids did not yet remember all of their lines. But somehow when the big day came, the kids did great and everyone had a great time. One of the mothers, Shellie Kirchhoff, was able to fix pasta and salad for over 150 people for only $140! Even though we charged only $5 per person, we ended up making over $700, which included donations from folks who could not come, but sent in $5 or $10 to help out the kids.

Most of the money I had already spent, having just come back from Florida with a station wagon full of radio gear that I had bargained for in Memphis and Indiana as well as Florida. We have about five used radios we have purchased—the best being a Drake TR-3 which we paid only $150 for, and which performed well just as we received it. Some of the other gear that's not working is being restored by Cathy Barne's dad, Wayne Barnes, who repaired radios when he was in the Service.

More Accomplishments

Since the dinner theater, several others have passed their Novice exams: Julie Thien KBØIRH, Amy Rosa KBØIRI, Sean Sitek, Vanessa Gomez,

Photo C. Patrick Scheu KB0IDH (left) and Tom Winkler KB0IBA (right) on low band "ground wave" operation.

Jenny Petersmeyer, and Jenny Ebert. I feel confident that three other members will soon pass their Novice exams: Mark Moore, Cathy Barnes, and Jason Roskowski. The same day Sammy AA0CR received the Westlink Young Ham of the Year Award, we had our first upgrade: Angie Fischer, who passed the Technician exam.

Yesterday I fixed lunch for some of my adult local ham friends, and also arranged for some of our new school hams to join us. After dinner, they performed "Morse Code Baby" then introduced a spontaneous routine. Once they perfect this, we'll make a video of it! (Watch out, East Coast and West Coast! The Code Girls will soon be taking over the U.S.A. by storm and invading everywhere! No classroom within the continental U.S. and maybe beyond will be safe any more entrenched in a pre-technical subculture deprived of their right to the exciting new world of ham radio!)

This week, we are working on plans for a new "Summer Ham Camp" especially for junior high kids. I am meeting with Sammy AA0CR, who has volunteered to help. Most likely we are going to try to acquire a central location where young hams from all over the metro area will be able to participate. We have a lot of work ahead of us, but with almost unlimited enthusiasm and spirit to drive us on! 73

Please send write-ups on interesting classes, recruiting ideas, youth club activities, or individual children's experiences along with photos, to Carole Perry at the above address.

Fluxgate Magnetometer

GENERAL:
The first low-cost portable hand-held fluxgate magnetometer with laboratory accuracy. For magnetic measurement from 1 gamma (0.01 milligauss) to 2 gauss with an absolute accuracy of ± 0.5% traceable to NIST (previously NBS). Analog output DC to 100 Hz.

TYPICAL APPLICATIONS:
Earth's field vector measurements, air shipment inspection, mapping and recording field perturbations, etc.

73 Review

by Bill Clarke WA4BLC

The Drake R8 Receiver

R.L. Drake Company
540 Richard Street
Miamisburg OH 45342
Price Class: $979.
Tel. (513) 866-2421.

Tune in the world with this hot new receiver.

A Drake, a real Drake! The folks from Miamisburg have finally produced a new product for the radio hobby market—a high grade communications receiver aimed at the lucrative and popular SWL market.

Before I started this review I looked back into radio history and found that from about 1979, the Drake R7 communications receiver was the last available Drake HF receiver. The last piece of HF ham equipment from Miamisburg was the TR7 from 1978, from which the R7 got its general appearance and features.

Prior to the R7, Drake communications receivers included the DSR1 (1971) and the DSR2 (1974). One of their most popular receivers was the SPR-4 from the early 1970s. All solid state and featuring a linear PTO and vernier dial providing 1 kHz readout. So much for history; let's look at this new release from Drake.

Appearance

The R8 has a very functional, businesslike look, sporting few manual controls, and a black finish. The lack of radio-like appearance is due to the heavy reliance on state-of-the-art digital control. There are only six standard analog controls on the unit, as nearly every possible selection that can be made by switching is accomplished via the dual-purpose keypad or a function switch.

First Impressions

The most apparent feature of the R8 is the very complete LCD display. Measuring 5.5" x 1.5", it displays all functions and settings in bright characters on a black background, making status checking super easy.

The layout of the function buttons places them directly beneath their corresponding readout points, making selections of AGC, bandwidth, mode, etc., very easy to use as well.

Frequency control is via direct entry on the keypad, with the UP/DOWN buttons (in 100 kHz steps), or a TUNING knob (with a choice of tuning speeds). The frequency reads out to 10 Hz (user selection). When put on a frequency, the rig can be locked and it will remain there indefinitely. It's very stable. There are two VFOs which you can select instantly via function switch, and 100 nonvolatile memories. This means no batteries are required for memory backup; power interruptions will not erase the memory.

Scan features allow scanning of all memories, selected memories, or the frequencies between the settings of VFO-A and VFO-B. The SQUELCH control greatly enhances the use of SCAN, and is active in all modes.

Bandwidth from 6 kHz to 500 Hz can be selected in all modes. This is a very good feature for crowded band conditions, and for fidelity during better times. After all, AM does sound better at 6 kHz wide than at 1.8 kHz. But each bandwidth has its place and use.

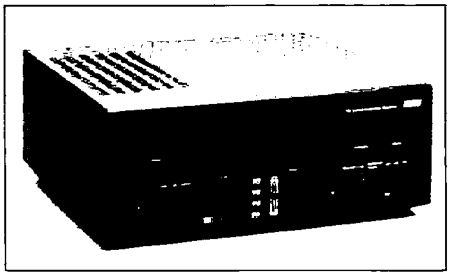

Photo A. R.L. Drake's new R8 receiver for SWLing.

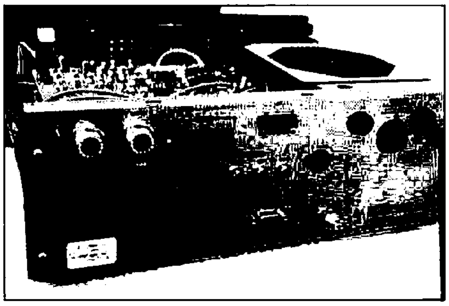

Photo B. The R8 can be connected to various antennas as well as to a computer through the RS-232 port.

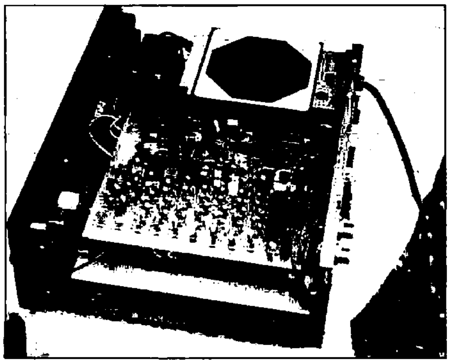

Photo C. This inside view of the R8 reveals just how neat and sturdy it is!

The controllable AGC, NOTCH FILTER (manually operated from an analog control), NOISE BLANKER, and RF input controls (analog and switched attenuator/preamp) all combine to make the receiver very flexible.

Unlike ham equipment, the R8 has a built-in clock/timer with an output port on the rear for remote control of a tape recorder (or other hardware). This time feature is very popular with SWLs for recording odd-hour programs, and it can also be used in a clock-alarm-radio scheme (though a very expensive clock-radio). The clock also displays time on the LCD when the unit is powered off.

The fold-down front feet make table placement and viewing of the LCD display and S-meter clear and easy.

In many ways, the R8's control and display system is not far from that of a modern, full-featured 2 meter HT. Loads of bells and whistles provide extensive flexibility.

The manual that comes with the R8 is very well done, with complete explanations about each feature and control. A section is included that delves well into computer command of the digital switching system, and a log is included to write down the pertinent information about what is entered in each of those one hundred memories. It is, however, without block and schematic diagrams.

Operating the R8

The R8 was tested on a 160 meter Carolina Windom antenna (about 265 feet long) at 50 feet, and also on a 40/75 meter dipole at 35 feet. It was compared, via an A/B switch system, with an ICOM R71A. I selected the R71A due to its excellent reputation as a "world SWL standard."

The tunability and stability of the R8 are excellent; however, although the tuning knob has a good weight, it's a little small for my taste.

I am a real believer in keypad frequency entry. It is quick and accurate. The rubberized keypad is easy and flawless to operate.

When in the AM mode, I found the SYNCHRO (synchronous detector) to be great when fade-caused distortion became a problem. This is a feature that really works.

	Specifications
Frequency Range	0.1–30 MHz
Modes	AM, LSB, USB, CW, RTTY, FM
Sensitivity	SSB & CW (10 dB S+N/N)
	<1 µV (0.1–1.5 MHz)
	<0.5 µV (1.5–30 MHz)
	<0.25 µV (5.0–30 MHz) preamp on
	AM (10 dB S+N/N)
	<3 µV (0.1–1.5 MHz)
	<1.5 µV (1.5–30 MHz)
	<.8 µV (5.0–30 MHz) preamp on
	FM (12 dB SINAD)
	<.5 µV (1.5–30 MHz)
Frequency Stability	< ±10 ppm (-10°–50°C)
Frequency Accuracy	< ±100 Hz (-10°–50 °C)
Selectivity	AM, LSB, USB, RTTY, CW
	6 kHz @ -6 dB–<12 kHz @ -60 dB
	4 kHz @ -6 dB–<8 kHz @ -60 dB
	2.3 kHz @ -6 dB–<4.5 kHz @ -60 dB
	1.8 kHz @ -6 dB–<3.6 kHz @ -60 dB
	500 Hz @ -6 dB - 1.5 kHz @ -60 dB
	FM
	12 kHz @ -6 dB - <25 kHz @ -60 dB
Ultimate Selectivity	>95 dB
Image Rejection	>60 dB (100 kHz–1.5 MHz
	>80 dB (1.5–30 MHz)
IF Rejection	>80 dB (45 MHz)
	>100 dB (50 kHz)
Dynamic Range	>90 dB (1.5 - 30 MHz @ 20 kHz spacing)
3rd Order Intercept Point	> +5 dBm @ 20 kHz spacing
	>-20 dBm @ 5 kHz spacing
IFs	First 45 MHz;
	Second 50 kHz
AGC	Attack time 1 ms
	Release 2 sec (SLOW)–300 ms (FAST)
Antenna Input	50/500 ohms
Notch Filter	Audio Type >40 dB depth (500–5000 Hz)
Audio Output	2.5W @4 ohms with <10% distortion
Recorder Output	300 mV @4.7k ohms
Demod Output	300 mV @ 4.7k ohms
Clock Accuracy	< ±2 sec/month
Power Requirements	100/120/200/240 VAC (60 Hz) @40W
	11–16 VDC @2 amps
Size	13.1"W x 5.2"D x 13"D
Weight	13 lbs.
Accessories	•VHF converter 35–55 and 108–174 MHz
	•Matching external speaker
	•Software package for the IBM XT/AT (clones) to allow enhanced operation of the R8

The NOTCH filter, although effective, was disappointing in depth and in its analog operation. I cannot understand why any manufacturers produce receivers with manually operated notch controls today. My Datong ANF (Automatic Notch Control) knocked out tones the R8 could not—and with no manual control input!

The PASSBAND OFFSET was, as expected, effective in removing interference from nearby signals. Selecting a narrow bandwidth made it all the more effective.

I was not impressed by the internal speaker with its typically poor fidelity. An external speaker is a must for real enjoyment.

The S-meter read as expected, and compared in accuracy to other receivers.

The tone control lacks real BASS/TREBLE authority.

The R8 is a natural for computer control, since all controls, except for those in analog form, can be commanded via the RS-232 port. Command information about computer interfacing is given in the manual (this section is very good). Suggested software for computer control includes PROCOMM PLUS™ and BITCOMM™ operated on an IBM XT/AT or clone. Optional software is available from Drake for use with the R8 (not available for this evaluation).

On a warm summer evening when the popcorn (static caused by distant thunderstorms) was popping heavily, I listened to my regular nets with the R8. The R8 held its own very well, being less affected by the static than my ICOM IC-751A transceiver. It was not as quiet as the Ten-Tec Corsair II, but then, these pieces of equipment are of a very different design and purpose.

The choice of bandwidth made it fairly easy to reduce nearby signals, such as those that abound on 75 and 40 meters. Add the passband filtering, and you can just about eliminate any adjacent signals as much as is possible.

Speaking of bandwidth, you should hear what a real strong LSB signal on 75 sounds like through the 6 kHz filter. Just like broadcast AM! Too bad I couldn't locate the mike plug on the R8.

A Few Comments

After carefully evaluating the Drake R8 receiver, I must say that I am well pleased with its performance. Over the years more than a few pieces of Drake equipment have passed through my shack, and I still think you have to go a very long way to beat the receivers of the R4 series. They were quiet, stable, selective, and sensitive. The R8 compares favorably with these older receivers, as few digital-type receivers can.

Modern digitally-controlled receivers make lots of internally manufactured noise—noise that adversely affects their operation. The Drake R8 does not suffer appreciably from this problem.

The R8 is like a breath of fresh air, with its ground-up engineering and up-to-date digital control from the front panel. I am very pleased to see a quality HF receiver of American manufacture that should successfully compete on the world market.

Oh yes, a public question for Drake: Where is the T8 transmitter to go with the R8? The world is waiting! 73

P.O. Box 2508
Fullerton CA 92633

Build the TBOX

At last, you won your club's competitive RDF contest ("foxhunt" or "T-hunt"). Now it's your turn to hide the transmitter. You've driven for hours to pick the perfect hard-to-find spot, but now you need some distinctive audio to transmit, and a way to ID the hidden "T."

You could stay with your rig and talk throughout the hunt. But that's hard on your throat and gets boring after a while. Besides, if hunters spot you, they'll know where the "T" is. It's lots more fun to conceal the fox, perhaps even bury it! Then you can stay under cover nearby and watch the fun as the hunters approach and try to "sniff" it out.

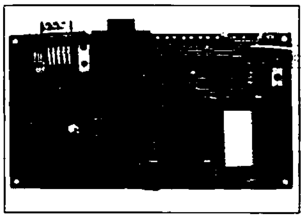

Photo A. Prototype TBOX circuit on N6MBR's PC board.

What you need is a "tone box" or "foxbox." A good one produces a distinctive sound, so the hunters have no doubt that they're tracking down the right signal. It cycles the transmitter on and off periodically for intermittent-signal hunts.

A foxbox must incorporate station identification, to comply with FCC rules. The callsign should be easily changeable, to accommodate upgrades and permit the box to be used by all members of a hunting group. Small size and low battery drain are important design objectives.

Micro-P Solution

Several good discrete-logic circuits for tone boxes have circulated among T-hunters over the years. But for the utmost versatility, a microprocessor is ideal.

Ron Seese N6MBR is an active T-hunter with the Conejo Valley Amateur Radio Club, based in Thousand Oaks, California. He is also a clever digital designer and has developed a multi-featured foxbox designed around the 80C31 CMOS microprocessor. He calls it TBOX—a box to control the hidden T. It meets all the above requirements, yet it contains only six ICs and a few discrete components.

TBOX provides a readily-identifiable tone pattern for the hidden transmitter audio. Or, if you prefer, it sends randomly-pitched beeps. Transmission can be continuous, with regular CW identification.

For intermittent-signal hunts, it automatically turns the transmitter on and off at regular intervals, with CW ID on each transmission. You can select on and off times over a wide range. To save your batteries, TBOX draws only 60 mA at 12 VDC.

TBOX programming does not require a myriad of switch settings. In fact, there is only one switch on the unit—the power switch! To set the TBOX parameters (such as mode, callsign, CW speed, and on/off timing), just hook the RS-232 cable to your computer, load your modem program, and use TBOX's programmed-in menu structure. It's much like setting the parameters on your packet TNC.

A battery-operated computer with RS-232 port is perfect for programming your TBOX. If you don't have one, it doesn't matter. You can program it with your home computer (my old Kaypro works just fine) or even a dumb terminal.

TBOX includes a non-volatile memory (EEPROM) that remembers your hunt parameters. After programming, disconnect TBOX and take it to the hiding spot. When you turn it on in the field, it will come up just as you programmed it.

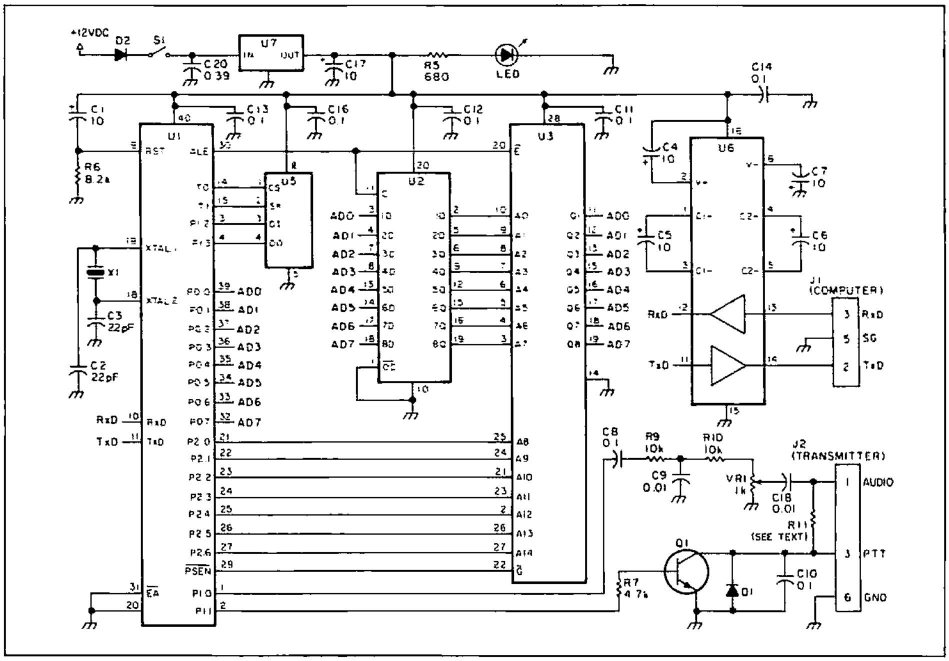

Figure 1. TBOX schematic diagram. All capacitances are in microfarads, except C2 and C3.

How It Works

Figure 1 is the complete TBOX schematic diagram. CPU chip U1 executes the program of EPROM U3. U1 contains 128 bytes of dynamic RAM built in. R6 and C1 reset U1 at power turn-on to ensure proper startup. EEPROM U5 holds the callsign and other configuration data during power interruptions. RS-232 interface chip U6 links the unit to your computer via J1 for parameter setting.

J2 connects TBOX to your hidden transmitter. Q1 and associated components close the radio's push-to-talk (PTT) circuit. C8, C9, C18, R9, and R10 buffer the transmit audio. Potentiometer VR1 sets proper modulation level.

R11 combines the PTT and audio lines to drive hand-held rigs. For ICOM HTs, use a 3.9k resistor at R11, and hook only the AUDIO output line to the HT's mike input. The same connection works for Yaesu HTs, except that R11 is 2.2k. For non-hand-held transmitters, delete R11 and connect the separate PTT and AUDIO OUT lines to the appropriate pins on a mike plug to mate with your rig.

Let's Build It

If you enjoy wire-wrap assembly, you will have no trouble duplicating Ron's circuit from Figure 1. Be sure to put capacitors C11–C14 and C16 as close as possible to the appropriate ICs to prevent unwanted oscillation and interaction. I suggest socketing all ICs except the +5V regulator. Be sure to use a socket at U3 to permit program upgrading.

If you have access to a "PROM burner," you can program U3 yourself. The latest BIOS program (version 0.7 as of this writing) is available on the 73 BBS at (603) 525-4438. Hams on the West Coast can find it on the NOMAD PCBoard BBS at (805) 498-3500. File names are TBOX07.BIN and TBOX07.DOC.

If you're like me, you would prefer a PC board, and would rather have someone else do the work of making the board and programming the BIOS PROM. Fortunately, N6MBR has done it. Send Ron a check for 35 dollars and ask for the "Homing In" TBOX package. He will mail you a blank 3.25" x 6" double-sided circuit board (see Photo A) and a programmed PROM. He will also throw in one of the hard-to-find EEPROMs for U5.

Of course neither I nor *73 Amateur Radio Today* can warrant this offer. But I can assure you that the six boards used at this spring's Friendship Radio Games foxhunt worked flawlessly. The board is high quality, with plated-through holes. Parts layout details are included.

The ICs in N6MBR's board are so close together that some sockets may not fit. I used pin-line socket strips instead. These are solder-tail socket contacts that come in rows of 25 to 40. Just break off as many as you need for each row of each DIP and solder them onto the board. They are small enough to allow ICs to be side by side only 0.1 inch apart.

Note on the schematic that certain part designators, such as U4, are not used. Also, there are holes and etch for

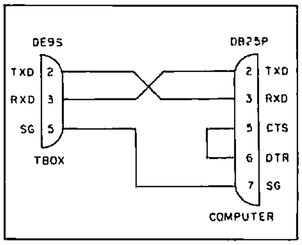

Figure 2. Typical cable connections for computers/terminals with DB-25 RS-232 ports.

Parts List

U1	80C31	CPU
U2	74HCT373	latch
U3	27C256	EPROM
U5	93C46	EEPROM
U6	MAX232	RS-232 interface
U7	7805CTH	voltage regulator
Q1	2N2222A	transistor
D1	1N914	diode
D2	1N4001	diode
X1	12.0 MHz	crystal
J1	DB9PRA	male connector
J2	DB9SRA	female connector

Sources of Parts: ICs, connectors, crystal: JDR Micro Devices, 2233 Branham Lane, San Jose CA 95124. Tel. (800) 538-5000. **PC board, PROM, EEPROM:** Ron Seese N6MBR, 6136 Landino Dr., Westlake Village CA 91362.

additional parts on the printed circuit board. Those parts are not needed for this version of TBOX. Ron is working on new features that use them. I'll have more on that next month.

Capacitor C20 is essential to prevent U7 oscillation when supply leads are long. There are no holes for C20 on the PC board, so "airline" the part on the back of the board.

Firing It Up

Carefully inspect your work after assembly. Pay special attention to polarity of the electrolytic capacitors, particularly those on U6. Check for shorts on the +5V line before installing the ICs.

Install U7 first, then power up the unit and check the +5V bus. If everything is OK, remove power and install the remaining ICs. Now hook up the computer and transmitter interfaces.

Figure 2 shows wiring of a typical cable to connect TBOX to a standard DB-25 RS-232 port. TBOX is configured as Data Terminal Equipment (DTE). This means that TXD on TBOX goes to RXD on the computer, and RXD on TBOX goes to TXD at the computer.

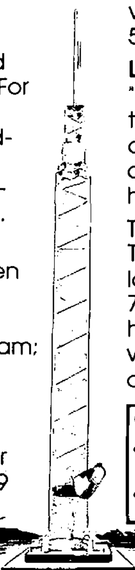
Your computer or terminal program may require a high signal on the DCD line (pin 8 of DB-25). If so, add a jumper from pin 6 to pin 8.

Software and hardware handshaking is not used. Flow control in your terminal program is not necessary, so turn it off. Set the computer to 2400 bps, 8 data bits, and no parity.

Put a dummy load on the transmitter and listen to the TBOX signal on a separate receiver. At power up, TBOX outputs the menu to the computer, then goes into transmit mode. Press the return key on the terminal to stop transmitting, and enter the command mode. When setting parameters, simply enter three digits. For example, to set Mode 2, type "M" and then type "002" without a carriage return.

Your turn to hide the fox may come sooner than you expect, so get started on your TBOX now. Next month, I'll have more on programming and using your tone box. 73

NOW YOU CAN AFFORD THE BEST!



Engineered for the Ham, The Finest in Crank-Up, Free-Standing or Guyed Towers from Tri-Ex. For over 30 years, the INDUSTRY standard-backed up with Defense and Aerospace technology.

MW SERIES
Self-supporting when attached at first section—will hold normal Tri-Band beam; 25', 33', 50', and 65' heights.

W SERIES
Aerodynamic tower designed to hold 9 square feet in a 50 MPH wind. 3 models at 36', 51', and 67' heights.

LM SERIES
"W" brace motorized tower. Holds large antenna loads. Models at 37', 54', and 70' heights.

TM SERIES
Tubular construction for larger antenna loads at 70', 90', and 100' heights. Free standing, with motorized operation.

Have a BLT for Launch

After watching videos and demonstrations of other balloon experiments, members of the Houston AMSAT group decided to put together their own launch effort. Dubbed the BLT (for Balloon Launch Team), they decided to build an inexpensive 2m FM telemetry package for their first flight.

This first package (BLT-1) carried a 100 mW 2m FM transmitter (see the August 1990 issue of *73*) which sent out an audio telemetry sequence. A custom designed analog telemetry system sent out a series of tones seperated with a CW message. The pitch of the tones determined pressure, and inside and outside temperature. The altitude was determined with a pressure sensor circuit designed by John Fleischer of the Transolve Corporation (the circuit appeared in the October 1990 issue of *Radio-Electronics*). The original design was meant to be used up to 20,000 feet on model rockets, but the BLT group used just the analog portion and recalibrated it to operate up to over 100,000 feet. Since the package didn't generate a lot of heat, Andy WA5ZIB included a chemical heat pack to keep things warm during the flight.

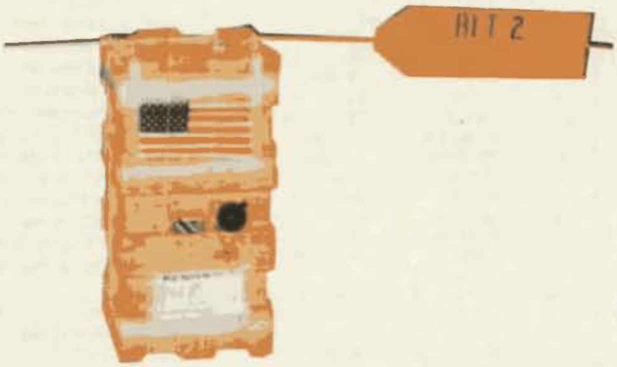

Photo C. The second (and third) BLT payload. The weathervane helped maintain stability during the flight. Note the Radio Shack beeper which helped the chase team to hear the downed payload. The TV camera/mirror is on the other side of the payload.

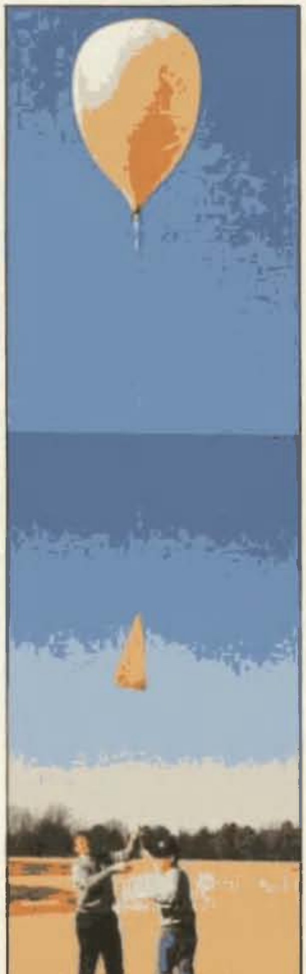

Photo A. Burns Cleland WB5HLZ (left) and Allan Fox N5LKJ (right) prepare to launch a BLT special to the edge of space.

Photo B. Andy MacAllister WA5ZIB puts the finishing touches on the first BLT experiment.

On December 8, 1990 the BLT group sent their first payload up from the Huntsville Texas Municipal Airport. After a great flight up to over 100,000 feet, the package parachuted down to land about 30 miles to the south near the town of Magnolia. Reception of the telemetry signal was observed over a wide area of Texas and Louisiana.

Recovery Texas Style

After a long search, the chase crew eventually pinned down the landing site about a mile or two off of the main highway. Things were going well until they asked the ranch owner if they could search for their package. He replied, "NO, come back tomorrow!" Nothing more frustrating than hearing your payload crying out for help and not being able to do anything about it.

The dejected tracking crew almost decided to risk their lives and go in anyways but thought better of it. A couple of trackers returned the next day and to their amazement the payload was still transmitting! The landowner took them back through several locked gates as they closed in on the package. It turned out the payload had parachuted down in the middle of a large private (and heavily patrolled) hunting preserve! After a short search they found the payload hanging about 80 feet up in a tree.

One of their escorts disappeared for a few minutes and returned with his rifle. With just a few shots, he cut the string (90 feet away) and brought the payload tumbling down out of the tree. Everyone was thankful they had the foresight not to trespass the night before!

BLT-2

With the success of their first flight, the South Texas Balloon Launch Team embarked on a much more ambitious effort. This payload contained an ATV transmitter with a live TV camera (GBC CCD-100), active mirror control (to point periodically at the horizon or the ground), digital voice ID on the video subcarrier (the messages changed with various stages of the flight—one of them actually said, "I'm falling" during the parachute descent), a CW HF

Photo D. The chase team recovers the first BLT payload nearly 30 hours after launch...and it's still ticking! L to R: Mike WA5TWT, Mike N5QMG, Burns WB5HLZ, and James N5PRQ

beacon on 10m, and 2m FM telemetry that even included a packet telemetry downlink from the onboard flight computer.

The flight computer took the analog telemetry signals and converted them to ASCII text for the packet and CW downlink. It also controlled the TV camera mirror. During ascent, the computer would cycle the mirror to point at the ground or the horizon every 50 seconds. During the parachute ride back to earth, the mirror stayed in the down position to look for distinguishing landmarks on the ground.

Crash!

BLT-2 was launched from the Wharton Texas Municipal airport on the morning of May 11, 1991. Due to 10 mph winds, the balloon crashed into the side of a hangar just seconds after liftoff! The 10m CW beacon transmitter (a 28.322 MHz Fireball transmitter built by Bob Moody K7IRK—see the November 1990 issue of *73*) was ripped off the package along with the ATV antenna. The flight computer reset to a dormant mode and the stabilization fin fluttered back to the ground. The balloon and what was left of BLT-2 headed skyward (fortunately the 2m beacon still worked). Spirits were definitely not as high as the balloon at this point. Fortunately the balloon burst prematurely at 27,000 feet (probably due to the crash). The direction-finding crew went into action and quickly found the package 12 miles away in a field near Egypt (Texas). It was noon, so the crew dusted off the payload, reset the computer, glued the ATV antenna back on, and re-attached the 10m beacon. It was time to try again.

Two Flights in One Day

The hastily refurbished BLT-3 was ready to fly. This time the launch team carefully choreographed the release sequence which resulted in a beautiful takeoff (no crashes this time).

Fantastic live camera images from the payload delighted everyone watching the ATV receiver at the launch site. Telemetry from the packet downlink was displayed on laptop computers at mission control as well as by the chase crew. Those without packet stations had a blast decoding the CW telemetry. The ATV signal was received as far away as Dallas (over 250 miles) and the 2m FM telemetry could be heard on HTs at that distance as well. The 50 milliwatt 10 Fireball beacon was even heard 500 miles away (groundwave) by Warren W5DFU in Tulsa, Oklahoma.

This time the balloon landed 18 miles to the north in a hayfield near Wallis. The now-experienced chase team found the payload in short order. A lot of fun and adventure was had by all. Look for future flights from the South Texas BLT. ■

HIGH PERFORMANCE PRESELECTOR-PREAMP

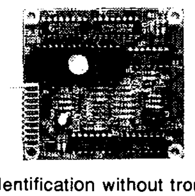
The solution to most interference, intermod, and desense problems in repeater systems.

- 40 to 1000 Mhz tuned to your frequency
- 5 large helical resonators
- Very high rejection
- Low noise—high overload resistance
- 8 db gain—ultimate rejection >80 db
- GaAs fet option (above 200 Mhz)
- Cast aluminum enclosure
- N, BNC, and SO239 connector options

Typical rejection:
±600Khz @ 145 Mhz: 28db
±1.6 Mhz @ 220 Mhz: 40db (44db GaAs) ±20 Mhz @ 800 Mhz: 65db
± 5 Mhz @ 450 Mhz: 50db (60db GaAs) ±20 Mhz @ 950 Mhz: 70db

AUTOMATIC IDENTIFIERS

- Up to 8 EPROM programmed messages
- Adjustable audio, speed & interval timer
- "ID over voice inhibit"
- Low power option
- Modular design
- Message selection via binary input—TTL levels
- Size: 2.7 x 2.6 x 0.7"



NEW Model ID-2B

The ID-2B provides required station identification without troublesome diode programming. The "ID over voice inhibit" circuitry allows for courteous operation by not allowing an ID until the next squelch closing.

ID-2B Wired/Tested $99.95 **ID-2B-LP Low Power $109.95**

Notes from FN42

Lots of news this month, and promises of more to come: Zafizis Tzobakas SV2AHT will report on the mountain climbers of Greece, who made another trip to the high country with an expedition to Pamir of the Himalayas last July. Jonas Paskauskas LY2ZZ will provide us with the results of the Ham Conference that took place in June. And we have another volunteer Hambassador, Ed Sershon DL/N7PHY. He and his wife have moved to Germany from Seattle, Washington, USA and expect to be there for many years. If you have information for him, send it to Ed Sershon, Ferdinand Thomas Weg 6, 3389 Braunlage, Germany.

Skip Westrich WB8OWM wrote us a nice letter to let us know how much he enjoyed the article about "Box 88 Moscow." He also wrote to Ron Gang 4X1MK, who had submitted the article compiled by Oded 4X4SO. Thank you, Skip. We appreciate feedback from our readers. Those of you who have special wishes as to what you would like to see in this column from other parts of the world, please write! I can put the request in the column.

73 receives many beautiful OSL cards each month. Since only one can be chosen for "OSL of the Month," Associate Editor Joyce Sawtelle slips me the best of the rest, to see if I can use them in my column. Even though these cards do not win the free one-year subscription, at least they are published for all to enjoy.

The one I really enjoyed this month was submitted by Gonzalo De Murga CX6RN for his radio club, CX1RA. The DX team from his club uses the call sign CV1R. The lighthouse on the card was built in 1876. Note the sea lions on the rocks. The lighthouse on the Isla de Lobos ("Island of Wolves") would make a dandy radio tower, don't you think?—Arnie, N1BAC

Roundup

Czechoslovakia From a letter from Jiri Pecek OK2QX, translated by OK2YN, on "Czechoslovak Radio Amateurs and the Council of Europe DXpedition TP5OK."

The Council of Europe (C.E.) in Strasbourg, France has 42 years of history, founded in 1949. The group of active radio amateurs associated with this organization initiated the Council of Europe Radio Amateur Club (CERAC), similar to the radio clubs at the United Nations and the International Telecommunications Union. The president of CERAC is Mr. W. Rossle, who is also the director of the audio visual service of the C.E. The primary force behind the ham activity is Mr. Francis Kremer, F6FQK, the appointed director of the special event station with the permanent callsign of TP2CE.

The station is situated in an extraterritorial area in the main building of the C.E. Even though it should have the same rights and status as 4U1ITU, it has not been recognized as a separate country yet by the DXCC Committee.

There have been eight short DXpeditions to TP2CE in the past. It has been proposed to activate this callsign on the occasions of admitting new members to the C.E. For example, when Hungary was admitted last November. At that time it used the callsign of TP5HA.

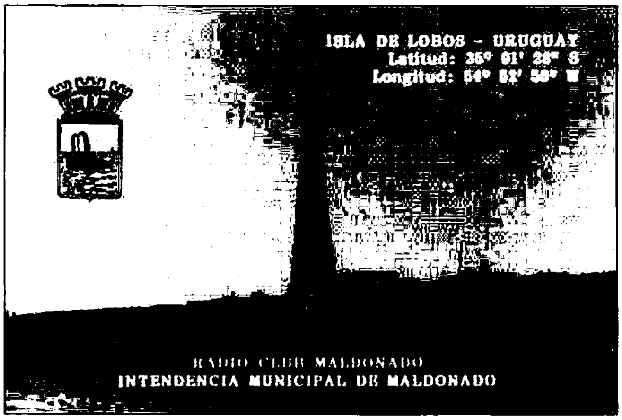

Photo A. QSL card for CV1R and CX1RA (other side) of Maldonado, Uruguay, South America.

I was given the opportunity to take part in activation of this station at the end of 1990. After exchanging some letters with our Federal Ministry of Foreign Affairs, CERAC and the representatives of the F.I.S.A.I.C. in Czechoslovakia organized the DXpedition as the event of the Association of the Czechoslovak Radio Amateurs Railroaders, as I am also president of the newly formed branch of the F.I.S.A.I.C. Thanks to the kind support of the headquarters of our State Railroads and of the F.I.S.A.I.C., the railroad transportation was at no cost.

I arrived in Strasbourg on Friday afternoon, April 26, at the railway station, but in spite of previous arrangements no one was there to meet me. I was in a strange country without knowledge of the language, but the local police gave me directions to the C.E. building.

The operation of the station was teamwork with the aforementioned people, Philippe F6GOC (physician and technician) and Santiago FD1RAY (ex EA4EII, DA4BJ, and TJ1/EA4EII), the permanent ambassador of Spain in the C.E.

At first the equipment used was a Kenwood TS-440 and SB-200 amp, but Philippe brought an ICOM IC-761 and power amp (800 watts out) the following day. The antennas were a 5-element beam for 20/15/10, a dipole for 40 meters, and a 3-element fixed beam for 80 meters. My operation was on SSB only, but the next DXpedition will be CW only.

We logged on a laptop computer which was really nice, except that the French keyboard was not the classic QWERTY keying which caused me to have to search for each key individually. To increase the speed of operation we helped one another by one operating and the other logging. This did not work very well when I was operating in the Czech language or beating down the pile-up of U-stations in Russian because the logger did not understand those languages. At those times I had to keep the log myself.

In spite of all the problems, we made 1,718 contacts in about 26 hours. The last contact was made at about 1700 on Sunday, and I was on the Eurocity Express departing at 1807.

The callsign used, TP5OK, will never be heard again, as it was used on the occasion of admitting Czechoslovakia to the C.E. as its 25th member. The next activity of this station should be later this year, probably during the occasion of admitting Poland to the C.E. with the callsign of TP5SP.

This event was good training for future DXpeditions. I am hoping to visit ZA-land in the future and wish to be the first to operate there. I am in contact with the Embassy of Albania in Prague which is attempting to help me. I hope that future DXpeditions will receive the support from the Czechoslovak Radio Amateurs Society.

The CERAC issues two diplomas: the first, the Council of Europe Award, for contacts with the member countries of the Council of Europe; the second, the European World Wide Award (EWWA), for distinguished countries from all the world round. Those interested may apply—the diplomas are worth it! *[OK2QX, Jiri Pecek, Riedlova 12, 750 02 Prerov, Czechoslovakia.]*

Japan From the JARL Newsletter: BAND PLAN: Up to now the JARL has formulated an amateur band plan by listening to the demands of amateur radio operators, but now the Ministry of Posts and Telecommunications has officially issued a band plan.

The purpose of this decision is to give the plan authority according to radio law, and to encourage efficient and orderly use of amateur bands by placing a legal requirement on all amateur radio station licensees, whether they are JARL members or not, to adhere to the band plan.

Silent Key: On May 20, the first woman amateur radio operator in Japan, Mrs. Chiyono Suzuki (nee Sugita), ex J2IX, died at the age of 84. She became the first YL ham on October 14, 1933, in pursuance of the will of her elder brother, Mr. Toshio Sugita J1DN, when he died suddenly. After WWII, Mrs. Suzuki was known to have become very active once again under the callsigns JG1WKS and JJ1SNC.

8J1RL, Antarctic: JARL has received a letter from Mr. Toyoshi Arisawa JA4EDV, a member of the 32nd Japanese Antarctic Research Expedition (JARE) team, who left Tokyo for the Antarctic on November 14, last year. The current state of amateur radio operations is:

1. General state of operations: Almost all QSOs are made on 21 MHZ during lunch break, 12:30–13:00 local time (0930–1000 UTC) Monday through Friday. The total number of stations worked as of May 21 was 560.
2. 8J1RL: A tower about 15 meters high is being used for normal operations. At present we have three projects planned—a new pole intended for Europe, a dipole for 7 MHz, and an antenna for other WARC bands.
3. Miscellaneous: HF packet was operated experimentally from May 6 to May 19. A beacon at 21.1045 succeeded in making contact with JF1SNA in Japan on May 9, 0907 UTC. This was probably the first official packet communication ever effected between Showa Base and mainland Japan.

Latvia A letter from the Kipsala DX Club in Riga: 1. Yuri Baltin YL2DX started another polar trip on July 1 to several new IOTA islands and F.J.L. in the Russian Arctic: 4K2DX, 4K3DX, and 4K4DX. All QSLs only via the manager, Mrs. Aifa Dimde, YLR-48-18, P. Kaste 18, Riga, 226048, Republic of Latvia, Europe. Please SAE with return postage. Do not put on envelopes any callsigns, and wrap all contents reliably.

2. Aifa Dimde will only keep for the next six months the logs and QSLs of the following active stations: EK1KP (Graham Bell Is., F.J.L., Aug. 1990), EKØAC (Komi Rep. & Yamal Reg., ONLY March 1991), RQ2WCY (World Comm. Year, Nov.–Dec. 1983), UAØK/UZ3AXX (Keperweem, Chukotka, July 1990), UK2GAB (1974–1984), UQ1GWX (1985-1990), UQ1GXX (1984–1989), UQØGZZ (only Jan. 1985), YL2RG (Special Stn., Dec. 1988–Jan. 1989, Oct. 1989), and YL2ØØSM (S. Morse Bicentenary, April 1991).

3. Any ham having at least five QSOs in CW during April 1991 with Memorial S. Morse stations (such as YL2ØØSM, MØRSE, VI91SM, 3A2ØØSM, I2ØØM . . . etc.) can get a splendid special TROPHY from the YLCWG in memory

times on four separate bands (i.e., at least two separate calls must have been worked).

Send only log data of QSOs along with your complete address plus 36 IRCs by registered mail to the manager, Mrs. A. Dimde, not later than Dec 1, 1991.

4. New QSL routes for YL1XX, YL2DX, and YL25RF: 226001, Riga-1, P.K.10, Ostrzygallo, Republic of Latvia, Europe. Please mail as above, and without the telltale bulge of a folded SAE.

5. The Soviet QSL Bureau, Box 88 Moscow, does NOT work for Latvian hams (all YL, UQs) any more.

Lithuania *[Article from a Colorado newspaper read during my vacation.—Arnie]* From the Rocky Mountain News, July 14, 1991, by Holger Jensen, News International Editor: Lithuanian ham told world of Soviet invasion. "One of the unsung heroes of Lithuania's drive for independence is Gintas Sakenas, a ham radio operator better known to American hams by his callsign LY2BKW.

"When Soviet Interior Ministry troops, the notorious Black Berets, invaded Vilnius, the capital of Lithuania on Jan. 13, he was the first to inform the outside world.

"For 14 hours, Sakenas was the sole source of uncensored information from his homeland—the Soviets had seized all regular broadcast stations, TV networks, and other news outlets in Lithuania, and had surrounded parliament."

Along with information about the situation, Sakenas also provided a relay from hams in the parliament building. After 14 hours of operation, he received a tip that the Soviets had traced his signal and he had to shut down. Several weeks later he was able to return to the air to reassure hams that he was okay.

Sakenas was in the United States as a treat provided by four American hams: Richard High WØHEP of Aurora, Colorado; Budd Drummond WJ6Q of Redding, California; Wayne Peterson of K6ZSJ of Woodside, California; and Chuck Carpenter N6CFQ of Riverside, California.

"Sakenas is convinced his republic eventually will get its independence. And he concedes he probably won't be able to take any more two-month vacations when it shifts from a state-controlled to a free-market economy." But, Sakenas said, "It will be worth it. We were independent before Stalin annexed Lithuania, so we know how to stand on our own two feet."

Saudi Arabia Media Release from the Ministry of P.T.T., Kingdom of Saudi Arabia: Saudi Arabia will display the Kingdom's up-to-the-minute communications technology in a pavilion of traditional Arabian architecture during the world's most prestigious telecommunications exhibition, Telecom 91, this October 7–15 in Geneva, Switzerland. The theme of the Saudi pavilion will be "The Cradle of Islam Speaks."

The Saudi Minister for Post, Telegraph and Telephone, Dr. Alawi Darweesh Kayal, said Saudi Arabia's display would be a significant part of Telecom 91, the 6th four-yearly world telecommunications exhibition and forum.

The Kingdom's telecommunications web, including 5,000 kilometres of coaxial cable and more than 450 microwave radio towers covering 15,000 kilometres, is considered the Middle East pace-setter, and one of the world's most modern networks. It is among the first to move towards all electronic telephone exchanges. It combines satellite, microwave radio, optical fibre, and submarine cable systems.

Switzerland From the International Telecommunications Union (ITU) Press: With the aim of highlighting worldwide production of quality films and videos, the ITU will host the 6th International Film/Video Festival on Telecommunications and Electronics: GOLDEN ANTENNA 91, in Geneva from 7–15 October 1991. This exhibition has met with increasing success since 1971. It is open to the 164 member countries of the ITU, to exhibitors at TELECOM 91, and to representatives of the telecommunication industry.

As of 10 June the headquarters had received 78 entries from 18 countries and three regional organizations. *[What I find interesting to note is that Japan and the Japan Amateur Radio League, Inc. was the only country and organization to have submitted a ham oriented film/video as of June 10. Their presentation is on JAS-1b/FUJI-2, Amateur Satellite Communications.—Arnie]*

Yugoslavia/Slovenia Packet message passed on by Ron Gang 4X1MK as sent by Iztok YU3FK: *[The packet message was sent to ALL BBSs in Europe on the subject of "war and hams" in Slovenia.—Arnie]* The message tells of how the hams in Slovenia responded to the emergency. Most of the ham communications were helping the press (some telephone lines were broken) and the Red Cross. A lot of personal requests were handled by the hams. Most of the operations were found on 2m and 70cm FM, and a net was on 3.605 SSB.

Luckily only one ham installation was destroyed, even though many of the sites were attacked because they were TV and communication centers. Even though the 23cm backbone was disrupted by these attacks, the 2m links were ready, and the YU3 packet network remained fully operational. No harm was done to the 2m and 70cm FM repeaters.

Packet node 4N3H was probably the first ham packet node to be destroyed in a military attack. It had four antennas on 23cm to 38,400 baud YT3MV 23cm station (4N3H-12), a 2m port on 144.600 (4N3H), and a converse node 4N3H-3. They were also developing a wide-bandwidth 19,200 baud Manchester user access node on 70cm.

Writes YU3FK: "When unexpected attack of YU Army to Slovenija happened, the first hams reaction was: be QRV, stay tuned . . . we blocked military repeaters and simplex channels on 2m . . . . Later on, we were requested not to make QRM on military QRGs because we blocked channels so effectively YU3 intelligence could not get any information from military communications.

"As my role in packet, my first action was to check network. I sent a few bulletins with emergency instructions to BBSes . . . When army started bombing of TV and communication centers, where most packet nodes were, we prepared secondary links . . . ."

Parts, Kits, and Scrounging

Most of the mail I receive is brief, and many of you take advantage of the mini-kits I put together. I hope this service is valuable to you. With the vast quantities of surplus material available in Southern California, I am able to obtain the components and PC board, minimizing the cost of the projects.

Sometimes the time and effort required to ferret out these items becomes a consuming burden, but the search and acquire mission built in me is quite strong. I look for items not in one's or two's, but in large quantities. The prime reason that I provide components and kits is to promote homebrewing.

I try to combine the basic starting block, a PC board, and key components at a modest cost to cover expenses. Some of the components required for these microwave and VHF projects are not easily found in your local parts store. Try to purchase a chip capacitor in almost any city, and you will meet more problems than you started with.

If you can't make it to a large hamfest like Dayton and stock up for the winter, you must depend entirely on mail-order houses or some really good scrounging. That's OK, but if you must purchase everything on a part basis, costs can be quite high.

Some of you asked about where you could purchase a small quantity of #26–36 guage wire for winding coils. I'd never given something this inexpensive a second thought. To me, this item is readily available, and I never considered how tough it could be to obtain in other parts of the country. I buy it in a scrap metal yard at $2 a pound. In the future, I will include some wire in the kits I put together, or I'll send it on request, when available. Keep in mind that I am not an electronics store, and I don't have a full stock of components; I am just trying to be helpful.

Mailbox Questions

John VE4HL, picking up an old issue of *73* and reading my column, asks an often-asked question: "Is the kit still available and the price still the same?" Bob WA4JOM asks other common questions: "Do you have a packet address?" "What are you offering the microwave explorer?" "What is the price?" George KD9EN inquires about parts: "Do you have any Gunn diodes or Gunn oscillator cavities?"

The question about price is easy to answer. The kits still cost the same. At least for the present, I haven't made any adjustments to keep pace with the increases in postal and shipping rates.

As for a packet address, I don't have a packet station on the air yet. I have neglected this mode of operation primarily due to my main interest in microwave operation.

The MOSFET (for the switching power supply) and the Gunn diodes are still available, as are most of the printed circuit boards from past projects. I make my own PC boards, and as such, have many other boards available that I have never listed before. I have a 100-year-old graphic arts camera that takes a piece of film 12" x 10", and allows me to reproduce almost anything. I also have large quantities of sheet film, and can help you prepare a negative. Drop me a line, and time permitting, I might be able to help you out on one of your projects.

The next frequently asked question is, "What is the most popular kit?" I believe It's the 30 MHz IF amplifier, Gunn modulator kit, for use with a burglar alarm type (10 GHz) Gunn oscillator and detector. It can be used directly with the MaComm Gunplexers™ unit. See the following list for the month and year of the issue that this appeared in *73*. Since then, an improved PC board has been developed, covering most of the frills while still using the TDA-7000 chip. This single chip FM receiver made this kit possible.

About this time I coined the phrase "microwave building blocks," referring to modular components used in upgrading and constructing devices. Rather than building on a motherboard, the project consisted of interconnected, easy to change modules. Most of the kits are for constructing these modules. They range from simple items to a miniature microwave RF amplifier for 10 GHz.

Kits Available

Here is a list for your convenience:

•1296 DBM (Oct. 1987). Cost, $10. The 1296 MHz mixer is a 1-1/2" square of 0.015" Teflon™ PC board. The double-balanced mixer was intended for 1296 MHz. It works well from 450 MHz to 2 GHz.

•1296 ATV Converter (Oct. 1985). Cost, $5. This simple voltage tune converter for ATV on 1296 MHz uses a single MRF-901 oscillator (the IF amplifier uses one, too).

•10 GHz Preamp (Aug. 1989). Cost, $20. The 10 GHz preamp uses two MGF-4102 GaAsFETs with a no-tune design, giving 18 dB gain at a 3 dB noise figure. This is the amplifier that I use for receive; in transmit, it drives my TWT for high power on 10 GHz SSB. An additional power supply for the preamp that uses a switch mode power supply for negative 9 volts (gate bias) is included with the PC board for an additional $5.

•60 kHz Antenna (Feb. 1990). Cost, $14. The original surplus ferrite rods for this kit are out of stock. A replacement exists, but it's full-size, instead of five rods like the original kit. The cost of the full-size rod, plus additional postage to ensure its arrival without breakage, has increased the price. With the WWV 60 kHz, the 60 kHz antenna is a calibrator for your frequency counter's timebase.

•10 GHz Fun 30 MHz IF System for Gunn Transceivers (April 1990). Cost, $10 for PC board and TDA-7000 single chip FM receiver. The 10 GHz, 30 MHz IF system is a single chip transceiver controller at 30 MHz for use with a Gunn oscillator on 10 GHz wideband FM. It controls voltages and modulation for the Funn oscillator. The TDA-7000 is a complete 30 MHz FM receiver on a single chip.

On their DXpedition to Baja California, Chip N6CA and Jack N6XQ spent many evenings camped along the beach.

•CW EPROM Keyer (June 1990). Cost, $12.50. The CW EPROM is a keyer identifier with your callsign built in for use with a 10 GHz wideband FM system. Turn on DC power, and it outputs your call in low level audio to modulate the 10 GHz WBFM oscillator.

•FET Switching P/S (Aug. 1990). Cost, $15. Extra pair of FETs, $5. The FET switch Is a simple controlled power supply that can be used to develop low power 110 AC (100W) or to construct a toroid transformer and convert 12 volts DC to 24 volts or more. It's about the size of a cigarette pack. I use one to obtain 1200 volts at 4 mA for the photo multiplier part of a laser receiver.

•5.6 GHz Converter (Dec. 1990). Cost, $15. PC board for 5.6 GHz, both receive and transmit MGF-1302 amps. Dual mixers with preamp for 2 meter IF, and transmit attenuator for transmit at 2 meter drive. Requires a local oscillator source, either crystal multiplier or brick phase-lock loop. Design by DJ6EP and DC0DA, courtesy The North Texas Microwave Society.

•6 GHz Brick PLL Oscillator (Dec. 1990). Cost, $50. The brick Is a phase-locked oscillator requiring modification of its output filter. (I re-tune them for you.) The brick requires an external crystal oscillator at approximately 100 MHz. Shortly (next month) a 10 GHz PLL brick will be offered that has the internal crystal oscillator and oven control.

•Gunn Diodes 50 mW at 10 GHz (Jan. 1991). Cost, $5; 100 mW Gunn diodes at 10 GHz, $10. The Gunn diodes are still available, and the 50 mW devices are no problem. However, I am having difficulty obtaining 100 mW devices. In bench tests, I have to test about 20 devices at 50 mW before finding a hot one at 100 mW.

•10 GHz Slot Antenna (March 1991). Cost, $40. This is a beacon waveguide antenna constructed from a section of WG-16 waveguide. It produces about 6 dB gain, and is omnidirectional. The kit includes all parts, a precut and machined waveguide with top shorting end plate, and a gold plated brass waveguide (WG-16) flange.

That's the list for now. More will be added to this list in the future. I hope this answers your questions about the kits. For more information, write to me, or to *73 Magazine* for back issues or copies of the articles and columns. Better yet, subscribe and don't miss out.

Recent Mailbox Question

Larry (callsign pending) has heard that it is possible to work DX at VHF and UHF frequencies by bouncing signals off the moon. He writes: "Is this true, or is someone pulling my leg?"

Many amateurs work moonbounce (or EME, Earth-Moon-Earth) from continent to continent on frequencies from 2 meters to 10 GHz. Look in the back sections of ARRL handbooks and you'll see equipment for this purpose.

Houston TX 77083-5640

OSCAR-22 Launched!

On July 17, five payloads were placed in low earth orbit by the Ariane space V-44 launch from Kourou, French Guiana. They included the primary payload Earth Resources Satellite (ERS-1) and four micro-satellites. Among the microsats was UoSAT-F, now called UoSAT-5 or UoSAT-OSCAR-22. OSCAR stands for Orbiting Satellite Carrying Amateur Radio.

The other microsats included TUBSAT, SARA and ORBCOM-X. They were mounted on the Ariane Structure for Auxilary Payloads (ASAP). This arrangement of mounting small satellites on a ring at the base of the main payload was used successfully for the January 1990 launch of six amateur satellites, OSCARs 14–19.

TUBSAT is the first microsatellite built by the Technical University of Berlin. Its mission is to track storks (really, storks!) with radio location beacons. It also incorporates an experimental Charged Coupled Device (CCD) camera star tracker for satellite attitude determination.

SARA is a radio astronomy satellite designed to listen to Jupiter's radio emissions in the 2–15 MHz range and transmit telemetry on 145.955 MHz. This project came from ESIEE SPACE, a club at the French "Ecole Superieure d'Ingenieurs en Electrotechnique et Electronique." Although ESIEE SPACE was originally founded to build and launch experimental rockets, the group built their first satellite in conjunction with the French National Space Agency, CNES. Some have questioned their use of an amateur frequency for the downlink, but it's up now, on the air, and can't be changed.

ORBCOM-X is a small satellite built by Orbital Sciences Corporation as a prototype of their proposed constellation of low-earth-orbit communications satellites. The team responsible for this effort included AMSAT Vice-President of Engineering Jan King W3GEY, Gordon Hardman K7KD, and Jeff Zerr. They were all pivotal players in the AMSAT Microsat Project.

A Look at UoSAT-OSCAR-22

U-O-22 is the fifth satellite in the University of Surrey series of small, low-cost spacecraft. It uses the same basic structure and electronics configuration as UoSAT-OSCARs-14 and -15 but with several differences. Originally the satellite was to have no amateur radio operations on board. Its primary mission was to provide PACSAT-style communications for medical and technical information services in developing countries on nonamateur frequencies. Organizations including SatelLife *[see "QRX" in the September issue]*, VITA, and the National Science Foundation were involved. AMSAT's former President Vern "Rip" Riportella WA2LQQ is the SatelLife Technical Director, while Jon Metzger N1IJP is the SatelLife Ground Station Manager. The HealthNet communications operation is still the primary focus of the satellite, but other experiments and ham radio operations are now a part of the package.

The U-O-22 Solar Cell Technology Experiment (SCTE) monitors the performance of a wide range of solar cells mounted on the spacecraft. Cells made from indium phosphate, gallium arsenide, and silicon are included to determine the long-term effects of space radiation on the electrical characteristics of the different cells. This will assist future satellite designers with solar cell choices for future spacecraft. The space radiation is monitored by RADFETS. The readings are then sent by the telemetry system to ground stations for study.

U-O-22 carries a CCD camera. The images are black and white with 256 grey levels and a resolution of 578 by 576 pixels. The images seen by the camera are about 1000 miles square, allowing easy identification of ground features. The pictures are captured to the onboard RAM disk for later broadcast to ground stations.

The pictures are sent via packet on 435.120 MHz at 9600 bps using Frequency Shift Keying (FSK). Image display programs were not readily available in the first days after launch, so several pictures were converted to GIF files and distributed to various BBS systems, including CompuServe and the Dallas Remote Imaging Group (DRIG) BBS (214-394-7438). Some of these processed pictures were also uplinked to U-O-14 for transmission from that satellite. U-O-22's gravity-gradient and magnetorquer attitude control system provides a stable system for reliable earth imaging. The satellite camera is always aimed toward the earth.

Ground Station Equipment

Stations already equipped for activity via U-O-14 need no changes to receive the data, messages and pictures from U-O-22. New users will need a 70cm receiver, FSK demodulator, and a packet terminal node controller (TNC) capable of KISS operation. Although 9600 bps modems are more difficult to work with compared to 1200 bps systems, more information has become available on 9600 bps systems from AMSAT both here and in the United Kingdom. Simple omnidirectional antennas are adequate for U-O-22 reception.

Several software programs have been in development for decoding and displaying telemetry from U-O-22, but the most important software is either PB.EXE or NET.EXE. These programs are designed to receive the Broadcast Protocal files sent from the satellite. They are available as shareware through BBS systems or directly from AMSAT-NA in Washington for a handling fee. Call (301) 589-6062 or write to AMSAT-NA, 850 Sligo Ave. #600, Silver Spring MD 20910-4703.

Other programs of interest from AMSAT-UK in London include DTLM.EXE for displaying telemetry from the UoSATs and microsats, SPLOT.EXE for graphing telemetry results, and UO5TLM.EXE for specifically collecting, displaying and archiving U-O-22 telemetry. Programs for picture display are expected soon. Some of these programs may also be available from AMSAT-NA.

U-O-22 Commissioning

When U-O-22 went into orbit on July 17, it was launched with all systems off. During the first pass over the United Kingdom, the ground control station powered the satellite up with the 70cm transmitter operating at the 2 watt level. Data was at 1200 bps. The onboard computer was then activated and the backup transmitter turned on because the primary transmitter was acting up with intermittant output.

After six passes over the UK, the data downlink was switched to 9600 bps and several systems including the AX.25 packet output and RAM disk were successfully activated. The previous transmitter problems were no longer occurring, and all systems seemed operational.

Forty-six hours after launch, the magnetorquers were enabled to stop the tumbling motion of the satellite. A day later U-O-22 was sufficiently stable to extend the gravity-gradient boom. Unlike previous UoSATs, where the extension of the boom is gradual, this one deploys telescopically with one firing to a length of 16 feet in only a few seconds. Gravity-gradient lock was achieved, and the satellite orientation became stable with the camera always aimed toward the earth. The magnetometer and sun angle sensors work in conjunction with the onboard attitude control software to maintain the satellite's position using the magnetorquers.

Four days after launch the ground control team began work with the CCD camera experiment. The first picture was downloaded to NK6K in California. It showed overexposure and cloud cover. Subsequent shots displayed spectacular views of the Mediterranean with excellent clarity and easily-identifiable land features. For those with CompuServe access, the first good picture file showing a clear view of Italy can be downloaded from the HAMNET as CCD1A.GIF.

By July 29, the initial phase of U-O-22's commissioning was complete. All the subsystems had been exercised and proven functional. Some debugging of the onboard computer and the CCD Transputer software continues, but for now, the amateur side of this new satellite is performing flawlessly.

UoSAT-OSCAR-22 Frequency Plan

Downlink:	Uplink:
435.120 MHz	145.900 MHz
9600 bps FSK	9600 bps FSK
1200 bps AFSK (backup)	1200 bps AFSK (backup)
5 watts or 2 watts	

ABOVE AND BEYOND

Continued from page 60

Microwave Experimenters Manual covers EME calculations in depth, and gives a very good history of its development and applications.

DXpedition to Baja

Recently Jack N6XQ and Chip N6CA took a trip to Baja for some DXing, which required some intensive navigation of Baja's narrow roads and nasty potholes, not to mention wandering burros. Jack and Chip thought they were home safe when they landed at the Tijuana airport. (They left their van in lower Baja for a return trip on July 8 for more hamming activities.) Little did they know that the most dangerous part of the trip was about to begin with a Tijuana taxi trip to the border. Jack stated that "The driver obviously had computer training, as his throttle had a binary control." They almost had two serious accidents in the very short trip to the border.

Jack reports that cautious driving rewarded them with a pleasant trip. In seven days they had traversed over 17 of Baja's 24 different grid squares. They camped on some beautiful beaches, including one in DL37 for two nights. Finding camping spots in Baja is easy, as the state is sparsely populated and forest rangers will give you directions. The Sea of Cortez was noticeably warmer than the Pacific Ocean. The last day they spent on the beach in DL53, with a refreshing breeze.

The QSO count came in around 250, with the bulk on 6 meters. Nice double hop to the East Coast on Saturday morning of the contest weekend, with strong "E's" from DL43 to Southern California, Nevada, and Arizona, on the evening of June 11. Several stations with whip antennas dropped power to less than a watt. On the 12th, operation was from Cabo San Lucas DL42 and DL52, but luck ran out and there was no opening. Camping in DL53, they caught a few more "E" openings into Colorado and meteor scatter propagation into Phoenix and W5FF. Thursday morning the 13th was the biggie, with openings into the 5, 6, 7, and 0 call areas. On the way to the La Paz airport, a few 2 meter tropo and meteor contacts were made.

One highlight of this trip was that Chip worked Bernardo XE2HWB on 6 meters, and this was Bernardo's first contact on 6 meters from his own country. Later Chip and Jack met Bernardo, his family, and Antonio XEHWH. Bernardo operates from La Paz DM44 with 10 watts and a 3-element antenna. Chip and Jack have constructed a beacon for Bernardo, and hopefully it will be operational by the end of July. The beacon will be solar powered and have 1 watt output operating on 50.008 MHz. During the solar eclipse, Bernardo operated as 4B2SOL on 2 and 6 meters.

Stay Tuned!

Next month we'll cover modification of brick oscillators. As always, I will be glad to answer questions relating to VHF/UHF and microwave areas. Please include an SASE for a prompt reply.

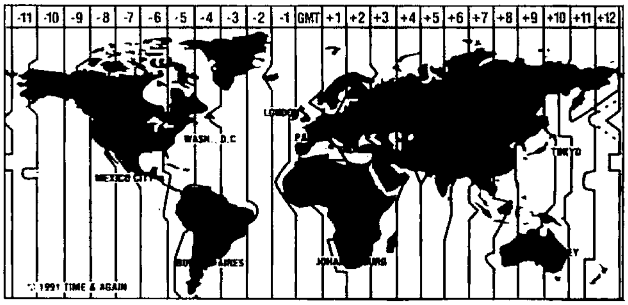
NEW PRODUCTS

Compiled by Linda Reneau KA1UKM

AMERICAN DESIGN COMPONENTS

The 1992 spring catalog of computers and computer-related parts and components at far below OEM prices is now available from American Design Components. Geared to the needs of hobbyists as well as manufacturers, the 54-page catalog features ICs, components, crystals, fans, connectors, batteries, LEDs, switches, power supplies, disk drives, monitors, and much more.

Copies of the catalog are available without charge from *American Design Components, 815 Fairview Ave., Fairview NJ 07022. Tel. (800) 776-3700; (201) 941-5000.*



TIME & AGAIN

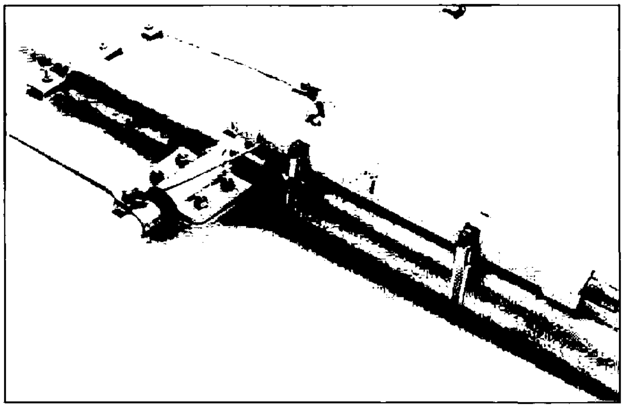
Time & Again Co. is proud to distribute the World Time Zone Map decal, which can be placed on a shortwave receiver or any other object. You can reference international time zones at a glance. These decals are made of a high quality polyester, and are self-adhesive for easy application to any surface. They are attractively toned with silver continents and medium-light blue oceans. The two sizes available provide for accommodation on small areas.

The 2¼" x 4¾" size is $2.00; the 1¼" x 3¾" size is $1.50. You can buy both for $3.00. Prices include tax. Send SASE and payment to: *Time & Again, P.O. Box 306, Dickinson TX 77539.*

MFJ ENTERPRISES, INC.

MFJ's new low pass filter, the MFJ-704, reduces TVI from harmonics and spurious signals generated by your HF rig. It attenuates frequencies above 40 MHz, using a proven 9-pole Chebyshev low pass filter design and MFJ low pass filter technology. The compact 8¾"D x 2¾"W x 3"H filter handles a full 1500 watts of power with low SWR. Insertion loss is less than 0.5 dB. It comes with a one-year guarantee.

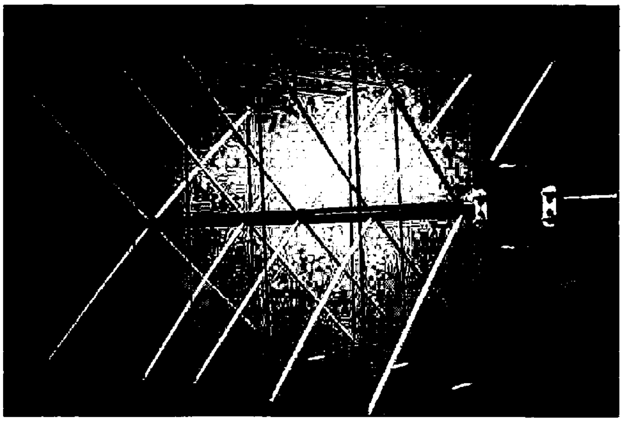
Price, $40. Contact *MFJ Enterprises, Inc., P.O. Box 494, Mississippi State MS 39762. Tel. (601) 323-5869. Fax: (601) 323-6551. Order toll free at (800) 647-1800.* Or circle Reader Service Number 208.



AZTEC RF

Aztec RF now has a deluxe, external ferrite bead-over-coax 1:1 balun. Now recognized as the most effective method of constructing a coreless balun for 160–10 meters, external ferrite beads over Mil-Spec Teflon™ coax ensures reliable choking action for clean radiation patterns and no measurement errors. Teflon UHF or N connector has a shield-hood for full coaxial isolation of current paths. Stainless steel units are epoxy-potted.

Model DXB-1 has eyes for wire antennas; Model DXB-2 mounts on all yagi booms with kit supplied. Each costs $50 plus $4 shipping. *Aztec RF, Box 1625, Valley Center CA 92082. Tel. (619) 751-8610.* Or circle Reader Service No. 205.



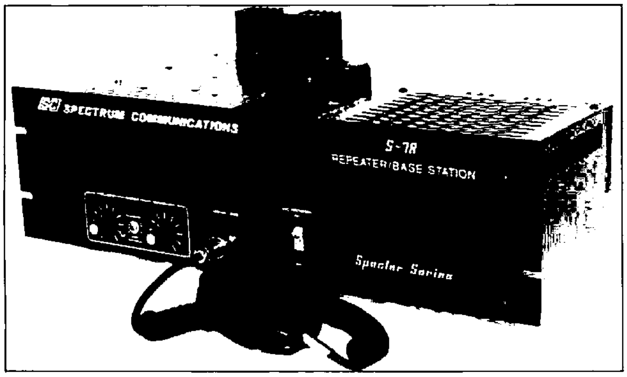
PERFORMANCE ELECTRONICS

Performance Electronics can give you plenty of reasons to own a quad. They offer 2m, 220 MHz, and 440 MHz quads in easily assembled, complete kits. These all-fiberglass antennas have proven, tested designs, a 48" mast, a 60" pre-assembled coax with connector, and are easily stacked for better gain and directivity. Designed to withstand a 40-foot fall, they come with a two-year warranty. Customers receive personal support for operation over the entire legal range and in the respective modes.

Price range, $80–$100. For detailed information, write *Performance Electronics, P.O. Box 310, Conestee SC 29636. (803) 299-1072.* Or circle Reader Service Number 206.

HART PUBLISHING

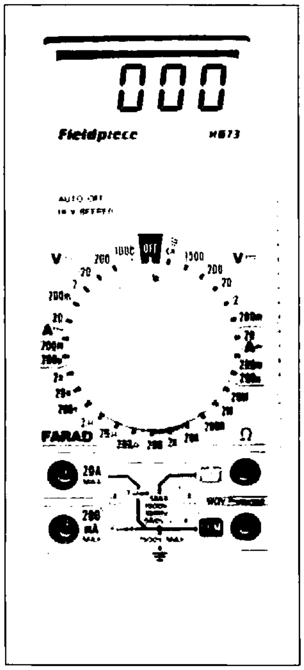
The *1991 Amateur Radio Mail Order Catalog*, published every January and July by Hart Publishing, lists 100 free catalogs along with equipment, businesses, publications, and resources for hams. A single issue is $7, postpaid. A two-issue subscription for this 40–50-page publication is $13. Send your subscription payment to *Hart Publishing, 767 S. Xenon Court, #177, Lakewood CO 80228.* Send also your club's newsletter, or any news and information you think Hart Publishing may be interested in including in their catalog.



COMMUNICATIONS CORP.

Spectrum Communications introduces the new, low cost "Specter" Series S-7R basic repeater/base station. This lightweight but rugged desktop unit also has a 19" rack mounting. The S-7R is available on VHF (10, 30, and 150W), midband, and UHF (10, 40, and 100W), with 100% duty cycle. High sensitivity and selectivity, crystal-controlled, and easy to service, the S-7R can be interfaced to any repeater controller via the proper jack. Numerous accessories are available, such as CW IDer, CTCSS, community tone panel, additional receiver filtering, hand mike, duplexer, cabinet, etc.

Price, $1100. Contact *Spectrum Communications Corp., 1055 W. Germantown Pike, Norristown PA 19403-9616. Tel. (215) 631-1710. Fax: (215) 631-5017.* Or circle Reader Service Number 201.



FIELDPIECE INSTRUMENTS

Fieldpiece Instruments' HB70 Series of heavy duty "book" type digital multimeters are easy to use, with all the capabilities of the meter displayed on the meter's face. These multimeters are built for use in the field. The more control the user wants, the more he may prefer a manual ranging meter instead of an autoranging meter, especially if it's less confusing and easier to use.

Meter prices range from $99 to $179. *Fieldpiece Instruments, 8322B Artesia Blvd., Buena Park CA 90621. Tel. and FAX (714) 992-1239.* Or circle Reader Service No. 204.

MYERS ENGINEERING INTERNATIONAL, INC.

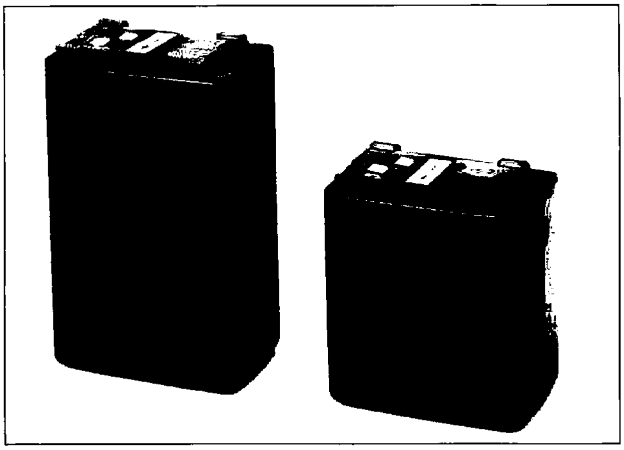
Myers Engineering offers two new yagi beam antennas: the 3-element YL-143-AM for 144–148 MHz, and the 4-element YL-224-AM for 220–225 MHz. Each antenna weighs about three pounds, permits end or center mounting with 50 ohm input impedance, and permits RF input power of 500 watts. Front-to-back ratios are 16 and 20 dB, respectively.

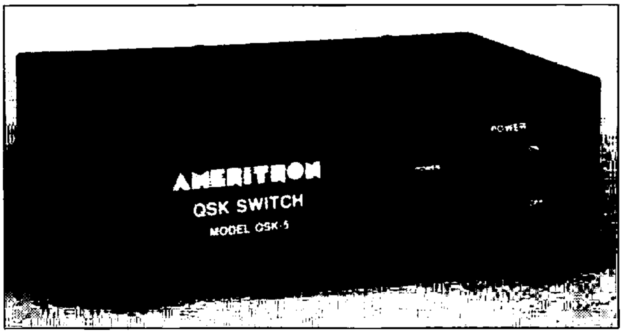
Price per antenna, $85 plus shipping and handling. For detailed specifications, contact *Myers Engineering International, Inc., P.O. Box 15908, Fort Lauderdale FL 33318-5908. Tel. (305) 572-8217; FAX (305) 572-8273.* Or circle Reader Service Number 209.

W & W ASSOCIATES

W & W Associates (Batteries "R" Us) announces the introduction of their replacement batteries for the Alinco DJ-160T/E, DJ-460T/E, and DJ-560/560E. W & W battery part #WC-500-EBP-10N is 7.2V at 700 mA. Battery part #WC-505-EBP-12N, 12V at 700 mA.

The WC-500 is $36; the WC-505 is $49. Contact *W & W Associates (Batteries "R" Us), 29-11 Parsons Blvd., Flushing NY 11354. Tel. (718) 961-2103; (800) 221-0732. Fax: (718) 461-1978.* Or circle Reader Service number 202.





AMERITRON

Ameritron announces the release of the new Ameritron QSK-5 Electronic T/R Switch for linear amplifiers. The QSK-5 gives you switching over six times faster than a vacuum relay, and works with any linear amplifier. The self-contained QSK-5 provides full CW break-in and rapid switching in digital modes as well as faster, quieter switching in SSB. It operates on 120 VAC, handles 2500W PEP and 2000W CW when the SWR is below 1.5:1. It handles 750W on RTTY and packet. An optional cooling fan (CF-5, $40) allows sustained operation at 1500W in any mode.

Price, $349. To locate your nearest Ameritron dealer, contact *Ameritron, 921 Louisville Rd., Starkville MS 39759. Tel. (601) 323-5869; FAX (601) 323-6551; (800) 647-1800.* Or circle Reader Service No. 203.

MIDIAN ELECTRONICS INCORPORATED

Midian Electronics' new ID-1 miniature Morse Code Station Identifier sends a 16-character station ID and/or 130-character message at user-programmable intervals. The ID-1 is easily programmed via a 12-button touchtone style keypad with alphanumeric characters. Other programmable features include front porch delay, code speed, Morse tone frequency, bypass for PTT queing, wait period for loss of COR input, and automatic repeat intervals. If desired, the ID-1 can also send Morse code manually.

The 1.4" x 1.1" x 0.25" ID-1 costs $90. Contact *Midian Electronics Incorporated, 2302 East 22nd St., Tucson AZ 85713-2024. Orders: (800) MIDIANS. Technical Assistance: (602) 884-7981. Fax: (602) 884-0422.* Or circle Reader Service Number 207.

BARTER 'N' BUY

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The *73 Flea Market*, Barter 'n' Buy, costs you peanuts (almost)—comes to 35¢ a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to the *Barter 'n' Buy*, Sue Colbert, Forest Road, Hancock NH 03449 *and get set for the phone calls.*

Deadline for the January classifieds is November 1, 1991.

HAM RADIO REPAIR CENTER, quality workmanship. Solid state or tube, all makes and models. Also repair HF amplifiers. A-Z Electronic Repair, 3638 East, Indian School Rd., Phoenix AZ 85018. (602) 956-3024. BNB220

SATELLITE RECEIVERS used, good for experiments. $29.00. Motor controls, $19.00. LNA's $10.00. Satellite Headquarters. (804) 239-7585. BNB231

FOR SALE: HITACHI 35 MHz DUAL TRACE OSCILLOSCOPE. Paid $600, sell $300. Like new. W. Hotine K6HH, 633 Ramona Ave., #23, Los Osos CA 93402. (805) 528-6180. BNB233

WANTED: Yaesu FT-23R-HT and pre-1980 microcomputers for museum. KK4WW. (703) 231-6478/763-3311. BNB234

NEW!! NEW!! NEW!! NEW!! SPEAK TO THE WORLD Amateur radio language guide. •Written especially for the ham radio operator •Hundreds of phrases •Volume 1—Spanish, German, French, Polish, and Japanese. •Volume 2—Swedish, Italian, Portugese, Croatian, and Norwegian •Send $10.00 per book (postage paid). **ROSE**, P.O. HAM RADIO REPAIR Experienced, reliable service. Robert Hall Electronics, 1660 McKee Rd., Suite A, San Jose CA 95116. (408) 729-8200. BNB751

WANTED: Ham equipment and other property. The Radio Club of Junior High School 22 NYC, Inc., is a nonprofit organization, granted 501(C)(3) status by the IRS, incorporated with the goal of using the theme of ham radio to further and enhance the education of young people nationwide. Your property donation or financial support would be greatly appreciated and acknowledged with a receipt for your tax deductible contribution. Please look over whatever unwanted equipment you may have, and call us. We will pick up or arrange shipping. You will receive the tax deduction, but most important, the privilege of knowing that your gift really made a difference in the education and upbringing of a child. You are invited to check into the WB2JKJ CLASSROOM NET, 1200 UTC on 7.238 MHz, also work the "22 Crew" during our special event operation October 23-25. Write us at: The RC of JHS 22 NYC, INC., P.O. Box 1052, New York NY 10002. Round the clock HOTLINES: Voice (516) 674-4072, FAX (516) 674-9600. BNB762

OCT 27

SELLERSVILLE, PA The RF Hill ARC will sponsor a Hamfest at the Pennsylvania National Guard Armory, PA Rte. 152, starting at 0800. Set-up at 0600. Admission $4. Talk-in on 145.310, 146.880, 146.520 simplex. VE Exams. Indoor and outdoor Flea Market. Contact ***Bob Buonfiglio WG3X, 361 School House Rd., Souderton PA 18964. (215) 723-1016 eves. 1800-2200.***

MARION, OH The Marion ARC will hold its 16th annual Heart of Ohio Hamfest/Computer Show from 0800-1500 hours at the Marion County Fairgrounds Coliseum. Tickets $3.50 in advance, $4.50 at the door. Tables $7. Talk-in on 146.52 simplex or 147.90/.30 repeater. Contact ***Dan Burns N8JMF, 844 Robinson, Marion OH 43302. (614) 382-2384.***

SPECIAL EVENT STATIONS

NOV 2-3

CHARLOTTE, NC The new Amateur Radio Education Center at the Discovery Place science museum will celebrate its opening by operating from noon (Eastern Time) Nov. 2-noon Nov. 3. The Mecklenburg ARS will operate the station as W4BFB, primarily on phone in the bottom 50 kHz of the General phone subbands on 75, 40 and 20 meters and around 28,400 kHz. For QSL and Certificate, send QSL card and 9x12 SASE with 2 units of first class postage to ***Ralph Eubanks, 6021 Coatbridge Lane, Charlotte NC 28212, USA***

OCT

VERMONT Special Event Stations from Vermont will be operating 25 kHz up from the bottom of the Novice and General bands to help celebrate Vermont's 200th Birthday. RTTY/AMTOR etc. will be in the digital subbands. To obtain a Special Bicentennial Certificate, send $1 and a SASE to ***Amateur Radio Bicentennial Project, PO Box 200, Graniteville VT 05654.*** Foreign stations, send only SAE and IRC's to cover postage.

OCT 5

OZARK, AL The Dale County ARES will operate WD4NXN 1400Z-2300Z to commemorate the annual Claybank Jamboree Arts and Craft Show. Operation will be in the 40, 20 and 15 meter General HF subbands and the Novice 10 meter phone band. For QSL, send contact number and SASE to ***Special Event, WD4NXN, 208 Cherry Lane, Ozark AL 36360-2811.***

OCT 5-6

CAPE COD, MA WB1U will be operating from the Marconi Wireless Station site at South Wellfleet (starting 1400Z) to commemorate its 90th Anniversary (construction started in 1901). Frequencies: General portions of 15, 20, and 40 meters (lower 25 kHz) and the Novice portions of 10 and 80 meters. For Certificate, send QSL and 9x12 SASE to ***Ray Hilson, 6 Sherman Place, Norwalk CT 06851.***

PITTSBURGH, PA The Breezeshooters ARC will operate W3XX from the USS Requin SS481, a Trench Class WWII submarine, from 1400Z-2200Z each day, to celebrate the opening of the Carnegie Science Center. Frequencies: 28.495, 21.365, 14.245. For a QSL card send an SASE to ***WB3LHD, 326 Sunset Dr., Bethel Park PA 15102.***

BRUNSWICK, MD The Brunswick Radio Amateur Groups are planning special event operations for the annual Brunswick Railroad Days Celebration. Brunswick Hams will be signing with location on phone and "/BSWK" on CW from home QTHs and the festival grounds. Frequencies: 28.300/.325 MHz (SSB) in the daytime; 14.250/.265 MHz (SSB), 7.100/.115 MHz (CW) and 3.675/.700 MHz (CW) evenings and overnight, plus local VHF and UHF. For a commemorative photo QSL of Brunswick Museum's Centennial Quilt, send QSL to ***BRAGS, PO Box 143, Brunswick MD 21716.***

OCT 12-13

QUILCENE, WA The West Seattle ARC will operate Station W7AW during the "Quilcene Slug and Oyster DX Festival" from 1600 UTC-0400 UTC Oct. 12 and 1600 UTC-1900 UTC Oct. 13. Frequencies: 7.225, 14.225, 21.125. For a commemorative QSL Certificate showing a friendly slug and oyster at play, send QSL and a large SASE to ***B. Todd, 3719 59th Avenue SW, Seattle WA 98116.***

COLUMBUS, OH The Columbus ARA will operate Station W8TO in conjunction with the Columbus USA Festival, from Oct. 12 at 0000 UTC-2400 UTC Oct. 13. Frequencies: 7.240, 14.340, 21.375, 10m Novice phone band. A commemorative QSL is offered to those who confirm contact with W8TO. A Certificate will be sent to stations who contact at least 10 Columbus area stations. Plaques will be awarded to the two stations making the most contacts. Exchange name, QTH and signal report. Send QSLs and logs to ***Roger Ozwonczyk WB2EIG, 283 East Longview Ave., Columbus OH 43202, USA.***

ROBINS AFB, GA The Middle Georgia RA will operate KN4IE from the Museum of Aviation from 1200Z-2000Z to remember and preserve aviation history on the 44th Anniversary of the breaking of the sound barrier. Airpower or aviation notables may be on the air for this event. Frequencies: (SSB) 3944, 7244, 14244, 21344, 28344; (CW) 3644, 7144, 14144, 21144, and 28244, QRM/QRN permitting. For a unique QSL card and/or certificate signed by World War II Ace and *God is My Co-Pilot* author BGen. Robert L. Scott, Jr., Retired, QSL with SASE to ***Dave Shiplett WL7ACY, PO Box 1076, Warner Robins, GA 31099.***

OCT 18-19

GILMER, TX Hams of Upshur County will operate N5QZK in conjunction with the 54th annual East Texas Yamboree. Operation will be in the General portion of the 40 and 20 meter phone subbands, and in the Novice 10 meter phone subband. For a certificate send QSL and a 9x12 SASE to ***KB5PAD, Rte. 2, Box 114, Diana TX 75640.***

OCT 18-20

UNION, KY The Northern Kentucky ARC will operate K4CO 1400-2100Z from Big Bone Lick State Park in conjunction with the annual Salt Festival. Operation will be on 40, 20, 10 meters, and 147.375+ repeater. For a certificate, send 4x9 SASE and contact number to ***NKARC, PO Box 1062, Covington KY 41091.***

OCT 19

ALCATRAZ ISLAND/PRISON The Sacramento ARC will operate from the Officer's Dining Hall of Alcatraz Prison 1700-2300 UTC. Three transmitters will be on SSB frequencies 7.240, 14.280, 21.350 and 28.350 as best propagation permits. QSL with SASE to ***S.A.R.C., PO Box 162903, Sacramento CA 95816.***

WEST LAFAYETTE, IN The Purdue ARC will operate W9YB from the campus of Purdue University 1400-2200 GMT, to celebrate Homecoming Weekend. Frequencies: 7.280, 14.280, 21.380, and 28.480 MHz (±20 kHz) during the day as propagation and QRM allow. W9YB, located in the West Tower of the Purdue Memorial Union, is open to campus visitors at this event.

OCT 19-20

ATHENS, GA The Athens RC will operate WA4BKF to celebrate Athens' most unusual property owner, the "Tree That Owns Itself." Operation will be in the General portions of the 80-15 bands and Novice 10 meter. For special QSL, send QSL and No. 10 SASE to ***Bill Strickland WA4FVT, 355 Segrest Cir., Athens GA 30605.***

OCT 23-25

NEW YORK CITY, NY The "22 Crew" operating WB2JKJ from the HQ of the Radio Club of JHS 22 will celebrate the 11th anniversary of the Club and their educational program EDUCOM. Join them on 7.238 from 1200-1330 UTC then on to 21.395 till 2000 UTC, Wed. thru Thurs. For an awesome QSL and surprise package, write to ***RC of JHS 22, PO Box 1052, New York NY 10002,*** or FAX it to us at ***(516) 674-9600.***

OCT 31-NOV 1

BREVARD, NC The Transylvania County ARC will operate W4EHV to celebrate Halloween from the Devil's Courthouse in Transylvania County. Operating hours will be from Oct. 31 at 2100Z-0200Z Nov. 1. Frequencies: (SSB) 3.860, 14.295, 21.365, 28.335, 50.150, 144.25; and 146.52 FM Simplex. VHF Packet, KN4GC V NCAVL2.NC. For certificate, send a legal size or 9x12 SASE to ***W4EHV, Erik Hansen, PO Box 10, Sapphire NC 28774.***

Continued from page 46

capacitance, and set both switches to about the center of their ranges.

With the transceiver adjusted for a few watts output on CW, key the transceiver and adjust both wafer switches for the lowest SWR indication. Then, adjust C1 while changing the position of one or both wafer switches, one position at a time, until the SWR is as low as possible. This usually will be 1.1:1 or lower with most installations.

There may be more than one pair of switch positions which produce an SWR below 1.5:1. Although 1.5:1 is satisfactory for all modern transceivers, changing one or both switches a single position one way or the other should allow adjusting C1 for an even lower SWR indication.

Although it may be necessary to change the positions of the wafer switches when going from one end of 80 meters to the other, on the higher bands a slight adjustment of C1 should allow the SWR to be brought back to 1.1:1.

Conclusion

The low-pass antenna tuner is an efficient, wide-range, easy-to-build-and-use accessory for your station. It covers the 3–30 MHz range. It can also be used as an L-circuit tuner to feed random wires as well as low- and high-impedance end-fed antennas. Because it also reduces harmonics by as much as 20 dB, using it properly will endear you to the XYL or OM—and to your neighbors. 73

H-T POWER FOR LIFE!

The Quantum Ham Battery™ may be the last rechargeable battery you'll purchase. Its 12 volt 2.1 **amp hour** capacity packs up to six times the power of H-T nicad packs.

A simple coiled cord connects Quantum's power to your H-T. If you buy another H-T just get another cord — without the additional cost of new batteries and chargers. The Ham Battery will power all sorts of 12 volt gear — past, present and future.

You'll always know how much power remains. The battery's status is continuously monitored by a unique L.E.D. display. Its sealed lead cells maintain charge for months and recharge reliably to 100% capacity without the "memory" effect of nicads.

You'll have the power you need when you need it—for emergencies, events, field day, camping, boating, camcorders, cellular phones... even two at once with dual outputs.

Discover what so many other hams have already discovered: the ultimate solution for long lasting H-T power.

Frequency Specification

Boy, did I open a can of worms a few months ago! Last July I asked for your opinions on specifying RTTY frequencies.

To recap the problem, for those who may have come in late, the question was raised as to whether the mark, the space, or somewhere in between, should be used to specify the frequency of a RTTY signal.

Edwin R. Ranson K5ER of Mustang, Oklahoma, writes: "The question of how to specify an amateur HF digital signal's frequency has been kicked around at least as long as I have been on digital modes, and that's since 1966. Back then, it was pretty standard to specify the mark tone as the operating frequency, but that was before the days of digital readouts and frequency counters becoming so common. We were lucky to know our operating frequency within a kHz (in those days, a kHz was called a 'kc').

"I can tell you how the military and the NTIA (the Federal Government's equivalent of the FCC) specifies frequencies. It is the center frequency of the occupied spectrum. For example, for a voice upper sideband SSB emission, the assigned frequency would be 1.5 kHz above the (suppressed) carrier frequency, since the signal occupies the spectrum between the (suppressed) carrier frequency and the carrier plus the highest modulation frequency. (Voice bandwidth is considered 3.0 kHz wide.) So, if your carrier frequency is 14.300, the assigned operating frequency would be 14.3015. For CW, FM, and AM modes, the center of the occupied spectrum is the carrier frequency, so the assigned frequency and the carrier frequency would be one and the same.

"The same method is used for all emission types, including FSK modes. So, if your mark is on 14.070, that puts your space on 14.06983 (with a 170 Hz shift, with a low space frequency), and your operating frequency is 14.069915. What's the dial read on your transceiver? Depends on the scheme you are using, and, if you have a RTTY mode, the scheme the manufacturer used. Confusing? Not really for channelized operation. Figure it out once, program it in, (or order the right crystal) and you're there.

"But for the way we amateurs operate, that method leaves something to be desired. Personally, I think it makes more sense to specify the mark frequency as the "operating" frequency, because that's something you can measure with a counter. Since there are several different modulation schemes, the standard should be the lowest common denominator. Whatever we use, there should be some sore of standard, so when you want to find the station who said he would be on 14.074, there is an unambiguous understanding of what that number means."

Another opinion was proffered by Kit Kohlmoos W6ISO, whose work we have enjoyed as well in these pages. Kit writes, "I suggest that you consider what the FCC monitoring station will hear [to] determine the answer. When I am setting my frequency close to a band edge, I always calculate the extreme limit of my transmitted sideband in the direction of the band edge, then I set the transmitter frequency so that there is at least a 1 kHz guard band beyond the limits of my signal.

"It's obvious, therefore, that with AFSK the operator should center the indicated frequency about 4 kHz inside the lower band edge if the shift is down, and vice versa if [he's] near the upper band limit and shifting up."

As if not to be outdone, the August 1991 issue of *QST* carries an article on page 28, entitled "What Your Frequency Display Really Tells You." Covering much of what we have brought up, asked about, and speculated upon, this five-page article answers some questions, raises a few more, and fleshes out the topic nicely. It's good reading, and I recommend it to anyone who is interested.

On the flip side, Kit is looking for an "elementary cartridge and interface...to put a C-64 on RTTY, AMTOR, and CW." He's been running a Sinclair ZX81 with software by AF8J and a home-brew interface, but finds it subject to occasional strange tricks which he supposes are due to "RFI, punching the wrong key, or just the whims of nature."

A related question comes from J.R. Popkin-Clurman VE7YT of Ganges, B.C., who is another C-64 owner. He writes that he "... recently acquired a Commodore 64. I have had a Kantronics UTU a number of years, but have never tried to use it until now.

"I would greatly appreciate it if you will tell me how to marry the Commodore 64 and the UTU so I can use it for AMTOR. I am presently on RTTY using a 28KSR with an ST5000."

Segueing into AMTOR, a Mr. Felsenfeld from Yorktown, New York, is looking for some introductory texts and current newsletters on AMTOR.

For all these, I turn the floor open to you all. While I recall a number of simple cartridges and the like for the C-64 in years past, I have no idea if these are still available. A company called Microlog, located here in Maryland, produced one such device. I can find no trace of Micrologat present.

As to texts, I really know of no single source other than those reviewed in this column in the last few years. Readers (and authors) aware of such material are also invited to keep me posted on new developments in the field of published information.

Try a New Band

And finally, a proposal. David Ovad NP2H of Blairstown, New Jersey, writes that, "...in reading 'RTTY Loop' in the August issue of *73*, I find myself in full agreement with William Martin N7EU. I also have found little AMTOR activity on either 30 or 40 meters. I will sometimes call CQ many times on 30 meters especially, only to find no one is on the band. I know the band is open as I use it to log on to NØIA (APLINK) on 10.1405. When I do find a QSO, the other person is as surprised as I am to find activity.

"Maybe we should declare Thanksgiving weekend an HF digital 'Try a New Band' weekend. I say let's give 20 meters a little breathing room. With the sunspot cycle declining, 7 and 10 MHz will become more and more valuable, propagation-wise."

As they say, Dave, "Use it or lose it!" Our dear Wayne has been promoting wider band use for years. Maybe it's about time we listened to him.

More on tap for next month, including more software, and more input from you all. Keep me posted on your digital activities, and let me know what you think of a digital Thanksgiving. Drop me a note at the traditional mail address above, or CompuServe (75036,2501) or Delphi (MARCWA3AJR). I'll be listening!

HAM HELP

Your Bulletin Board

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full (8½" x 11") sheet of paper. You may also upload a listing as E-mail to Sysop to the 73 BBS /Hamhelp SIG. (2400 baud, 8 data bits, no parity, 1 stop bit. (603) 525-4438). Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters 1 or l, or even the number 7. Thank you for your cooperation.

The Commodore/Vic-20 Ham Radio User Group has software for trade. Shareware or public domain ham-radio-related software only. All disks are on 5¼" format. Donations to the library are welcome. Write to *Howard S. Bacon KC4CIQ, 213 Holly Ave., So. Pittsburg TN 37380.*

WANTED: Any kind of HF, UHF, or VHF radio equipment that you no longer need. This is needed to help get a now-defunct high school ham club back on the air. Please help by donating to *Roger Bacon H.S. Ham Club W8MTM, c/o Dan Gettelfinger N8NTL, 8623 Pringle Dr., Cincinnati OH 45231.* Thank you.

NEEDED: Manual/schematic for EICO 369 Sweep Generator. I will pay for the effort. *C. Chadwick N4GTX, PO Box 1381, Palatine IL 60078. (708) 358-3603.*

WANTED: Schematic for Drake Model 2C Receiver. I will pay copying and mailing costs. *Larry Keith KF8BX, 4251 Meadowsweet Dr., Dayton OH 45424. (513) 233-1148.*

My husband is in the Air Force so I am studying for my Novice license while stationed in the Netherlands. I'm a complete beginner and would appreciate a "ham radio pen pal" to help me along. *Mrs. Suzanne Dickerson, 32CSG, PSC 75 Box 1726, APO AE 09719.*

Pastor of small country church desires to communicate with missionaries in Brazil and Mexico, but is on a limited budget. If you have an older HF rig gathering dust, can you help? Contact *Pastor Michael Crowell N5UJA, 4510 FM 1954-Rt. 6, Wichita Falls TX 76301. (817) 322-4606.*

Any MILITARY/DOD active or retired Hams wishing information on operations in Germany, (frequencies, equipment, license requirements, etc.) send SASE to *Robert Dickson Ret., PSC 1 Box R-4988, APO AE 09009-4988.*

Members of the Oregon Region Relay Council continue their drive for funds, to donate a fully operational 2m repeater to the Khabarovsk Amateur Radio operators of the Soviet Union. The Khabarovsk area of the Soviet Union does not currently have any repeaters. Please send donations to *Oregon Region Relay Council Inc., P.O. Box 25451, Portland OR 97225-0451.*

I would like to be in contact with other hams who enjoy on-going role-playing games. If you are interested in joining, write me and let's set up a sked. *Doug Brown KC4RSL, Rt. 4, Box 538, Commerce GA 30529.*

WANTED: A copy of the manual for the Heath SB-630 Station Console. *Bob Schlegel N7BH, 2302 286 St. E., Roy WA 98580.*

I would like to purchase copies of *Popular Electronics* and *Electronics Illustrated* magazines which were published between 1963 and 1983; also schematic/data on a Royce Model I-406 H-T 5W transceiver (manufactured Apr. 1977). Thank you. *R.E. Cassels KA5JTX, P.O. Box 11, Aloka OK 74525.*

I am requesting an operator's manual for the Yaesu FT-209RH 2-meter. I will pay copy and postage costs. Thank you. *Vicente Lopez NP4MZ, 60 Moore St.-5J, Brooklyn NY 11206.*

EROC, the Environmental Radio Operator's Coalition, has started a net on 14.330 MHz every Saturday at 1900Z. The EROC net is designed to promote goodwill between amateurs and to promote environmental awareness through the friendly discussion of topics. This net also handles traffic. Please join us in a cause worthy of amateur radio's use. If you are interested in helping the EROC directly, write the net manager, *Greg Beaver N8LAI, 184 Maplewood Dr., East Lansing MI 48823, or call (517) 351-7785.*

WANTED: Schematics only, for Galaxy GT-550, and/or power supply AC-400 and RV550 VFO. I will pay for copying and postage. *Stephen Brzoska N2MHQ, 27 Willow St., Washington NJ 07882.*

I am requesting an operator's manual for the Yaesu FT-209RH 2 meter. I will pay copy and postage costs. Thank you. *Vincent Lopez NP4MZ, 60 Moore St., 5J, Brooklyn NY 11206*

HW-9 Thump Suppressers

The mail has been running heavy lately since the word has gotten out the HW-9 is no more. Take it from me, if you hear of or get a catalog in the mail from Heath with the HW-9 listed for sale, they're all gone. What units Heath did have were sold at the Dayton Hamvention in no time. If you're lucky enough to have an HW-9, we might as well do a little bit of fix up work on it.

When the HW-9 goes to transmit, the audio line is shorted to ground via Q303, resulting in a rather loud thump. Jack Lau KH6CP has a simple and easy fix to suppress this thump. He just added a JFET in series with the audio line. Instead of grounding the audio, he opens it up. A lot of HW-9s have Zack's thump suppresser installed.

Another version of the thump suppresser comes from Paul Levesque KB1MJ. Instead of using a JFET to open the audio line, Paul used a 4066 CMOS chip (see Figure 1). This chip has several switches inside. By wiring up the different switches, he mutes the audio while at the same time creating an opening in the audio line. This chip also eliminates the thump from the HW-9's audio. See the schematic for more details.

Bandwidth Improvement

Paul has also improved the HW-9's excessive bandwidth. He writes:

"Perhaps the most annoying fault in the Heath HW-9 is its excessive 3 kHz bandwidth and the desensitizing of the receiver via AGC driven by strong signals in the passband.

"I've been quite successful with the 400 Hz, 3-pole crystal filter suggested by Wes Hayward when driven with a high gain FET in order to simplify the required changes. I can now operate on 40 meters at night, a feat found to be impossible with the original design. See Figure 2.

"I have purchased a small quantity of crystals and have matched them very closely in sets of three in order to provide optimum filter performance. Three crystals and the two 680 pF capacitors I have mounted to a small PC board create a 'drop-in replacement' for the original Heath filter FL301. A high gain FET from the J308 family provides a direct substitute for Q301, and increases the IF gain. A small toroidal transformer established the impedance match between the FET and the input of the crystal filter.

"I can provide a limited number of complete parts kits with step-by-step instructions for this conversion to the HW-9 users who are interested in improving the selectivity and AGC function of their transceivers. Keep in mind you'll forfeit the ability to copy SSB with this modification. The cost of the kit is $26. Write me a note if you are interested in more details. Should the demand exceed my supply, orders will be honored in the order received." Write Paul Levesque KB1MJ at 14 Wesley Street, Dedham MA 02026. Don't send your letters to me; route them to Paul for the filter modification.

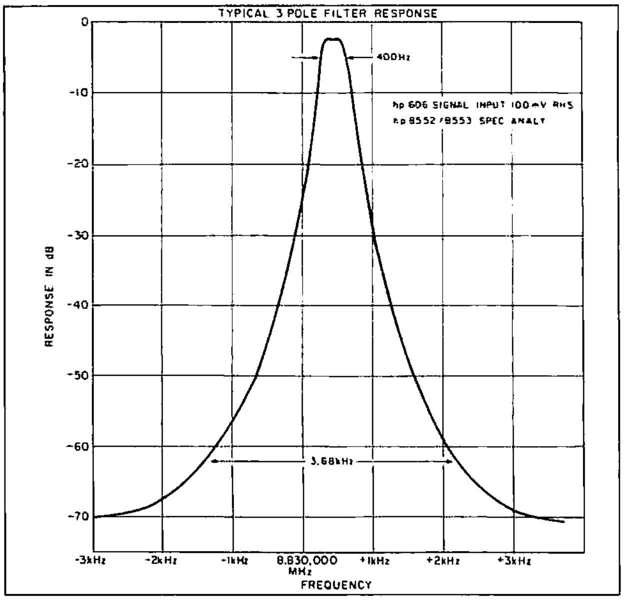

Figure 2. The audio response with the KB1MJ crystal filter circuit.

Calming the Transmitter

I've received several letters and even some phone calls about transmitter instability in the HW-9. There is really no one fix, but rather several fixes that *might* cure the instability. Some HW-9s, like the one I owned, exhibit no instability. I think some cases of instability may be traced back to how the rig was assembled.

When there is instability, it seems to occur mostly on the 15 and 10 meter bands. Adjusting the drive above 3 watts on 10 meters will slam the meter all the way over. This is a good indication of instability. If you have a high SWR on a resonant antenna, but a good SWR into a dummy load, you've got instability problems, too.

Several fixes may help you calm down your HW-9. First, re-solder the PA components as close to the board as possible. Excess lead length will cause problems. Also, change Q402 to a 2N4401 transistor. Since the circuit seems to be quite sensitive to transistor parameters, more than one might have to be tried. In real stubborn cases, try changing C434 to a slightly smaller value. Check the temperature of the PA's heat sinks. If one is really hot, and the other is cold, you might have one dead final transistor. This makes the other one work harder, upsets the design parameters of the PA stage, and results in transmitter instability. Both heat sinks should be comfortably warm after a five minute QSO.

The driver stage, Q404, uses inverse feedback in the form of R414 and C432. To reduce the drive, decrease the value of R414. Go down in small amounts; you don't want to reduce the drive to the point of reducing the power output. These "fixes" should calm down the HW-9's transmitter.

Looking for Trouble

Now, what about the HW-9 that will only put out one watt? Try inserting an ammeter in series with the supply leads. If the input current is excessive, with little RF being produced, your best bet is to start looking at diode D407 for the source of the trouble. If the diode goes bad, almost all of the power from the transmitter goes to transformer T404. Nothing bad happens, but you'll only see a watt or two on any of the bands.

Some of the modifications you may have done to improve the sensitivity of the HW-9's receiver call for replacing the diodes in the front end T/R switching scheme. The diodes are low power Shottky diodes. If you have replaced D407 with the Shottky diode or the recommended HP 5082-2835 diodes, D407 will fail. Diode D407 requires at least a 50 volt rating. There's a lot of RF across it during transmit.

Since Heath has dropped the entire line of ham kits, many of you have written to me, asking for schematics for the HW-7, HW-8, and the HW-9. Heath will still sell you a copy of the HW-7 manual for $17.50. Manuals for the rest of the QRP rigs should also be available. I don't know about parts. Heath tells me they only stock parts for five years after production ends. Call Heath for more details if you're looking for parts.

I have about 200 copies left of the *Hot Water Handbook* (containing modifications for the Heath HW series of rigs). After they're gone, that's it! There'll be no more printed. If you want a copy, send $8.95 to me, Mike Bryce WB8VGE, at the above address.

Since we have covered both the HW-8 and the HW-9, pick up one at the hamfest. They're a lot of fun to fix and modify, and with the days growing shorter, tinkering is especially fun.

Never Say Die *Continued from page 4*

the technology of the information age. Yet I feel I'm getting nowhere in helping this desperately needed growth. We're seeing a spurt now as a result of the no-code license, but I had to fight the ARRL for that damned thing for 30 years. Heck, we wouldn't have a Novice license now if it hadn't been for FCC Commissioner George Sterling W1AE jamming it down the ARRL throats.

Once you understand how our American system works, it's easy to make money. Pathetically easy. And, at the same time, you can do things which need to be done to improve the world. I've been working on improving amateur radio and, my ego says, having occasional successes. I'm working to improve the music, the publishing, and the educational businesses.

When you work smart you have time to play too, so it being apple season right now, I'm spending a couple hours a day canning my homemade applesauce. . .the best in the world. You know, I should plant a whole orchard of Golden Transparent apples and go into the business of making this applesauce. There's nothing like it at any price, and it lasts perfectly for years when you freeze it. If you stop by and say hello, I'll give you a taste and completely ruin your acceptance of canned applesauce for life. Hmmm, let's see. . . if each tree will make about 300 quarts every two years. . . .

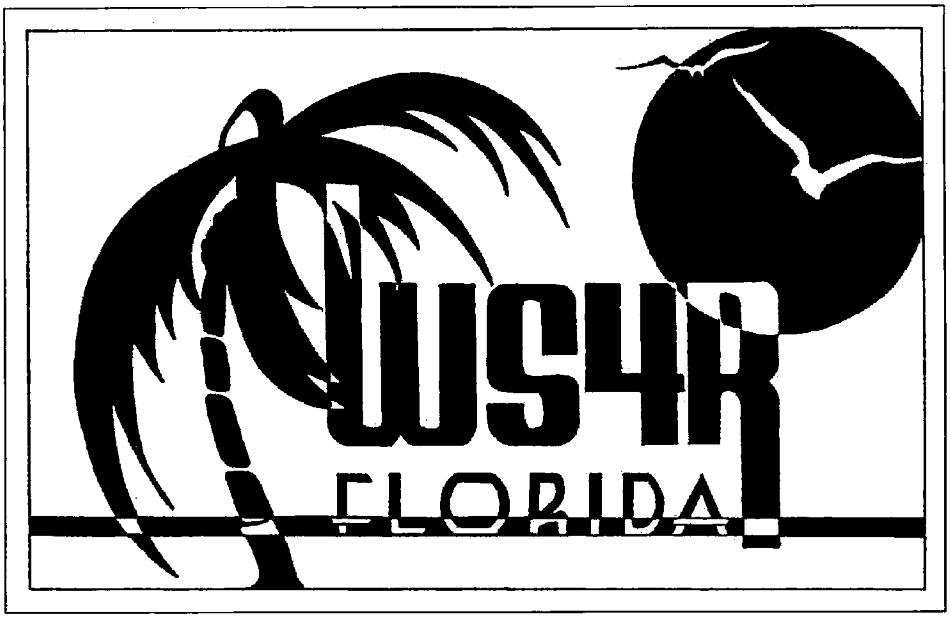
No, I've got to stop coming up with new business ideas. Did I tell you about my "Hurry Curry" business? Probably not, since someone would surely make zillions with it, and all I'd get would be a 1% chance at gratitude. That's a good one to save for my old age.

Tell you what: If you'd like to take off a few days and talk with me about building amateur radio, making money, and such trivia, you're invited to attend the 16th Annual Winter Ham Colloquium in Aspen, February 1–8. We'll ski during the day, HTs in hand, in order to clear our minds for the strenuous evening dinner conferences. Just be there and check in on the local repeater for conference details. Chuck KO1I will lead the expert skiers. I'll be in charge of the aged and infirm who have to stick to the intermediate slopes. Just one more year and I get to ski free!

Shooting The Messenger

Having had a note from a reader about his frustrations in trying to get Bell Helicopters to correct a fault in the wiring harness of a new helicopter, I was interested to find that he'd been laid off. . . and that the V-22 he warned them about crashed on its maiden flight.

In talking with amateurs in government, the military, large corporations and educational institutions, I've found many (most) of them frustrated by poor management and waste. Their frustration eats at them because they hate to see things going wrong, but feel helpless to do anything about it. They know what happens to whistle-blowers, and it isn't pretty.



QSL of the Month To enter your QSL, mail it in an envelope to *73*, WGE Center, Forest Road, Hancock, NH 03449. Attn: QSL of the Month. Winners receive a one-year Subscription (or extension) to *73*. Entries not in envelopes cannot be accepted.

One enormous source of bureaucratic waste, for instance, is the frantic spending of allocated funds at the fiscal year end. Bureaucracies work on the basis of ever-increasing funding. They know if they don't spend everything allocated, their funding will be cut the next year. The people working in these bureaucracies understand the system, but they also hate it. No one likes to see money wasted. . .not even public money. The punishment of whistle-blowers enforces a conspiracy of silence.

I'm sure there were many people who knew what was going on with the savings and loans. . .and many well aware of the BCCI scams. They also saw what happened to the few people who were foolish enough to try and wave the red flag. The lucky ones just got fired.

I suppose you haven't bothered to read P.J. O'Rourke's recent *Parliament of Whores*, so you don't know what a fake the federal budget is, and how Congress is a willing part of this whole scam. (You've also probably heard of Parkinson's Law, but have you ever read his 1957 book? Great stuff!).

P.J. tells us that the emperor has no clothes, that the whole mess is baloney. He makes a solid case. And from the endless horror stories I've heard from hams working in the government and the military, P.J. is not exaggerating. One of the things I recommended as a way to help balance the budget was to set up a federal whistle-blowers protection program. . .perhaps relocating them just as they do helpful criminals. After all, to bureaucrats, whistle-blowers *are* criminals.

If President Bush ever gets more interested in solving our national problems than in curing those of Cyprus, this might be a good starting point. I doubt there is a government agency other than the FCC that wouldn't be enormously improved by cutting its appropriation by 10% per year for the next ten years. That would cut them down to about 35% of what they get today, and it probably would all have to go to pay the generous government pensions. The drop in paperwork alone would allow millions of acres of Canadian forests to regrow.

And The Post Office

While we're cleaning up the mess in Washington, let's lean on congress to take away the monopoly from the post office. That'll put it out of its misery in short order. We might even start exchanging QSL cards again.

Private industry could do an infinitely better job at a fraction of the cost. Oldtimers can remember when we'd contact someone and automatically send them a QSL card. I'm old enough to remember the penny post card. Many of my old QSL cards have 3¢ stamps on them.

There used to be dozens of major QSL card printers. It was a nice business for a retired ham. All it took as a Kelsey press and a classified ad in a ham magazine. I've still got my old press out in the barn somewhere, complete with several large trays of type. Boy, that was fun!

Perhaps it's getting time to build fax modems into our transceivers so we can end contacts with faxed QSLs. We could fill in the "card" on our computers (any kind) with the call, report, and a short message. Anyone up to writing an article on the details? Yep, it'll be black and white for now, but color printers are getting cheaper, so we'll eventually be able to swap full color QSLs. That'll save us about 30¢ on local QSLs and much more on DX QSLs. I can see the day coming when we'll be able to work all continents in ten minutes and have the QSL cards in hand to prove it.

Yes, I hear you old grouches grumbling about the cheats. Look, fogies, we've always had cheats. So what? I've been issuing DX awards for over 35 years, so I've seen the lengths some hams will go to. Weird.

I'm already on record as favoring limiting DX credit just to contest weekends. Then we can ask the rarer DX ops to send in disks with their logs and let a computer sort it all out. We're not worried about the 200 easy countries, just the 200 hard ones. I predict that the ARRL will be set up to handle DXCC disk logs about 12 years after we lose our last DX band.

The Rescue

During the freshman year in many colleges, the fraternities invite you over to meet them. . . and to see if they want you as a pledge. This is called "rushing." I visited a bunch, looking for one where I might fit in. The Dekes had a well-earned reputation for being drunks. The Alphas were snobbish rich kids. . . even had their own bowling alley in their frat house. And so it went until I got rushed by Phi Ep. They seemed more my style, so I pledged.

The freshmen all lived in the freshmen dorms the first year. Then those who didn't make it into a fraternity moved to the upper-class dorms. The students separated into the Greeks and the Geeks.

My prospective fraternity brothers loved the hazing, making life miserable for us pledges. This consisted of making us uncomfortable psychologically and physically. For instance I was given about ten minutes to learn the Greek alphabet, interspersed with a good deal of "assume the position," which was followed by all the batting strength our best ball players could muster. I still know the Greek alphabet.

I suspect that if ham clubs would apply this system to new members to get

them to learn the code we'd solve that problem.

One standard hazing routine was to take the pledges out and get them lost. So about one in the morning one cold snowy night four of us were blindfolded and driven for about a half hour and then two of us were dropped off on a back country road. The car drove off with the other two, leaving us in the snow, with no hint as to which way to walk. There wasn't even a glow in the sky to head for. Worse, there weren't even any other tire tracks in the snow to suggest that more cars might come along. We sighed and started walking.

About five minutes later we saw the lights of an approaching car! At this time of night they'd never stop, but as it zipped by we tried to flag it down. It skidded to a stop and a voice shouted back, "Hey Wayne, is that you?" It was Car-mine Mirenda W2MAM, from the next fraternity down the street from ours.

Carmine dumped out his two pledges and picked us up. It turned out that this was a popular pledge dumping spot. My fellow pledge and I earned an extra beating for getting back to the fraternity house before the brothers who had dumped us. No, we never explained how we did it, but we sure had the laugh on them. Our other two pledges dragged themselves in the next afternoon. If Carmine hadn't recognized me we'd have gotten back around the same time.

Though Phi Ep was in an old beat-up brownstone house in a crummy section of town, and it was about the only non-national fraternity, I didn't mind. I found I'd picked well when the next year we won the intrafraternity sports trophy, the intrafraternity scholarship trophy, and got our president elected the Grand Marshal of the school. We capped that by buying the ex-governor's mansion, moving to the most exclusive part of town, and becoming a Sigma Chi chapter.

I'm afraid my grades didn't help us with the scholarship trophy, and my bowling (195) as third man on the team wasn't a big boost toward the sports trophy, but my modulator powered one heck of a public address system, filling the campus with hi-fi sound and election propaganda.

It had been tough putting up antennas in the brownstone row of houses, but in the new house there was enough room for me to put up *two* 20 meter Twin-Three beams. I worked out like a bandit. I had both a 75m kilowatt (203Zs) and an all-band kilowatt (813s). I put out a humongous signal on all bands. Those homemade W8JK Twin-Three beams were killers.

Alas, Carmine, who weighed in at around 400 pounds, not surprisingly won the coveted Silent Key award while he was still quite young.

Is No-Code Working?

Yep, so far. Looking at the new license figures from the FCC for the February–June period, I see that 1989 went up 2% over 1988, 1990 went up 9%, and 1991 is up 56%. That's a big jump. May was up over 100% from last year. Will it last? The mail I'm getting from clubs around the country is encouraging.

Clubs are reporting substantial increases in their licensing classes. Getting 'em to send me pictures to prove it, is harder than getting 'em to organize group subscriptions to the magazine. Despite almost every family in America having a camera, getting club pictures of ham classes has so far turned out to be a bust.

I'm getting two kinds of letters about no-code. One is from old-timers who are still convinced that no-coders will turn our bands into CB-like messes. The other letters are from readers who have been in contact with these new licensees and are impressed by what good operators they are.

I'm also getting stacks of letters from no-coders thanking me for helping make their license possible. And every one of them has mentioned that now they're working on the code so they can get their Novice and get on 10m . . . and then their General. The letters from the old-timers who are still living in their dream (nightmare) world and who have made no effort to check what's actually happening are in wonderful contrast to the others.

I'm hearing from more and more clubs with license classes filling up. Who knows, this enthusiasm may not be a temporary blip. But we still have a long way to go before we're anywhere near the growth we had from 1946–1964, before the ARRL's "Incentive Licensing" debacle killed the American radio industry.

Now we have an answer for the kids who argue that the code is a useless relic of the past. No problem; get your ticket and join the fun on 2m and up. It gives us a little easier "sell" to youngsters who turn up on CB and find it frustrating.

Has your club appointed some hunters to prowl 11m, looking for new meat? CB is prime hunting ground for potential hams, but you have to catch 'em quick, before they get fed up and quit.

One more thing. Let's not inculcate these newcomers to 2m with the really rotten things some old-timers have almost developed into an art form. Like not answering when a newcomer calls in on the repeater.

Let's see, where was I the other day? Oh yes, New York. I was way up high in the Empire Hotel by Lincoln Center and was able to kerchunk a dozen repeaters. I gave my call and asked if anyone was listening. I got answers on two repeaters. Two! One was in New Jersey. And no, no one was avoiding me. I don't think anyone ever gets my call right the first time . . . and few hams recognize it even when they do finally get it. Maybe 10% put W2NSD and WG together.

Look here, this is a hobby with all of us fraternity brothers, so let's be friendly, helpful and make hamming fun. I really hate it when I need to get word through that I'm going to be late to meet a friend for dinner, only to get refused by hams and have to ask CBers to get help . . . which they cheerfully do. I'll bet I won't get turned down by a no-coder . . . unless some bozo gets to 'em first and louses up their head.

New National Park Proposed

The inside word is that the League directors are considering submitting a proposal to the FCC which would set aside the upper half of the 75m phone band as an Old Hams' Home . . . a retirement community made up of retired hams who are too unskilled, too lazy, or too poor to spend what's left of their unproductive lives playing golf.

Theirs is a force which some directors feel should be harnessed. There's even been talk of establishing special teaching channels along the edge of the Old Hams' Home where they would be able to instruct ham newcomers on proper language . . . with guest lecturers imported from 14,313.

Baxter K1MAN may be asked to prepare tapes for 24-hour-a-day broadcasting on a reserved channel, with endless readings from the current issues of *QST* . . . including all the ads. Baxter's great experience in non-stop broadcasting on the ham bands makes him eminently qualified for this service.

I understand that Dick Bash may be available to teach youngsters how to pass the 20 wpm code test without any knowledge of Morse whatever. And a special channel is proposed for making deals with VECs for mail-order exams so all certifiable Old Hams can get their Extra Class tickets without being overcharged.

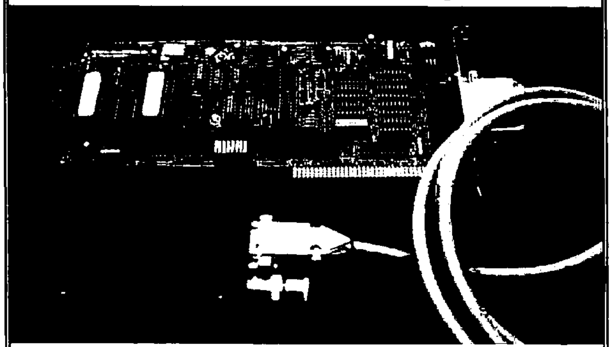
The unfortunate FCC clampdown on the KP4 license mill has forced ticket prices beyond the reach of many old-timers. Extra Class, which used to go for only $100 is now more like $500, which is still a bargain for the top-of-the-line license . . . hassle-free. Advanced seem to be going for around $250. And no, don't bother writing me to find out where to buy your license.

Special net channels and times will be established and enforced for the discussion of no-code, CBers, space cadets, lids, K1MAN, KV4FZ, AM, women, homosexuals, blacks, atheists, Japs, A-rabs, DX lists, contests, net jamming, etc.

Facing reality, the directors are said to be favoring a 10 kW power limit for this National Park Band. Since some of them already qualify to operate in the band, perhaps they don't want to have to operate just with their exciters to be legal. Seems reasonable to me.

Please send your comments to K1ZZ, ARRL, Newington CT 06111 . . with a copy to me. 73

the PackeTwin™ System



The PackeTwin data radio system, with integrated 9600 bps radio modem (G3RUH/K9NG compatible) and a 440 Mhz radio (*antenna* not included).

The PackeTwin is a high performance, dual-channel, sync/async PC interface card for data radio systems, with TCP/IP and AX.25 software (executable and driver sources provided.) Speeds of 1200 to 1 Mb/sec operation utilizing full duplex DMA. RS-422, RS-232, and TTL. The PackeTwin data radio is a single channel, crystal controlled unit delivering 2 watts output available in the 430-450 Mhz and 450-470 Mhz frequency ranges.

More Parts

Last month, we were discussing parts and how to manage them. Let's finish it up:

Keep Chippin' Away

Along with digital chips, analog or "linear" ICs also abound. For instance, most walkies today make use of the LM386 chip for their audio output sections. In some, a "real" LM386 is used, while in others, smaller versions and surface-mount chips with the same internal construction are employed. As with the digital chips, the ammended part numbers may obscure the generic type. For instance, the Kenwood TH-77A dual-band walkie uses the NJM386BM, while the Yaesu FT-411 has the NJM386D. The Kenwood also uses a couple of TC4066BF chips, which are just common 4066B analog switches, although they may be surface-mount mini chips (I haven't opened the rig to find out).

Also found are plenty of op amps. These, too, often have common numbers embedded in their designators. In any case, *any* time you want to replace a chip with one you think is essentially the same, be sure to compare the schematics for the pinouts first. Even if the chips do turn out to be functionally identical, there can be different pinouts, particularly when package types are different.

What Has Three Legs and Amplifies?

While there are lots of chips in our gear, many other semiconductors are used as well. Obviously, one of the most important is the transistor. Perhaps no other category of part has as many types as does the three-legged beast. I can't begin to cover them all here, but I'll try to touch on the major kinds.

Bipolar, or "common," NPN and PNP transistors are still the most often used. They can be found in just about any part of a radio's circuitry, from the front end to the audio amp. Nearly all voltage regulators, RF output stages and discrete audio output amps are made from bipolar transistors. The standard three-legged diagram with the diagonal leads and the arrow is the giveaway. If the arrow points out, the part is NPN; if it points in, it is PNP. What does this mean? It refers to the polarity properties of the internal semiconducting layers, and the shorthand gives you a clue as to which polarities must be applied to make the device turn on. To make an NPN transistor turn on, the base (which is the "P" in NPN) must be positive with respect to the emitter. To turn on a PNP, the base must be negative with respect to the emitter. Note that it doesn't matter what the "actual" polarity (with respect to circuit ground) is; only the emitter is used as a reference. Thus, a PNP transistor can be used in a positive-voltage circuit, with its base being pulled lower (less positive) than its emitter; that's the same thing as negative, as far as the transistor is concerned, and it will turn on.

Oops, I digressed a bit there, but for a reason. If you want to replace a bipolar transistor with one with a different part number (which is very often the case because there are so many kinds, and you can't get many of them), you must first narrow your choice to a part with the same polarity. You just can't replace an NPN with a PNP. By the way, the vast majority of transistors used today are NPN. PNPs, which are harder to make, are used only when really necessary, such as in push-pull (complementary) amplifiers and low-loss voltage regulators.

Besides polarity, the most important specs for bipolar transistors are cutoff frequency, gain, power dissipation and voltage breakdown rating. Whew, that's a lot! This would seem to suggest that it would be impossible to cross a transistor to another part but, in practice, it's done all the time. First, decide what the transistor is doing. If it's in an audio amp and is not part of a complementary pair (in other words, it doesn't have an opposite-polarity transistor connected on top of or below it), chances are that any similar part of similar power-handling characteristics will do the job. If it is part of a pair, you can still replace it with another kind of part as long as you replace its mate with the new part's mate. If you don't, you are likely to wind up with mismatched parts, which will cause signal distortion, uneven current distribution, overheating and premature part failure of either your new part or the old mate.

By the Numbers

A few words about Japanese transistor part numbers: most parts start with either 2N, 2SA, 2SB, 2SC or 2SD. 2SAs and 2SBs are PNP, while 2SCs and 2SDs are NPN. Many techs have been mystified by parts with numbers like "C945." It pays to know that the manufacturers often leave the 2S designator off the part to save space. So, a C945 is actually a 2SC945, which is a very common part. A number which starts with a "3" signifies an FET.

FETs

The FET (Field Effect Transistor) is an entirely different kind of transistor. It uses the "field effect" to regulate electron flow through an internal channel. Its leads have different names: Gate, Source and Drain (instead of Base, Emitter, and Collector).

The gate is analogous to a bipolar part's base, while the drain is like the collector, and the source is like the emitter. In some FETs, the drain and source may be interchanged while, in others, that is not possible. The diagrams look different, too.

In JFETs (junction FETs), the leads all exit straight, not diagonally, and the arrow is in the gate lead in the middle. The arrow points the "other way," too. P-channel FETs have outward-pointing arrows, while N-channel parts have them pointing inward.

In MOSFETs (which have no actual junction between the gate and other leads), the gate is shown as a line separate from and parallel to the one which joins the other leads. No matter what kind of FET you are working with, the important thing to remember is that, as with bipolar parts, you cannot replace a P type with an N type or vice versa. Also, you can't substitute JFETs and MOSFETs for each other.

Power FETs are similar to normal MOSFETs, only they are bigger and can handle much larger amounts of power, just like bipolar power transistors. They have the same basic characteristics as the smaller MOSFETs. They are just starting to find their way into our gear, but they are great parts and seldom fail unless badly overstressed. Their part numbers are very different, and may be something like "IRF511." If in doubt, look at the diagram. Needless to say, you can't replace an FET with a bipolar, or a bipolar with an FET. Their characteristics are just too different.

There are some other, obscure kinds of transistors. One that comes to mind is the unijunction transistor. This thing has a diagram that looks like a bipolar part, except that the base comes in at an angle. Unijunctions are used primarily as pulse generators and oscillators, but they are rare. I haven't seen one for a long time.

Look it Up

A great way to find a transistor substitute that will work is to get a transistor substitution book which lists the "generic" American parts, such as those by GE or RCA. Then, look up the part you want to replace and see what the generic replacement is. Now, look up the part you have available. If it is replaced by the same generic, it will probably work. Even if it isn't, you can look at the specs on the generics and see if they are similar. Beware, though: I have found errors in these books. In a few cases, a large heat-sinked power transistor was crossed to a tiny, milliwatt-level part. In such a case, common sense must prevail; don't try the replacement if you don't like smoke!

Walking on Two Legs

Two-legged semiconductors are usually much easier to substitute. Nearly all the two-legged beasts you will encounter are rectifying diodes. The ones that go bad are usually found in power supplies. In a normal, linear-regulated AC power supply, just about any diode of high enough voltage and current capacity will work fine. A common number would be 1N4002. By the way, those four-legged bridge diodes can be replaced with standard diodes wired to emulate them, again as long as the voltage and current ratings are adequate.

In switching supplies and regulators, high-speed diodes are used and the regular types just won't work. Your substitution book should cover most of these things.

Zener diodes are used as voltage regulating elements. Their diagram looks like that of a diode, except that there are slanted lines exiting from the central one. Zeners operate by breaking down in the reverse direction at a preset voltage. Their essential characteristics are the breakdown or "zener" voltage and the power dissipation capabilities. Nearly all the voltages can be had in generic parts, so it is usually not too hard to substitute zeners.

Small-signal switching diodes typically are of the 1N914 or 1N4148 variety. They are pretty much all interchangeable. Some low-noise switching diodes are used in transceivers, though. If you replace one with a standard diode, it probably will still work, but the circuit's performance may be degraded due to noise generated in the cheaper part. Manufacturers only spend extra for the low-noise diodes when they have to, so it pays to replace such a part with another low-noise one.

Varactor diodes are not really diodes in the rectifying sense, but they have two leads, hence the name. They are really voltage-variable capacitors and should be replaced with exact part numbers or parts with the same capacitance and sensitivity characteristics.

"Hot carrier" and other exotic diodes are sometimes used in mixers and the front ends of receivers, especially in the VHF-and-up range. For correct circuit performance, it is important to replace them with the same types.

Home-brewing

If you're building something from scratch, you may have great leeway in selecting which parts you'll use. In fact, if you have a well-stocked "junk box," you may find yourself designing your circuit to use what you have! This technique can save lots of time and money, but your gadget may not be easily reproducible by others, because those special parts you've been squirreling away since 1957 may have gone out of style. Especially if you want your device published, it pays to use as many standard parts as possible, and to avoid unavailable ones like the plague.

Playing the Standards

So just what constitutes "standard" parts? Well, 2N3904 and 2N3906 transistors are about the most common kind available in the USA. Ditto for 1N914 and 1N4148 switching diodes and 1N4000-series power rectifiers.

If you're designing a digital circuit that doesn't have to operate faster than a few megahertz, consider using 4000-series CMOS parts. They use very little power, do not require regulated power supplies, and are very available. All in all, they are much easier to work with than are TTL and LSTTL chips.

In op amps, the TL-072 and TL-074 are common, as are the 1458 and similar numbers. In voltage regulators, the three-terminal National parts, such as the LM317 and the LM340, are virtual standards.

Well, I promised the addresses of various parts sources but, alas, I'm out of space again. I'll have them all for you next month. See you then.

Freedom

By the time you read this, things will hopefully have calmed in the Soviet Union. As I write this, the right wing coup is less than 24 hours old. Gorbachev is under house arrest and has yet to surface. Yeltsin is defying the order to vacate his offices, has called for a general strike, and a warrant has been issued for his arrest. Tanks surround the Kremlin, and the world is waiting to see the response from the several republics that have recently tried to declare their independence from the Soviet Union.

As I watch the events in the Soviet Union unfold before me on my television, one word keeps coming to mind: Freedom.

The people of the Soviet Union have, for the first time in their long and tragic history, been served up a small taste from the plate of freedom. Will they be happy with the memory of this brief period of openness, or will they stand up en masse and declare to the power brokers of their society that they refuse to go back to the old ways of repression, fear and dictatorship?

By the time you read this the events will probably have run their course and the outcome will be apparent. For now, watching this giant nation struggle with itself from the comfort of my living room, all I can think of is that one word: Freedom.

Depending on how much of it you have, freedom means different things to different people. It can mean the freedom to speak your mind and criticize the government, without the risk of being thrown in prison. It can mean the right to publish or purchase a copy of Penthouse—or a copy of the Bible (in the U.S., the same article of the constitution covers both). It can mean the right to worship God in your own way, whatever your concept of God happens to be. It can mean the right to work for a fair wage, and that you will not be judged by the color of your skin, the religion you subscribe to, or your gender.

Freedom to a struggling farmer in a third world country may consist solely of being able to provide food and shelter for his family.

Here in the United States, we enjoy an abundant supply of freedom. Our laws of free speech and expression go so far as to allow us to take the symbol of our freedom, the flag, and publicly destroy it in protest. We can stand in front of the residence of our president and shout at him all day long. We can assemble by the hundreds of thousands in front of the Capitol building and express our outrage. Every few years, we have a quiet revolution—it's called election day. Whether it's a senatorial, congressional or presidential election, our system has been set up so that no person can remain in power without the consent of those who bestow that power—the people.

What has all this got to do with amateur radio? Plenty! What do you think it is that gives you the right to tune up on 40 meters and call CQ? What gives you the right to comment on a proposed rule change by the FCC? What gives you the right to tell your congressman that unless he supports a certain bill, he'll be looking for a new job after the next election?

The freedom we exercise every time we fire up the ol' rig is the same freedom that allows some to hang out on 75 meters every night and tell dirty jokes with their friends. The freedom that allows me to trade a recipe for alfredo sauce over packet is the same freedom that allows those screwballs on 14.313 to tie up that end of the 20 meter band with their endless banality, bigotry and bull. Every time we hit that push-to-talk switch, we are taking advantage of freedom.

As we all learned in high school social studies class, freedom carries with it responsibility. Have you ever really pondered what that means to us as amateur radio operators? Every time we transmit, we are giving evidence to how well we are handling the responsibility of some very powerful freedom. Are we exercising that freedom responsibly, thereby guaranteeing it for the next generation, or are we taking advantage of that freedom to serve our own ego?

I'm not advocating that all communication on the amateur bands needs to be dull. I love to get into intelligent discussions of politics and religion, as long as they don't decay into name calling and hurt feelings. I've listened in on—and participated in—some pretty lively QSOs about such topics as the Gulf War, no-code, President Bush's domestic policies (or lack thereof), the recession, the homeless, Islamic fundamentalism . . . the list is endless. Each of these conversations was a heated debate, conducted by people with strongly held ideas and opinions, yet they all respected the responsibility that the freedom of speech demands. They had respect for the fact that they were choosing to exercise their freedom in a public place.

Whenever you transmit on an HF band, there is the likely possibility that you are being monitored by people in several countries. Each of these countries is different, with a different concept of freedom, yet most of these countries have a say in whether or not you and I, as radio amateurs, will be allowed to continue to exercise this freedom via radio waves. Are we showing, by our actions, that the free exchange of ideas, educational opportunities, and international goodwill offered by amateur radio is worth more to a developing nation than a shortwave broadcast allocation?

We do not have a right to the frequencies we occupy. Amateur radio is a privilege, not a right. It is a privilege that we, as a nation, have bestowed upon ourselves. A nation of 250 million has decided to let a group of less than 500,000 occupy some very valuable frequency spectrum. If the nation ever decides that our frequencies could be better utilized by some other service, we will lose those frequencies faster than you can say "majority rules."

Right now, radio amateurs have an enormous amount of freedom. Whether or not we can maintain it is totally up to us and how we exercise that freedom. What's going on in the Soviet Union this hot August night serves to remind us just how fragile that freedom is. 73

October is expected to be a very good month for propagation on short-path, long-path, and intermediate-path distances to DX locations. Although the solar flux continues to slowly decline, with occasional spurts to higher levels, the inexorable reduction in sunspots is going to take its toll.

Early darkness will tend to cause the bands higher than 14 MHz to close shortly before or after dark, while the bands below 14 MHz will begin to come alive for DX. Because of good opportunities for grayline DX (along the path of darkness), you can often make some excellent DX contacts shortly before or after dark and dawn, local time. Morning and afternoon DX will be great, however, from 14–30 MHz.

The best days for propagation will be more numerous than usual, with the really poor days concentrated around the 17th through the 22nd of the month. The appended chart will show you Good (G), Fair (F), and Poor (P) days, and those marked with two letters showing trends toward better or poorer conditions.

Those of you who enjoy DX on top band (160 meters), 80–75 meters, and 40–30 meters, will really enjoy October. During that season, the QRN levels decrease in the Northern Hemispehre due to fewer storms. There are fewer storms because of lower sun angles and less atmospheric heating and vertical mixing. Storm fronts may tend to be slower moving, but the tendency for prolonged high pressure areas to remain over large segments of the U.S. will prevail. VHF/UHFers should be sure to look for tropospheric ducting along weather fronts.

Keep a sharp lookout for some pretty harsh geophysical effects on the days indicated as poor. My guess is that the 18th, 19th, and 20th will be most critical this month. Batten down the hatches on those days, and look for us again in November. See you then. de W1XU 73

NEVER SAY DIE

Wayne Green W2NSD/1

Our Kids vs. Their Kids

If you've been reading *Business Week* you already know how American high school kids compare with the Japanese. It isn't comforting. For starters, the Japanese kids spend 60% more hours in school! And they spend an average of 19 hours a week on their homework, as compared to 3.8 hours for American kids. Is it any wonder they're running circles around us in technology?

If you add the homework and class time and ignore outside reading, it would take American kids 22.3 years to equal 12 years of Japanese education! 10.3 years is quite a handicap. Now, about that reading. . .the Japanese spend almost three times as many hours reading as American kids, so they've got us there too.

Spending more money to solve problems such as increasing the hours kids are in school isn't the whole answer. Forcing them to spend 50% more hours getting a second-rate education doesn't make much sense. Oddly enough, there have been some intelligent studies aimed at finding out what's gone wrong with American education. . .and they've been published. Question: Have you bothered to read any of them?

Yes, sure you love your kids and you hope that somehow they'll do better than other kids. But do you care enough for them to actually take an interest in their education? Not many parents do. Do you care enough for them to try and keep them from getting leukemia by making sure that they're not being exposed to electromagnetic fields. . .either from a nearby power line or pole transformer, an electric blanket, etc.? Do you care enough about their long-term health to not smoke around them?

Are you helping to educate your kids or do you mainly train them not to bother you? The American educational system is a mess, but it's organized in such a way that you have a much better opportunity to do something about it than you might think.

Though education is compulsory, the federal government doesn't control it. It's more in the hands of state governments. . .and those hands are within your reach. . .if you can force yourself to be interested more than momentarily. I don't want to cut into your hamming time or your watching ball games on TV for anything as insignificant as your kid's education. . .upon which the whole rest of his or her life depends.

Like quitting smoking or dieting, it's infinitely easier to put it off than to decide to actually do something. I wrote a little about that a few months ago in "Oh Darn, My Kid's Gone Bad." I think that went in one eyeball and out the other. Maybe if you'll try reading my editorials with one eye shut?

How many hours a week do you read magazines and books which will increase your own knowledge. . .either oriented toward your business or your general education? Sixteen years of school gives you not much more than a foundation from which to start a lifetime of self-education.

I've recently been organizing my library. It's amazing how many books I've read over the last 50 years. Fills 40 six-foot bookcases. . .and that doesn't count another 50 cartons of books out in the barn. Plus two bookcases for cassettes, three for LPs and six for CDs. My house is beginning to fill up with bookcases! Okay, put me down as a braggart, if that makes you feel better, but I brought it up to show that I'm not asking you to do anything that I haven't done.

How do you feel about people who are making more money than you? Is it luck? Or have they worked harder or smarter. . .than you? Are you honestly doing the very best you possibly can at your work? Are you absolutely sure there aren't some books and magazines which might help you do better? How about some courses you might take to help?

And what about amateur radio? Are you trying to learn all you can or are you a glorified CB appliance operator with only a vague understanding of theory? How many of our amateur radio hobbies have you exposed yourself to so far? Each one is a learning experience, and as such can be exciting and rewarding. How well-worn are your ARRL and Radio Handbooks? Tsk!

If you have any kids, have you tried to open their eyes to new ideas and things they can learn? If your kids are over 10, have you interested 'em in amateur radio yet? Kids being naturally contrary, that takes some doing, but it's possible. . .if you're smarter than your kid. Look at it this way: When you want an OSCAR antenna installed on the roof, are you going to have to climb up there or can you con your kid into it?

Making contacts via OSCAR is a blast. It isn't easy, so you know you've done something when you get good at it. Or do you just call in on a 75m round table and that's it? Or fritter away your life adding to the frustrating pile-ups on DX stations?

Been on packet yet? How about RTTY? Do you even know how RTTY works? Okay, how many data bits per RTTY character? How many for ASCII? How about for digital audio? Five, eight, and 16. Can you explain what a parity bit is?

President Bush has been taking some media heat for spending almost all of his time on foreign affairs and ignoring our national problems. He's been much more vocal about getting Turkey and Greece to stop fussing over Cyprus than he has over our educational disaster, our still-escalating drug mess and worsening crime in America. Maybe we need more media event ineffectual task forces.

Even some Democrats have noticed the national leadership vacuum, though few have had the guts to say much about it. And none have come up with any practical solutions to our mounting problems. . .they just carp.

I did get a White House leaked preview of their "America 2000" educational proposal, which has been thrown up in the air for target practice. As proposed, it seems like another delicious pork barrel effort, with $1 million for a school in each congressional district. . .to be used to try and improve the school.

I'm not sure where the government is going to get the needed half billion or why, without some coordination, they expect to see much change in the school system. Considering how the money is going to be distributed, I'm sure our congressmen will find the money somewhere. . .or just go off budget again. We know the money will be gratefully received and happily spent. Perhaps they'll spend it on higher administration salaries. . .at least until it's gone.

Unless this is your first brush with one of my editorials, you know that I don't bring up problems unless I have a proposed solution. And I try to make them creative solutions. So then, how can we turn a half billion dollar pork project into something of lasting value? A silk purse?

Let's put this educational project into a familiar frame of reference so we can deal with it. Let's consider this as an enormous technical research project. Obviously we aren't going to make much progress if we have 535 researchers all going their own way without any communications between them.

Scientists achieve progress through communicating via scientific magazines. They research one aspect of their subject, write a paper that is subjected to peer review and is then published. This tends to weed out the flakes and keep science lurching ahead.

The "America 2000" project would make a whole lot more sense to me if the researchers had a peer review magazine to help tie them together. I've been trying to get Rensselaer Polytechnic Institute to let me help them start such a publication for several years. They've inched ahead, starting a Center for Investigating Undergraduate Education (CIUE), but that isn't likely to accomplish much without a publication dedicated to new educational technologies.

Yes, there's a teeny weeny tinge of self-interest involved. Just by accident it happens that I'm in a good position to provide such a publication at a fraction of the normal cost for starting a new magazine. It wouldn't take a big investment to get it going and into the black. There are hundreds of entrepreneurs out there with innovative products they'd like to have schools know about. Schools will be experimenting with computers, networks, video, audio, card readers and so on. . .and that means zillions of software programs to be evaluated. I think there'd be enough advertising to pay the freight.

With a well-done communications medium I think it would be possible to get good value from the half billion investment. Without it, I smell pork.

Your congressmen and senators are going to be very interested in getting the million for their schools, so it's unlikely there's going to be a great groundswell opposing this bonanza. Write to your representatives and explain that you're going to be watching to see if they spend the money right . . .and that without a communications medium to help guide the participating schools as part of the package the likelihood of anything positive happening is slight.

Sherry says I'm wasting my time since 90% of you don't even have a clue as to who is representing you in Washington. I think she's wrong. . .it's probably 80%. Well, I know my mine. . .like Senator Rudman. And he knows me too. I write him. I visit him when I get to Washington and discuss what's happening.

Our ex-congressman Judd Gregg is now the governor of New Hampshire

Handicap Exemption Clarified

Last December 1990 the FCC changed its policy against code waivers, exempting severely handicapped amateurs from the 13 and 20 wpm Morse code requirements. Recently, the FCC clarified the term "severe handicap" to mean "a disability that extends for more than 365 days after the certification." This announcement comes at a time when some amateurs are thought to be asking for exemptions for handicaps that do not interfere with telegraphy.

The beginning 5 wpm code requirement cannot be waived, since international agreement requires telegraphy knowledge for operation under 30 MHz. However, Volunteer Examiners (VEs) are required to "accommodate" severely handicapped examinees at the 5 wpm level—even to the point of accepting a sending test for code receiving, or just identification of all 43 characters.

The FCC, of course, does not make medical diagnoses. It will exempt disabled amateurs from the higher speed requirements on receipt of a doctor's documentation of the severe handicap. The FCC only permits medical doctors (M.D.s) and Doctors of Osteopathy (D.O.s) to certify an examinee for the waiver. The examinee must sign a release permitting disclosure to the FCC of medical information.

The handicap waiver has generated controversy in many areas. One of the latest has been over the definition of a qualified medical practitioner. The American Optometric Association thinks the FCC's definition is "arbitrary and capricious, and without plausible support in the rulemaking record." The AOA believes that optometrists should be included in the definition, too. The ARRL is concerned that some (nonham) physicians may not appreciate the importance or purpose of the waiver. And David B. Popkin W2CC of Englewood, New Jersey, noted that FCC rules do not require the handicap to be permanent. "A broken writing arm could result in a perfectly legal certification at the time, even though the individual will be cured in a short time." Popkin requested the FCC to issue a uniform criteria to physicians nationwide. In response, the FCC issued two pages of information, Fact Sheet PR-5000 Number 205, and added the 365-day requirement to the rules. The Fact Sheet does not list specific disabilities which qualify for the waiver.

Dennis C. Brown (callsign unknown) argues with the FCC that if demonstration of code skill is necessary to protect the public interest, then it should not be waived for any applicant; but if the public interest does not require proficiency in code, then there is no valid reason to maintain the requirement for any applicant.

Disabled amateurs who are upgrading from General Class are now objecting to having to obtain another original certification from a physician for each upgrade, and they contend that a Certificate of Successful Completion of Examination for Element 1(C) (the 20 wpm requirement) should not be subject to expiration. At present, Part 97.505 rules do not provide for CSCE credit beyond a 365-day limit. TNX *W5YI Report, Vol. 13, Issue #17.*

New IRCs

A new version of the International Reply Coupon (IRC) is now out. The new version states that it is redeemable for the minimum airmail postage to another country. The older version was redeemable for postage equal to the minimum *surface* postage.

In the U.S., post offices should exchange valid IRCs from other countries (stamped on the left) for 50 cents worth of stamps. IRCs continue to sell for 95 cents. In theory, U.S.-issued IRCs can be exchanged for the original purchase price (in the center) minus a one-cent handling charge. In practice, few post offices offer this option. If you run into problems redeeming IRCs, refer your postmaster to section 392 in the International Mail Manual.

If other countries follow the U.S. example, and exchange even the older version IRCs for current air mail postage, the practice of requiring more than a single IRC for return postage of a single QSL card should end. Any DXer who purchases the new version IRC should point out to the DX station that this IRC covers return airmail postage. Any DX station requesting more than one IRC would be charging for QSL cards, a possible violation of DXCC Rule 12(c). TNX *The DX Bulletin, Issue 602.*

PELTS Now Dead

The proposed Personal Emergency Locator Transmitter System (PELTS) had too many problems, the FCC says. The channels held in reserve for PELTS were released to Private Land Mobile Radio Service use last August after the FCC concluded that at this time PELTS could not adequately meet the public need for emergency communication in remote areas. Had PELTS succeeded, it would have used frequencies in the 220–222 MHz band.

In December 1989, in response to a petition filed by Kenneth Seymour KA7OSM, the FCC proposed PELTS for two reasons: emergency rescue and reduction of the illegal use of emergency locator transmitters and emergency location-indicating radio beacons. Seymour, a cellular telephone engineer in Beaverton, Oregon, had originally conceived of modifying the 70 MHz Radio Control Radio Service rules for assisting those in distress in remote areas.

The FCC sought input from organizations and individuals. Fifty parties, consisting of search-and-rescue (SAR) organizations, the Civil Air Patrol, local and state agencies, manufacturers, radio user organizations, and individuals, responded with comments, and eight filed reply comments.

After carefully reviewing the responses, the FCC's decision to reject PELTS was apparently based on two issues: the watch-and-response system for PELTS was not sufficiently developed, which would result in uneven usage and a lack of support for refining the new technology; and the legal trend of pursuing large damage suits would probably discourage individuals and organizations knowledgeable in search and rescue operations from participating in PELTS.

For now, people camping, hiking, mountain climbing, or living in remote areas will have to continue to rely on devices such as smoke flares, strobe lights, signal mirrors, and balloons to alert search-and-rescue teams of distress and the need for emergency intervention. The FCC is looking to the Interagency Committee on Search and Rescue (ICSAR) for guidance on future developments. TNX *Westlink Report, No. 608.*

Earthwinds Balloon

In mid-November, the Earthwinds around-the-world manned balloon flight will be launched from northeastern Ohio. As described in the March '91 ATV column, three balloonists will fly at 35,000 feet in a pressurized capsule as they circle the globe. Captain Larry Newman KB7JGM plans to operate from the balloon on 28.303 MHz throughout the mission. In addition, when he is occupied with other duties, there will be a CW or voice telemetry downlink on this frequency which will periodically relay the balloon's current latitude, longitude, altitude and ground speed. Since this is the same frequency that is used by the CQ All School's Net (the net meets every Tuesday and Thursday at 12:30–1:30 pm Eastern time), it's hoped that schools as well as hams worldwide can have a great time tracking the balloon's progress on its record-breaking non-stop flight.

While over the U.S., there will also be a live TV downlink from the capsule on 434 MHz (fast-scan ATV) as well as a 2m FM signal on 144.340 MHz.

LETTERS

From the Hamshack

Keith Littlejohn via 73 BBS You told us a while back that kids should be able to learn the code at 20 wpm as easy as learning 5 wpm.

We (Kyla N7JVA and I) have five kids, and the three big ones (8, 7, and 5) are getting interested in ham radio and want HF privileges. So where are the 20 wpm tapes for beginners?

This isn't a silly comment! All of the high-speed code tapes are for upgrading from slower speeds, not for starting from scratch.

20 wpm is 20 wpm, so what would be different about a tape for beginners?

As I've written in my editorials every few years, you sit down with a 20 wpm tape and start listening. It's a blur, right? Not quite. If you start listening, you'll hear an E when it goes by. Write down E every time you hear it. Then start listening for T, and write down both E and T as they go by. Next start listening for I, and so on through the alphabet. It's a cinch. In a few hours, you're copying all of the letters, numbers, and punctuation... and at 20 wpm. Beats the hell out of trying to gradually speed up.... Wayne

Jeffrey Viola, Jackson NJ I am a new subscriber to *73 Magazine*, and a wanna-be ham for about 25 years (I'm 36). Probably would have become one as a youngster, but neither my father nor anyone else would take time with a 10-year-old who loved to take apart walkie-talkies, radios, or any other electronic gadget. Over the past two years, I bought the *ARRL Handbook* and every old *QST* I could get my hands on, and have been teaching myself radio electronics. Was gonna go for my Novice (old style) CW ticket, but something held me back... perhaps it was the coma I slipped into listening to the local ham club weekly rag-chew on 2 meters.

When I heard the FCC was going to issue no-code tickets, I jumped for joy! After all, I'm currently employed by a major stock brokerage house as AVP of their communications dept. Talk about technology—we've been sending data via modems at 9,600 bps for a decade. I have one 18 GHz and 23 GHz microwave radios (digital!) linking our headquarters. The 23 GHz radio alone gives me 28 channels, each 1.544 MHz wide! When the big earthquake hit California two years ago, we talked to our people on cellular radiophones. I'm looking into hooking up our SUN workstations on RF or infrared LANS. And "you" wanted me to learn code? Give me a laptop PC hooked to microwave spread-spectrum radio!

The point of my letter is this, however: For all the editorial lip service, *QST*, *73* (yes, *73*), and other publications have given to the new no-code ticket, where are the articles for the potential no-code ham? Other than the one-shot, pat-on-the-back short articles last spring, I have not seen one article. If a computer literate kid picked up this issue of *73*, would he know he could get a ham ticket? I called the local ham club and asked about it, and got less info from them than from a reluctant witness at a Mafia trial....

I personally believe that everyone is afraid that 50 MHz+ will become CB-land. Where are, at least, the UHF articles? Why not get electronics/ham advertisers to put out a special no-code one-time magazine? Charge a few bucks and put it on the racks for one year? And let us know where to sign up to take the no-code??

Jeffrey, we've published quite a few VHF and UHF articles recently. Look for future issues which will show you ways to enter the exciting world of VHF/UHF without breaking the bank. By the way, the magazine you'd like to see is a reality... it's called Radio Fun, *and is now into it's third issue!.... Bill WB8ELK*

Richard Bovee KF8NT, Toledo OH It has been said that along with the influx of the new no-code Technician class amateurs will come new technology. Along with that influx will come new amateur organizations, each striving to be the best they can be, serve their community and better the communications in their area. This, of course, will mean more repeaters. Herein lies the problem: repeater coordination. Good luck! This is exactly the situation we have found ourselves in. We cannot seem to find a 2 meter frequency that can be coordinated. Paging through the repeater directory, I find in some instances, and not to my amazement, more than one repeater per band per individual/club.

Do you suppose the time is near when the FCC should restructure the assignment of repeater frequencies and allow only one frequency pair per band per individual/club?

Jeffrey C. Montgomery WB4WXD, Palestine TX Congratulations on having a fine magazine that attempts to tell it like it is in the amateur community. Mr. Green's columns make life interesting, to say the least, and is the first thing turned to every month. BUT, I have to disagree with a statement made regarding Morse code as it pertained to emergency communications. Mr. Green stated that he was not aware of an emergency situation where code was used in lieu of voice or other modes because of their inability to get through atmospheric conditions. I was personally involved in a situation that proved said value of the code to do just that.

On November 15, 1987, East Texas was hit by several tornados. Our town was particularly hard hit, and lost most of its local and all of its long-distance telephone service. The local ham community swung into action and set up command posts throughout the city. Connection was made to the evening NTs traffic net on 75m using SSB as the primary mode. Because of the static crashes on the air, voice operation was unintelligible. The operators on both ends switched to CW, and although difficult to copy, the traffic did get through that night. The next morning when conditions improved, the traffic was handled on 40m SSB. In all, over 400 pieces of traffic were handled from as far away as Australia. The code proved essential to our operation that first night. We used SSB and packet for the majority of the remaining Health and Welfare traffic.

I am an Extra class ham who has paid his dues to the 20 wpm deity, but I also support the no-code Technician for those who desire to go that route. I've seen some fine, new Techs who are valuable to the service. But I think the reported death of CW is premature. Let's not write off a mode of communication that has proved itself of great value over the years.

Darren Leno WD0EWJ Now that you've piqued my interest in microwaves and all the other things I haven't tried yet, I'd really enjoy seeing more articles on the subject. Take us beyond 10 GHz, and show us where to go to teach ourselves more.

I would also like to see an article that describes the mysterious modes that we hear about but never quite understand, like pulse modulation and spread spectrum. I think many of us don't understand what we are even allowed to do on these high frequencies, let alone how to do it.

Thanks to your badgering, I've become very interested in trying modes that are new to me. I'm saving to buy fast-scan TV equipment, and recently purchased an MFJ digital thingamajiggy so I can learn about ancient modes like AMTOR, RTTY, packet, and stuff. I know I'm 10–30 years behind the times, but better late than never. Moon bounce holds a big fascination for me, and I've been listening to their nets on 20 meters.

Hey, why don't we put a 24 GHz repeater on the moon?

As for your plea to get "good" hams on 20 meters, I went and bought an HF rig just for you. I absolutely cannot believe what I hear on 14.312 (or thereabouts). It makes you want to do something, like tell those guys off. But then, we become part of the problem. So what is the solution? If hams are going to be self-policing, let's give hams some police power.

Darren's Big Solution to the 20 Meter Fiasco: Any ham who has not incurred a violation may become a "Band Monitor" after receiving approval by a full vote of the VEC organizations. If there is any objection by any VEC, that person will not be eligible to become a Band Monitor, but may reapply after one year. There will be no less than 100 Band Monitors and no more than 200.

The specific qualifications for becoming a Band Monitor would be decided later, but this method would prevent any one group from monopolizing the policing function. Band Monitors are responsible for monitoring the bands and issuing "notices" for simple violations. If a ham is a frequent offender, or commits extremely disruptive actions, the Band Monitor complaint is referred to the Hearings Board with the evidence (tape recording).

The Hearings Board is made up of two hams appointed by each VEC. These hams would hear complaints brought by Band Monitors and would have the authority to dish out license suspensions of up to one year. Revocation would be a penalty that only the FCC, on the recommendation of the Hearings Board, would be able to implement.

I think hams need to give themselves some teeth, Wayne. The FCC already makes a provision to listen to the advice of frequency coordinators in disputes arising from repeater interference cases. Why not give the VECs a little more authority to regulate the hams they are licensing?

Howard Pomeroy KA1ZCY, Suffield CT One of the reasons I'm writing is to inform you that I finally passed my Novice CW and theory, and now, Wayne, I am a ham. My callsign is KA1ZCY, and I am so proud of it. My only regret is that my dear Mom and Dad weren't here to share my excitement with me.

73 is a fine journal, my only comment is I wish the "DX" column were a bit larger.

G. Eric Ferguson KA6USJ, Concord CA OK. You've finally done it!! I am now motivated to upgrade from Novice to Tech. I'm your 8th place winner in the Ham-It-Up Sweepstakes. Up till now, I have had many excuses to not upgrade. Lack of money, no place for an antenna, can't remember code, etc., well, you get the idea. Even my Commodore 64 was given to me, and now it's an orphan. I have never been on the air yet, and have had my license for around 10 years. I admit I was hoping to win an HF rig, but I think I'm really going to enjoy the 2m/440 rig. THANKS!!

Fran KG7NZ via 73 BBS I enjoy your magazine immensely. Never stop griping and grousing, it encourages the rest of us to consider other ideas and problems. I also look forward to logging some time on your BBS now that it is up and running.

The new BBS has been up and running full-time since the end of July. Everyone is welcome to browse through the ever-growing list of useful programs you can download. We now have over 1000 users! Feel free to give it a call at (603) 525-4438.... Bill WB8ELK

Voice ID on a Chip

Throw your voice with this versatile circuit.

by Bill Brown WB8ELK

Every so often a device appears on the market that really gets my attention. A company called Information Storage Devices (ISD) recently introduced an IC chip called the ISD1016. This little wonder is the equivalent of a tape recorder on a chip! It eliminates all of the analog-to-digital (and digital-to-analog) circuitry that was required in the past to store and play back voice messages.

One-Chip Voice Storage

This single IC contains a microphone preamplifier, storage circuitry and an audio amplifier. This means that you only need to add a microphone, a speaker and a couple of switches and you have a complete audio recorder and voice identifier. The ISD10XX series utilizes a storage technology similar to that of an EEPROM (Electrically Erasable Programmable Read Only Memory). You may have heard of EPROMs (Erasable Programmable Read Only Memory). You can write data into an EPROM, but it requires a dose of ultraviolet light to erase the memory. Data can be stored into an EEPROM, but it is easily erased with a voltage instead of UV light. This gives you a powerful storage device that can be used over and over again many thousands of times.

The amazing thing about this technology is that the memory is non-volatile. That means that you can remove all power from the IC, even take it out of its socket, and it will retain all of the data stored inside. For example, you could record your voice, set the ISD chip on a shelf for years, plug it back into your playback circuit, and your voice would still be there! One other advantage of this EEPROM technology is that the ISD device samples and stores the actual voltage levels (analog storage) of the recorded audio, resulting in a high-fidelity playback.

Audio Fun

Since most of the complicated digital circuitry is eliminated with this new IC, it's easy to build up some very interesting audio devices. You may have seen those talking key chains with a few canned phrases. Now you can build your own version (although somewhat larger) that talks in your OWN voice. It's quite a lot of fun to put one of these in your pocket, hit the playback button, and watch as people think you're a fantastic ventriloquist. Be careful what you record, it could get you into trouble if you hit the button accidentally! In its simplest form, you can use a voice storage unit as an electronic note pad. You could leave messages for your family and friends, which they could play back later. Add a few switches and a few more components and you have some very powerful audio aids for your hamshack!

Contest Microphone

If you've been in a contest or an event such as Field Day, you know that endlessly repeating *"CQ Field Day, this is..."* can wear you down after a while. Wouldn't it be great to have a device that sent this message out (in your own voice) with the push of a button? How about storing two messages on one chip? A voice identifier which can hold two (or more) additional messages, such as *"You're 5-alpha in New Hampshire,"* would really save those vocal chords. You would only need to speak into the microphone to acknowledge the other station's callsign.

How it Works

The ISD1016 IC chip can record and play back a 16-second message (their new ISD1020 chip can be substituted in the circuit and allows 20 seconds of recording, but at a reduced audio bandwidth). The folks at ISD added digital control to their IC, allowing you to select the starting point address of your message. With the appropriate circuitry, you could divide up this 16-second chip into 160 messages, although they would be only 0.1 second long. For our voice ID, we'll use just two of these address lines to divide our 16-second storage area into two 8-second messages. Note, however, that if you start recording your message at the beginning of the chip, you can use the whole 16 seconds for your message if you so desire.

Your voice is fed into the storage chip via a miniature electret microphone. Toggle switch S3 sets up the voice ID chip to either a record or playback mode. Push-button switch S1 (momentary contact) selects the message start address and activates a 555 timer which brings the 1016's Power Down (PD) and Chip Enable (CE) lines low to start the message number one playback. In a similar manner, switch S2 selects message number two. After each message is played back, pin 25 on the ISD1016 goes low (the end of message signal, or EOM). The voice ID circuit uses this to reset the 555 timer which puts the voice identifier IC into standby mode for extremely low current consumption (3 milliamps when using a voltage regulator, and 150 microamps without the regulator when using a 5 or 6-volt supply). *[Note: If you operate this circuit without the 7805 regulator, do not exceed 6 volts for a power source. If you go this route, substitute a 1N4001 (or equivalent) diode in place of the voltage regulator, as shown in the schematic in Figure 1.]*

To record, switch S3 bypasses the timer circuit and selects the Play/Record input on pin 27. This allows you to activate the ID chip, as long as you hold down on one of the message push-buttons.

The ISD chip was designed to function in a cascaded fashion with a number of ICs in series for extended recording time. When one chip overflows its storage area, it uses the EOM line to turn on the next IC in the cascade. In a single-chip application you need to reset the voice storage device to continue operation if it overflows. This is done by bringing the PD (power down)

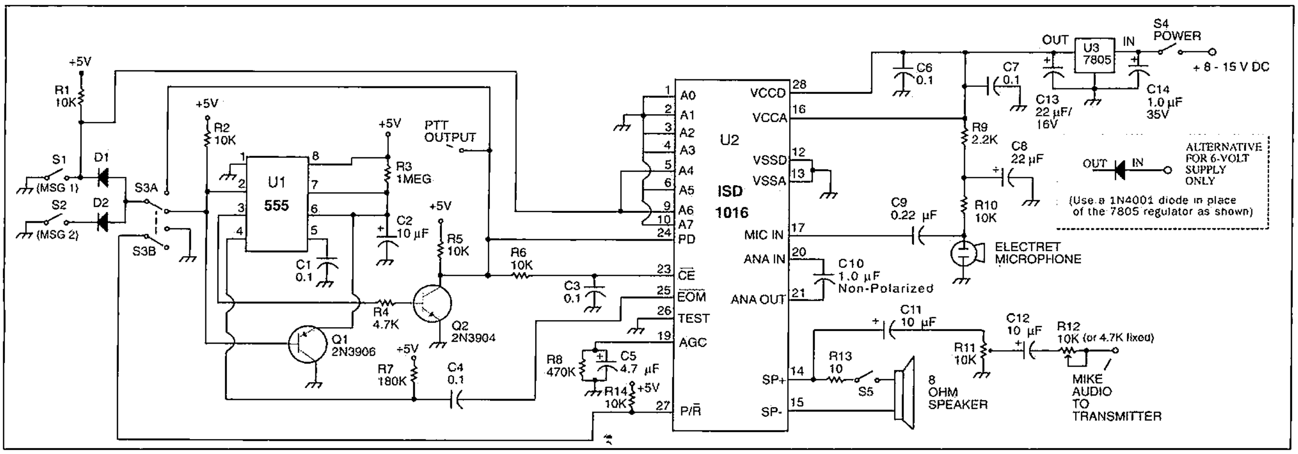

Figure 1. The voice ID schematic diagram.

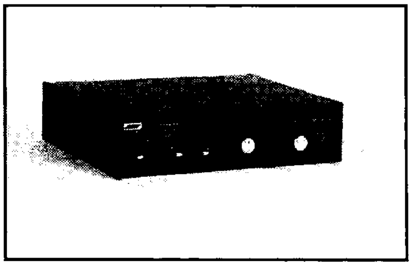
REVOLUTIONARY

is the only word to describe this:



The NIR-10 is a Noise/QRM Reducer for SSB VOICE! It is the only device available that can reduce noise and remove heterodynes occuring in the presence of speech. What makes this possible? Real-Time Digital Signal Processing (DSP) using a 40 MHz DSP chip!

•The NIR-10 is a DSP audio processor that connects to the audio output of your receiver or transceiver and includes a built-in Speaker Amplifier.

•Automatically Enhances Voice Reception by Reducing or Eliminating:
Heterodynes & Tune-Ups
White Noise
Ignition Noise
Power Line Noise
RTTY Interference
"Woodpecker"

•Includes a Bandpass Filter Mode to Enhance CW and RTTY. Forms a Variable Center Frequency Digital Filter with Selectable Bandwidth. Provides performance that analog filters can't match!

•Work More Stations: Allows Reception of Otherwise Unreadable Signals!

•Reduces Listener Fatigue.

• A Must for DXers, Contesters, and Field Day Ops.

Order direct:
NIR-10: $395; with 12V AC Adapter add $12. We pay shipping.

Orders 1-800-533-3819
Tech 1-919-790-1048
FAX 1-919-790-1456

MC/Visa. Allow 3 wks for personal checks. Add $3 for COD. NC residents add 5% sales tax.

JPS Communications, Inc.
5516 Old Wake Forest Road

Circle 285 on reader service card.

line high (which also puts it into the standby mode). The 555 timer IC also functions as a watchdog timer in case the 1016 doesn't get reset properly. If the voice storage chip goes into an overflow condition, the 555 timer will power it down after 20 seconds. Since the current drain is so low in standby, you can leave the voice ID on for long periods without worrying about your battery life.

The ISD chip interfaces directly to a small speaker. Our circuit taps off of the speaker output with two potentiometers, R11 and R12, which lower the audio signal output so that it can be used on your transceiver's microphone input (typically about 20 to 100 millivolts).

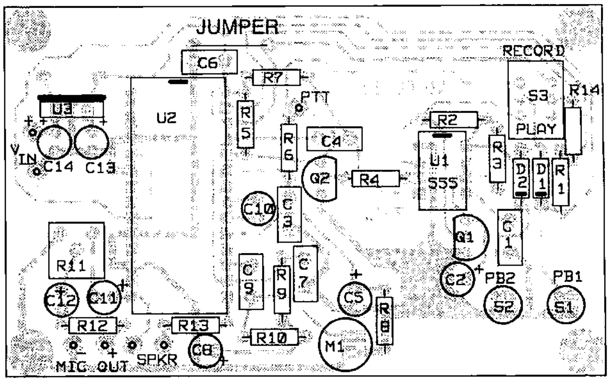

Figure 2. Parts placement overlay (viewed from component side).

Assembly

An etched and drilled printed circuit board (see the Parts List) is available which will make assembly of your voice ID easy. As an alternative, if you're used to breadboarding circuitry, everything should fit on one of the smaller prototype boards from Radio Shack. If you use the PC board, you can attach the push-button switches SI and S2, as well as S3 and the microphone, directly to the board. You only need to wire up a power switch, a battery pack and the speaker. If you want to interface the voice ID to your transceiver, you will have to wire up an appropriate microphone cable (the proper mike diagrams should be listed in your owner's manual). For a contest microphone application, you will have to make up a switch or relay to flip between the voice ID and your regular microphone (you can use the point marked PTT on the PC board and the schematic to trigger an automatic switch or relay when the board is talking). You may also be able to parallel the output of the voice ID across the audio input line on your rig's microphone plug.

If you use a Radio Shack project enclosure, you can mount everything inside (including the battery) to give you one very compact package. If you want to use a 9-volt battery or your shack's 13.8 volt supply, you should wire up the 7805 5-volt regulator (see the parts placement diagram and schematic). Your standby battery drain will be higher since the voltage draws a few milliamps in standby. For the ultimate in miniaturization, I use a tiny 6-volt single cell battery.

Operation

To record your message, just flip the *playback/record* switch to the "record" position, hold one of the *message* buttons down, and talk into the miniature electret microphone. As long as you hold down the *message* button, your voice will be recorded. If you want to record two messages, make sure you don't talk over eight seconds for each segment. Don't worry about filling up the whole eight seconds—the ISD1016 has a built-in *End Of Message* (EOM) indicator that tells it when the end of each message occurs. If you only record for two seconds, your playback will end in exactly two seconds. Note that if you exceed eight seconds for message number one, the EOM signal will not work and you'll run over into message number two. If this happens, you'll just have to try recording again. If you want just one message (up to 16 seconds long), record it into message one and ignore the message two button.

To play back your messages, flip the *playback/record* switch back to the *playback* position and hit the message button of your choice.

When using the audio output to drive your HF or VHF rig, adjust potentiometers R11 and R12 (start out with R12 at the mid-range positon) for the best quality output from your transmitter. If

Portable Frequency Counters

Versatile test equipment that you can really count on.

by Gordon West WB6NOA

Do you own a portable frequency counter? Every ham should have one. Even though you might not do your own internal adjustments to your equipment, a portable frequency counter is a valuable amateur radio accessory.

Here are some everyday ham radio situations where a portable frequency counter can really come in handy. Let's take a look at a typical day in the life of a counter.

RDFing

You can use your portable frequency counter to identify sources of radio frequency interference. This activity is also called radio direction finding, or sniffing. I used mine to pin down the problem of an electric garage door that mysteriously flew open at 5:00 p.m. every afternoon except on the weekends.

The counter registered 151.62500 as the door swung into action, and a quick check up and down the street revealed a utility truck with a high-band antenna on the roof. Sure enough, the driver's "at home, 10-7" transmissions at 5:00 p.m. were the cause of the door energizing. A couple of 0.01 microfarad bypass capacitors on the door opener solved the problem.

With some of the newer counters you can actually read the frequency of a 50 watt VHF mobile signal up to 250 feet away. With lower power HTs you can usually read their frequency from a couple of feet away (sometimes from across the room, depending on the sensitivity of the counter).

Do you own a cordless telephone? Trouble with interference from a neighbor? Since many people now own cordless phones, and there are only about 10 possible frequencies, you can resolve interference problems by first figuring out who's on what channel. Usually the channel number is marked on the phone, but that's the first thing to fall off after the cordless gets a cleaning.

Cordless phones only put out flea-powered signals. The counter is able to count out the transponder frequency, and the handset frequency, when held within a couple of inches of the phone's antenna system. Not only will you read out the precise frequency near 46 MHz or 49 MHz, but you can also tell whether or not your set is putting out the right amount of power. If you can read the frequency to within a couple of inches of the cordless phone's antenna, power output is normal. If you can't read the frequency with the antennas almost touching, your cordless phone probably has low batteries, or low power output. And once you know what frequency your neighbor's cordless phone is on, simply relocate your base unit further away from their particular direction.

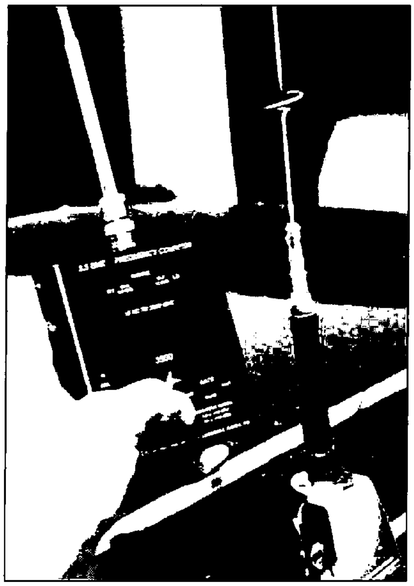

Photo A. To measure the output frequency of your mobile rig just place the counter near the antenna.

Fine-Tune your UHF Station

If you're into 1270 MHz repeaters, 1270 MHz mobile, and HT equipment, a portable counter can really help you fine-tune your sets. You see, equipment at 1270 MHz will many times "age" on frequency, and be as much as 2 or 3 kHz off-channel after a few months of operation. This is because the equipment may use a fundamental crystal still undergoing the aging process. When I checked out my 1282.4 MHz repeater system, I found that the repeater had aged up 3 kHz in just under a year, my handheld had aged down a whopping 6 kHz in six months, and my mobile unit was 2 kHz high.

Placing this equipment back on frequency is easy—hold the counter within a foot of the opened-up equipment, sample the frequency in the slowest rate, and adjust the trimmer capacitor to put the crystal right back on the money. How do you know which trimmer cap to adjust? It's the one usually in the same can as the crystal, and the technical manual for your equipment normally calls out the exact spot on the board. Use an insulated trimmer-cap wand, affectionately known in the land-mobile industry as the "twiddle stick." It's usually yellow with a tiny metal blade. CAUTION—MAKE SURE YOU ARE TURNING THE RIGHT TRIMMER, AND NEVER PRESS DOWN ON THE TRIMMER CAPACITOR. If you fracture the insulating material, you are in big trouble!

Calibrating Your Counter

But how do you know your counter is calibrated? Most counter manuals merely read, "To calibrate the counter, measure a stable signal of known frequency." Hey, wait a

High Performance Software by WA7RAI

QUICKYAGI II $40.00

• 100% computer-designed yagis for non-tech users. • Auto optimizer; optimum gain, F/B & bandwidth. • Auto/ manual modes. • 2 - 12 elements to 500 mhz. • Fastest analyzer available; calculates gain, F/B, and impedances in seconds (instantly w/math co-proc.). • Log or linear el. & az. polar plots w/ beamwidth. • Easiest to use of all yagi modeling programs. • Accuracy verified. • ARRL lab tested. • Includes 2 versions; for math co-proc. & no math co-proc. • Req. 360k & Hercules, CGA, EGA, or VGA graphics.

These util. are incl. in all "PLUS" pgms:
• 4 prog. time-zone clocks. • 200 yr calendar. • 10 min QSO timer. • Programmable log timer • DXCC d-base w/ beam-head. • Notepad w/ auto date reminder.

These features are in all Log pgms:
• Prints mailing labels & batch QSL reports • Scrolling log display w/ spreadsheet type data entry. • Hot keys. • Prog. auto entries. • Search/modify files. • QSL tracking. • Personal D-base. • Auto prefix/call/country/state search. • QSL tracking. • On-screen help. • Search/sort/modify all calls

The following are in all "X" pgms:
• Kenwood Tx/Rx control & display.*

The following are in all "II" pgms:
• Integrated auto-key plus program. • Iambic compat. paddle key etc. • 9 prog. TX buffers etc. • Hardware included. • Standard and Farnsworth rates.

AUTOLOG PLUS $25.00
AUTOLOG PLUS-X $35.00
AUTOLOG PLUS II $45.00
AUTOLOG PLUS II-X ... $55.00
AUTOKEY PLUS $30.00
AUTOKEY PLUS-X $45.00
QSO MANAGER (PLUS-X) . $25.00

For PC/XT/AT and Compatible.
5.25" & 3.5" floppies. Add $3.00 if outside U.S. and Canada. Az. orders add 5.5% state tax.

CALL SIGN REQUIRED W/ ORDER.
*Requires computer ready transceiver.

CIRCLE 262 ON READER SERVICE CARD

minute—how do you know that the frequency you are measuring is right on in the first place?

Find yourself a commercial FM radio station tower. FM broadcast stations are constantly monitored by the FCC and the FM station chief engineer for being on frequency within just a cycle or two. Get within a ballpark length of a big FM radio station antenna, and your counter now jumps to life. Many counters require a tiny jeweler's screwdriver to make the calibration adjustment, and you must remove the screwdriver each time you take a reading. First, take readings at the fast gate time to get close, then go to the long gate time for final adjustments. When everything reads out right on the center frequency, you know your counter is on the money. Every town has its own FM broadcast station, so use them to your counter's calibration advantage!

Resolve your Frequency

For sniffing out unknown frequencies, run your counter in the fast gate time. Use slow gate times only for actively calibrating equipment, or checking a set for on-frequency operation. NEVER hook the output of the transceiver directly to the input of the counter—it will surely blow the input IC or transistorized preamp stages in high sensitivity models.

Every ham should own their own counter. I use my counter on almost a daily basis. 73

You may contact Gordon West WB6NOA at 2414 College Drive, Costa Mesa CA 92626.

In 1937, Stan Burghardt (WØIT), because of his intense interest in amateur radio, began selling and servicing amateur radio equipment in conjunction with his radio parts business. We stand proud of this long-lasting tradition of ***Honest Dealing, Quality Products and Dependable "S-E-R-V-I-C-E"!***

Above all, we fully intend to carry on this proud tradition with even more new product lines plus the same *"fair"* treatment you've come to rely on. Our reconditioned equipment is of the finest quality with ***30, 60*** and even ***90-day*** parts and labor warranties on selected pieces. ***And always remember:***

The Kenwood TS-850S

Kenwood USA
P.O. Box 22745
2201 E. Dominguez Street
Long Beach CA 90801-5745
Telephone: (213) 639-9000
Price Class: TS-850S, $1700; DSP-100, $630

A versatile HF transceiver with a digital difference.

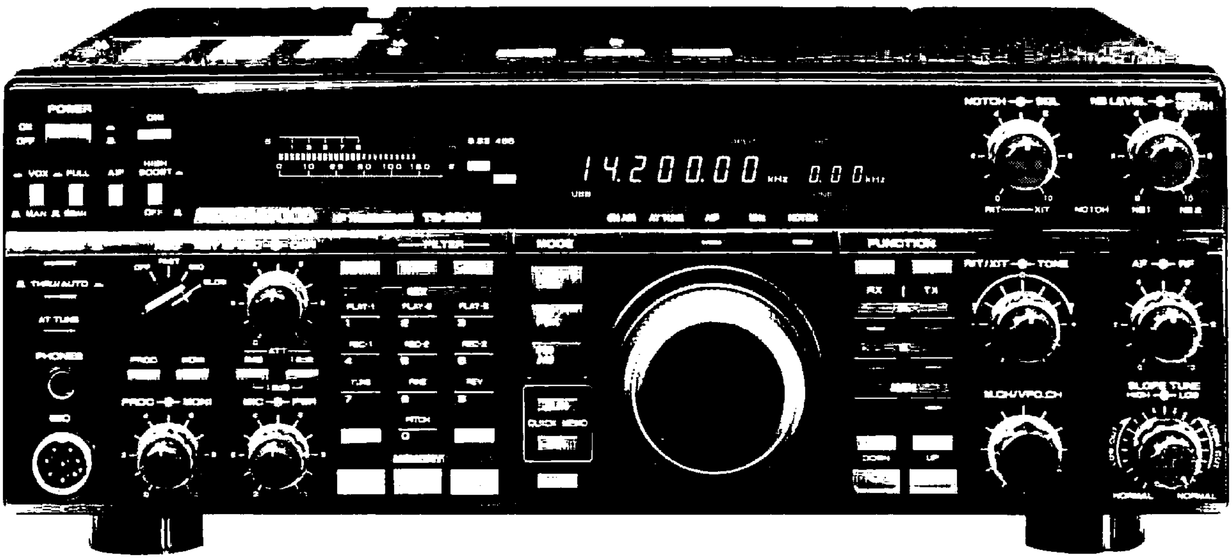

Photo. The Kenwood TS-850S HF transceiver.

Unless you've been holed up somewhere, you must have heard of the TS-850S by now. You might even have worked a few on the air. Let's take a look at the amazing attributes of the TS-850S "Digital Machine."

The Manual

The TS-850 manual is fairly well done. It's long enough (74 pages), but in parts it's a bit tedious (translation warp?), like when you find yourself reading a section two or three times to get the exact meaning. But then, I had intended to read it anyway, eventually. (The DSP-100 instruction manual, on the other hand, is a short six pages.)

The "Specifications" and "Installation" chapters are short and concise. They are followed by "Operations." This is the section that relates the functions and controls, and explains how to actually operate the new equipment. To somebody upgrading from an early '70s rig, like an SB-100, up into the '90s, the next 50 pages is where "the rubber meets the road." I prefer to be sitting in front of the unit, power applied, as I work my way through the text and actually perform each detail and step as I go along. The results of a function or operation are instantaneous, and the act of involving more than just the eye/brain makes it easier to relate and remember.

The sections are divided functionally, with page numbers showing where each block of detailed description begins.

The "Circuit Description" section is actually 10 pages of schematics without text. I'd like to see an in-depth step-by-step description of the inner workings and refinements of a unit's various electronic subsections. I know it is pretty rare these days, but it's invaluable when included.

Features

Let's take a look at some of the unique or noteworthy functions, starting at the upper left of the front panel and proceeding clockwise (see the photo above).

AIP: The Advanced Intercept Point, when actuated, bypasses the first RF amplifier stage with a unity gain stage and, as the manual states, reduces interference from strong nearby signals. Input sensitivity drops about 10 dB and the intercept point refers to the third order input intercept.

HIGH BOOST: This is a tone-shaping switch that increases the high frequency roll-off of the mike amp circuit. I made a check on 75m one night with WB8ELK, who lives about four miles down the road and who knows what my voice sounds like. He reported that it sounded most natural with the boost ON. I've kept it on ever since.

DISPLAY: The display is well laid out and intuitive. There's an incredible amount of information compacted into the seven-square-inch area. I still haven't totally accepted the bar graph meter, but that's the opinion of someone who has five analog meters on his home-brew linear amplifier. The bar graph is an S-meter in receive, and indicates power and a choice of SWR, ALC or compression in transmit. It has 30 dis-

crete segments and will hold the peak reading for about a second (if you select the peak-hold function in the soft menu).

NOISE BLANKER: There are two. NB1 is designed for short duration noise, such as ignition noise; NB2 is for longer duration noise, such as the "woodpecker" over-the-horizon radar.

SLOPE TUNE: You may know how it works, but maybe not how well. In a pile-up you've got to have the optional 1.8 kHz SSB filter, but for the average QSO where suddenly a nearby (1.5 kHz or so) signal pops up, the high cut slope tune really works nicely. High frequency QRM can be totally eliminated without changing the audio quality of the desired signal whatsoever. I'd find myself swinging the cut knob in and out again to see if the adjacent station was still transmitting. He was. The low cut works equally as well (in USB). Totally effective!

M.CH/VFO.CH: This dual-function knob is linked to a 24-position optical shaft encoder. In memory mode it quickly scrolls through the 100 channels of memory. In VFO mode it will step the frequency through in user-programmed steps of 10, 5 or 1 kHz, from the top to the bottom of the band, in less than two quick turns of the knob.

QUICK MEMO: There are five FIFO-type scroll memories which store all set-up and frequency information (receive/transmit frequency, modes, filters, meter selections, antenna tuner setting, etc.) in a stacked fashion. As new frequencies are stored, the oldest (or first) is shoved off the register. This is extremely useful for a scratch pad of activity on a band, and instant recall to any of the five "memos" takes just one keystroke.

FUNCTION: The selection of RX/TX split frequencies for a particular VFO or memory is extremely clear and intuitive. Each push-button is LED-backlit, so you can see the status at a glance.

KEYPAD: This 12-button keypad functions as a direct frequency entry and doubles as a control for the following additional functions: record and playback of the three tracks of the optional DRU-2 digital voice recorder; FINE tuning at a rate of 1 kHz per revolution (it feels almost like an analog VFO); TUNE, which puts out half-power in XMIT and enables zero-beat without carrier in CW; REVerse, which toggles to the opposite sideband in CW receive and XMIT; and PITCH, which selects the tone of the received CW signal.

Digital Signal Processing

The function of any DSP system can be described as follows: The signal is acquired and converted to digital form via an ADC (analog to digital converter), the digitized data is processed by simple fast algorithms, and the results are converted back into a usable form via a DAC (digital-to-analog converter) or stored in memory. The foundation of DSP is Shannon's sampling theorem (you may have heard it before, but here it comes again) which states that a signal must be sampled at a rate that is at least twice as high as the highest frequency in the signal's spectrum.

DSPs are characterized by a small address space, a small specialized instruction set, limited addressing modes, separate data and program paths and, most importantly, a single cycle execution of instructions. General purpose microprocessors are microcoded, meaning that each machine instruction (neunomic) executes an internal "micro" program within the CPU. These neumonics are hardwire-decoded within the processor. This conserves silicon (less costly) and yields a functionally generic microcircuit whose process is dependent upon the microcode. This is what put Intel into the "Fortune 500,"...that little 4004 started it all. Unfortunately, microcoding increases instruction execution time, using multiple internal clock cycles for each instruction. On an 8051, for instance, an External Data Memory bus cycle consists of 12 clock cycles, or T-states, just to fetch data located in off-chip memory. An instruction execution can consume anywhere from 500 ns to hundreds of microseconds. A DSP executes instructions, including the all-important multiply and shift instruction in a single 25 ns to 200 ns operation.

Microprocessors have a single memory used for both data and instructions. They are referred to as Von Neuman Machines. DSPs are Harvard Machines, i.e., they have separate data and program memory (and busses). This feature allows them to simultaneously fetch an instruction and data operand and perform the specified operation at the same time. The Motorola 56000 has two distinct data memories and can operate on both of them in a single cycle. Data memory to a DSP is equivalent to a large bank of general purpose data registers like those found in a standard processor, and can be used in similar ways. DSPs have been optimized to execute a sum-of-products function of the form $A=B\bullet C+D\bullet E+F\bullet G+....+X\bullet Y$. Notice that this is the basic element of a digital filter!

A microprocessor has a problem executing binary, fixed-point arithmetic. When a value overflows a register, it "wraps" around, going from positive to negative or vice-versa. The maximum value can be anticipated, or the calculation can constantly be sampled for overflow, requiring the register to be reset if necessary. DSPs on the other hand have a built-in facility to curb this problem. There is a barrel shifter (a large shift register with the output of the last stage fed back to the input of the first stage) built into the ALU that allows a binary number to be shifted any number of bits in a single cycle. Thus, you can multiply or divide by any power of two in the same cycle. Using multiply and accumulate instructions, the accumulator can be shifted in the same instruction before the result is stored. This allows the binary point of the arithmetic to be moved with little effort. Crunch, crunch crunch!

The DSP Interface

The introduction of the DSP-100 represents one of the first applications of this new technology in a commercial communications receiver, but the effort falls a bit short. The instruction manual states: "Since the processing is done at an IF level, it results in a more copyable signal. Not only are you able to tailor the audio frequency response, but because the signal has been digitally processed it also appears to be cleaner or more crisp." I searched to find the situation where this was so, because this new technology is truly exciting and veritably budding with new and tremendous potential. Under a myriad of different operating conditions and bands and times of day, the unit did not perform any better than the excellent selectivity and interference rejection capabilities of the IF slope tuning of the basic TS-850S.

One of the problems inherent to the design is that the filter switches have only four discrete positions, and the span of the selection is much too limited. The LPF (low pass filter) switch selects 100, 200, 300, and 400 Hz as the roll-off frequency, and that's it. Likewise, the HPF selects 2600 to 3100 Hz in four steps. Technically, it wouldn't be unfeasible for the upper and lower skirts to extend far enough to overlap, and thus comprise an agile digital notch with very precise width and form factors. In the transmit mode I simply had to take Kenwood's word for the purported improvement in suppression of the unwanted sideband. I performed numerous air checks with and without the DSP and most hams could detect no difference.

In CW TX mode, the rise and fall times are adjustable in steps of 2 ms from 2 to 8 ms, presumably to give a softer sounding signal. The difference was evident on the SM220 Monitorscope. The rise time was precisely as it should be, with no overshoot.

Impressions

Twelve volt operation is really a plus! The ability to stay prepared to assist in an emergency is as important a function of our hobby as any other single facet. We should be thinking more about deep-discharge batteries, windchargers and solar panels, and kick the power grid habit.

The power-on-function-selection is one of my favorite features. With one finger, press and hold the USB/LSB key while pushing on the power button. You are into a mode that allows for the customizing of 34 different functions. From sub-tones (burst or continuous) to (bug or iambic keyer) to (RIT range of ± 1.27 or 2.54 kHz) to (FSK shift of 170 to 850 Hz) to (10 Hz display resolution ON/OFF), etc. The values are set once and held in non-volatile RAM. Remove power and power up again and the values will be in effect.

Shortwave listening (SWLing) is very easy with the TS-850S. One of the programmable functions just described allows for the selection of the step rate (10 kHz/5 kHz/1 kHz) of the 24-position VFO channel knob. If you set the width to 5 kHz, the rig will step exactly to the assigned channels of the SW broadcast

bands, thus effectively channelizing precisely. It couldn't be easier. With a tone control knob and plenty of excellent audio, SWLing became one of my favorite program sources when working on projects in the shack or pounding the Mac. I had a surprising renewal of interest in BBC, DeucheWelle, Radio Moscow, etc., and with 100 memories, there's plenty of room to store some prime frequencies.

I really have to stretch a bit to think of anything very negative to say about the TS-850S. I didn't like the RIT span limitations and the fact that it wouldn't reset when returned to later. The potentiometer retains rotation memory (with no center detent). Also, there was not a direct line-level connection from the digital voice recorder to the audio line, except by acoustic coupling (mike up to the speaker).

The automatic antenna tuner is fast and accurate, with very little overshoot or hunting, and the full CW break-in was extremely quick. It was a new experience for me to have it be that quick, and a bit distracting to hear the band condition between dots. When someone would start transmitting nearby while I was sending, I had to knuckle down and really concentratel

My overall feeling about the TS850S was very, very positive.

There's a function on my decade-old TS-180 which should be in this receiver: frequency difference, between VFO and selected memory. This makes it possible to search for a clear frequency when trying to QSY, and then pop back on frequency and report "up 4.6 kHz," since it is displayed in readout.

The DSP-100 interface heralds the exciting future of digital signal processing into amateur radio and we should be glad to see its arrival. It will be exciting to see what the next generation will be like. I bet it won't be long, 'cause we "ain't seen nuttin yet." 73

TS-850S Specifications

GENERAL	Transmitter frequency range	160, 80, 40, 30, 20, 17, 15, 12, 10 meters
	Receiver frequency range	100 kHz–30 MHz
	Mode	A3J [J3E] (USB LSB), A1 [A1A] (CW), F1 [F1D] (FSK), F3 [F3E] (FM), A3 [A3E] (AM)
	Antenna impedance	50Ω
	Power requirement	13.8 VDC ±15%
	Power consumption	Max transmit 20.5 A; receive (no signal) 2 A
	Dimensions	13"W x 4.7" H x 13" D
	Weight	11 kg (24.25 lbs.) approx.
TRANSMITTER	Final power output	SSB/CW/FM/FSK—100W, AM—40W
	Modulation	SSB—Balanced modulation FM—Reactance modulation AM—Low level modulation
	FM maximum frequency deviation	±5 kHz
	Carrier suppression	Less than −40 dB (Modulation frequency 1.5 kHz)
	Spurious response	Less than −60 dB (CW)
	Unwanted sideband suppression	Better than 40 dB (Modulation frequency 1.5 kHz)
	Microphone impedance	600Ω
	Frequency response	400 ~ 2600 Hz (−6 dB) (SSB)
RECEIVER	Circuitry	Triple conversion system
	Intermediate frequency	1st IF—73.05 MHz, 2nd IF—8.83 MHz, 3rd IF—455 kHz
	Image Ratio	780 dB
	IF Rejection	780 dB
	Selectivity	SSB/CW/FSK—2.4 kHz (−6 dB), 3.8 kHz (−60 dB) AM—8 kHz (−6 dB), 15 kHz (−60 dB) FM—12 kHz (− 6 dB), 24 kHz (minus 60 dB)
	RIT/XIT variable range	±1.2 kHz (10 Hz step), ±2.4 kHz (20 Hz step)
	Notch filter attenuation	More than 40 dB, (audio frequency 1.5 kHz)
	Audio output power	1.5W (8Ω at 10% distortion)

DSP-100 Specifications

Mode	J3E (LSB, USB), A1A (CW), A3E (AM), F1A (FSK)
Output frequency	455 kHz
Input frequency	36.891 MHz
Modulation	SSB—Balanced modulation AM—Low level modulation
Dimensions (W x H x D)	270 x 49 x 286mm (10-5/8" x 2-3/16" x 11-1/16")
Weight	3kg (6.6 lbs.)

Half-Wave Gain Antenna

For 450 MHz Handie-Talkies

by Phil Salas AD5X

Over the past decade, the 450 MHz band has become as popular as the 2 meter band. Many 450 MHz repeaters have even more features than 2 meter repeaters, including multiband, cross-band repeater operation. Like 2 meters, handie-talkies are also very popular at 450 MHz. Unfortunately, there's not much to be said for the antennas available on these handie-talkies. This article describes a better antenna solution for your 450 MHz handie-talkie.

450 MHz Antennas

450 MHz antennas are generally a quarter wavelength long (about 6-1/2 inches), but don't perform like quarter-wave antennas. I made some measurements using my handie-talkie antenna mounted on a mag-mount base on my car, and compared them to measurements with the antenna mounted directly on the handie-talkie. My test equipment consisted of an ICOM R-7000 receiver, a Smith Engineering Spectrum Probe, and an oscilloscope to display the spectrum. My measurements were made from a range of 100 feet.

The antenna used on the R-7000 was a half-wave sleeve antenna on the end of a 20-foot piece of RG-8M so that I could move it around and verify that I was not getting signal enhancement or cancellation due to reflections. My tests showed a clear and repeatable 2–3 dB advantage of the handie-talkie antenna when mounted on the car versus mounted on the handie-talkie. I suspected that this was due to the quarter-wave antenna requiring a decent ground plane for proper operation. When mounted on the handie-talkie, the ground plane consists of the handie-talkie electronics and case capacitively coupled to the hand of the user.

If this is the case, then a half-wave antenna might be the solution. A half-wave antenna supplies its own image, and therefore doesn't need a good ground plane. And a half-wavelength at 445 MHz is only 13 inches long—certainly a reasonable handie-talkie antenna length. Unfortunately, an end-fed half-wavelength antenna exhibits a very high feedpoint impedance; fortunately, matching to this impedance is not necessarily difficult.

Half-Wave, End-Fed Antenna

Since the half-wave, end-fed antenna exhibits a high impedance, it can be matched with a parallel tuned circuit, the input to this tuned circuit being tapped at such point to give a 50 ohm impedance. This is shown schematically in Figure 1.

The first part of the job involves preparing

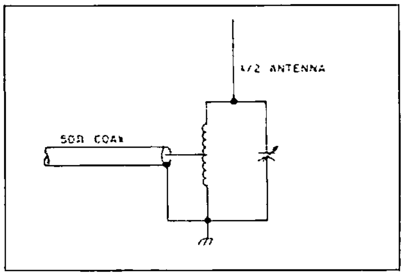

Figure 1. A half-wave gain antenna that takes only an hour to build.

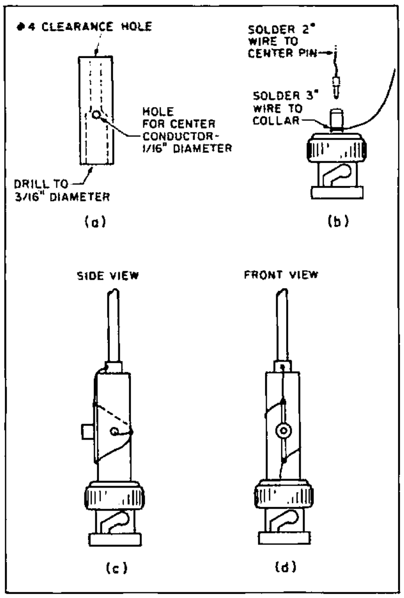

Figure 2. (a) Drilling the holes and (b) soldering the wire. (c) A side and (d) front view of the half-wave gain antenna.

the coil form. The plastic spacer has a small clearance hole drilled through it. Refer to Figure 2. Use a 3/16-inch diameter drill to drill out this clearance hole halfway through the length of the spacer. Now drill a 1/16-inch diameter hole into one side of the spacer as shown in the figure.

Referring to Figure 2(b), solder a three-inch wire to the side of the collar of the BNC plug as shown. Solder a two-inch wire to the center pin. Insert the center pin into the BNC plug. Drop a piece of sleeving over the center pin wire to prevent shorts, and add a drop of quick-setting glue over the end of the insulated wire to keep the center conductor in place.

Add a drop of quick setting glue to the screw threads on the 13-inch telescoping antenna and screw the threads into the spacer. Now feed the free end of the wire soldered to the center pin of the BNC plug into the spacer and out the hole in the side of the spacer. Press the spacer down over the BNC plug's collar such that the side hole is one-forth of the way around the connector from the wire soldered to the connector body. Now we can create the parallel L/C network.

Wrap the wire soldered to the connector body once around the spacer and solder the end to the base of the telescoping whip antenna. Refer to Figures 2(c) and (d), soldering the variable capacitor across the single turn as shown. Finally, bend the center conductor wire extending from the spacer side hole around and solder this wire to the center of the coil exactly opposite the capacitor. You are now ready to adjust the antenna.

Antenna Tune Up

To tune up the antenna, fully extend it, place it directly on the output connector of an SWR meter, and hold it vertically. Since the initial SWR is likely to be quite high, you should operate your transmitter at low power to protect the final output transistor.

Now, key your transmitter and set your forward reference. Switch to reflected power and adjust the capacitor for a minimum reading. It should be easy to see the dip. Reset your forward reference and measure your SWR. It will undoubtedly still be high. Unsolder the center conductor wire from its position on the coil and resolder it repositioned a little closer to the ground

Parts List

crimp-on BNC male plug	50 ohm	Mouser ME174-93701N
spacer	plastic or nylon 5/8"L x 1/4" dia.	Mouser 561-K4.625
capacitor	3.5–20 pf miniature variable	Mouser 24AA072
whip antenna	13" telescoping	Radio Shack 270-1407

I obtained the first three items from Mouser Electronics (800-346-6873). You can get these items from many different suppliers. The variable capacitor needs to cover the 6–10 pF range.

end of the coil. Repeat the capacitor dip adjustment and SWR reading. You may have to move the center conductor wire a few more times, but it will be very easy to achieve an SWR of close to 1:1.

When you have achieved a good SWR, carefully coat the entire coil with hot glue. Do not cover up the variable capacitor yet, though. Also coat the coil/connector and coil/antenna interfaces with hot glue. When the glue cools, re-check the SWR and re-adjust the capacitor if necessary. Now go ahead and cover the variable capacitor with hot glue. Your half-wave antenna is finished!

Antenna Comparisons

I re-ran my antenna tests comparing the half-wave antenna mounted on the handie-talkie with the original quarter-wave rubber duckie also mounted on the handie-talkie. Again, the measurements were made at 100 feet using the ICOM R-7000 receiver, Spectrum Probe, and oscilloscope. I measured a solid 6 db improvement of the half-wave antenna over the standard rubber duckie. This is pretty impressive. It is the equivalent of raising your transmit power by a factor of four!

I have described an inexpensive half-wave gain antenna for your 450 MHz handie-talkie. The total time to build this antenna after you have all the parts is only about an hour. Not bad for a 6 dB gain advantage! 73

Model 3500 Frequency Counter

Speed, accuracy, and ease in a shirt-pocket unit.

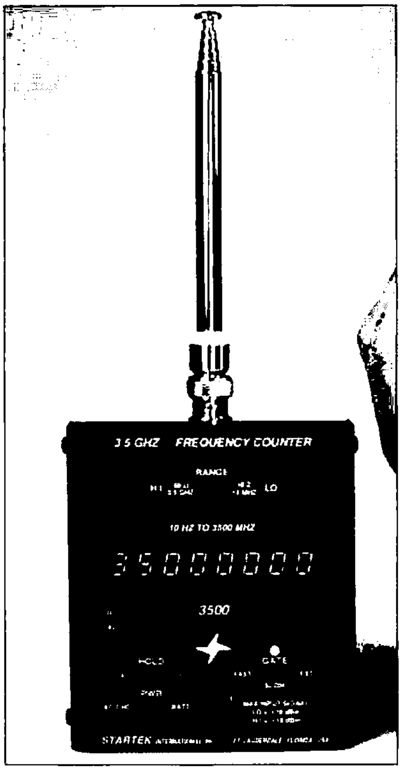
In the old days, you could tell a lot about a ham radio operator just by looking at his workbench. A fast glance over a ham's tools and test equipment can quickly determine his level of expertise and commitment. What do you see? A cereal box DC voltmeter and a CB SWR bridge? (Hmmm. Not too serious.) A decent meter, an audio signal generator, and a few home-brew gadgets? (Getting closer.) Eight or 10 big mysterious boxes, an oscilloscope or two on a cart, and a big RF frequency counter? (Aha! A real hard-core.) A digital voltmeter and a shirt-pocket frequency counter . . .

A shirt-pocket *what*? A shirt-pocket frequency counter. Those of us who grew up with 80-pound boat anchors sporting dancing Nixie tubes and prescalers may find it hard to believe, but the Startek International Model 3500 does indeed fit in a standard shirt pocket (as does the whole Startek line). Not only does the 3500 take up less space than your old buddy, but it's faster, easier to use, and more accurate. How do they do it?

Micro Package—Big Features

The answer, of course, is modern technology. The Model 3500 uses a combination of LSI and MMIC chip technology to produce a device that is extremely sensitive over a wide frequency range. Like most counters, the unit has selectable ranges, in this case 10 Hz to 12 MHz and 10 MHz to 3.5 GHz. Unlike older models, the 3500 selects a high impedance mode for the low range, and a 50 ohm impedance for the high range. This eliminates the problem that often occurs when trying to measure the frequency of a low-level oscillator in a radio. A standard counter will load down the circuit, killing the oscillations. Even worse, in some situations the counter will load down the circuit just enough to vary the actual frequency of the oscillator. This produces a respectable-looking but entirely incorrect reading. The high impedance mode fixes both of these problems.

The 3500 and the entire Startek line all use eight-digit LED displays. The debate over LEDs versus LCDs will probably go on forever, but I prefer LEDs. The majority of radio service work is done in dimly lit areas—basements, attics, hilltop radio shacks—where the LED outperforms the LCD hands down. In addition, in the few instances where the unit needs to be used outdoors, the display is easily shielded.



The Startek Model 3500 frequency counter.

The display resolution changes along with the GATE switch. Using the EXT gate position, you can resolve frequencies down to 0.1 Hz on the low range and 10 Hz on the high range. One nice feature of the 3500 is the ability to select three different gate times (see the table for gate times versus resolution). A DISPLAY HOLD feature locks the active readout for later reference or recording. Maximum input levels are stated to be +10 dBw and +15 dBm for the low and high ranges, respectively. These values figure out to 10 watts and 30 mW, respectively. This means that the 3500 has a high degree of overload protection, but it doesn't mean it's bulletproof. It will still die if you key your mobile rig directly into it. However, it's less likely to become "deaf" from people waving handhelds next to its antenna.

Sensitivity

Sensitivity figures for the 3500 are shown in the table. The review unit exceeded these values across the entire range of frequencies. This is impressive enough from a technical standpoint, but what it means in terms of actual use is even more exciting.

The days of counter preamps are long gone. Not only are the Startek counters sensitive enough for any general troubleshooting, they also work well for remotely monitoring transmissions. The 3500 was able to reliably count the frequency of a 2 meter, 5 watt handheld, using a rubber ducky antenna, at 150 feet. A 50 mW signal operating into a one-foot whip could be read at 20 feet. This characteristic makes the counter a very versatile tool. Public service monitoring, surveillance work, intermod and interference problems, transmitter hunting—several applications immediately become apparent. (If you've always wondered what the frequency was at the drive-in window of Bob's Taco Stand, this is the instrument for you.)

Unlike most RF counters, this unit works well down to 10 Hz. This makes it useful for a variety of audio functions as well—counting CTCSS (PL) tones, checking DTMF microphone frequencies, and verifying two-tone encoder tones.

Features

The Model 3500 comes with the basic supplies needed for day-to-day use: a built-in NiCd supply and a plug-in wall charger. (A telescoping antenna to fit the BNC input jack is available as an option.) Optional accessories include a carrying case, different probes for "in circuit" testing, and a rubber duck style antenna. The NiCd pack will power the unit for four hours before recharging.

The idea of servicing a service instrument is never foremost on one's mind when buying one, but the Startek counter carries a one-year parts and labor warranty. Due to its size, the unit will spend most of its time in a relatively safe corner of a toolbox or coat pocket, but

Model 3500 Specifications

The Heli-Hat Antenna

An 18-inch wonder for 10–17 meters.

by J. Frank Brumbaugh KB4ZGC

What is compact, portable, and efficient? Covers 17 through 10 meters? Is omnidirectional, with low angle radiation? Reduces QRM, QRN, and harmonics? Has one-knob tuning for low SWR?

More and more hams find themselves living in subdivisions, apartments, and condominiums where deed and building restrictions make normal antenna installations impossible. Hams in mobile home parks, and those ranging the country in motor homes, have few options for useful antennas other than loaded vertical whips—mobile antennas. These are useful for the higher HF bands, but commercial versions are very expensive. What they need is an antenna with the above features.

Although I now have a 40 meter dipole for HF use, there have been many times during my 40-plus years as a rag-chewer when I lived in locations where even a whip antenna on a balcony was frowned upon. I experimented with many different antenna configurations. Some worked quite well. Others were duds. The more-or-less standard dipoles and quarter-wave wires, even bent to fit the available indoor space, generally gave satisfactory results when properly tuned. However, even small gauge wires strung around a small apartment were sometimes noticed and questioned by landlords, requiring elaborate explanations—lies—which seldom were believed. What was needed was a compact, effective HF antenna that could be easily hidden in a closet or attic when "official" visitors were expected.

Such an antenna should be of a size that could easily be transported in an automobile and rapidly set up in a motel room, or even put on top of the car for fixed mobile operation on Field Day. The Heli-Hat Antenna was my solution to this problem. It has all the features I opened this article with!

Originally designed before WARC to operate on 10 and 15 meters, it has been used since then on 17 and 12 meters, and results have been most satisfactory. This antenna may well be of interest to other hams with similar antenna problems, or as a "quick and dirty" Field Day antenna.

Table. Taps vs. Frequency

Band, Meters	Tap	SWR
17	7	1.1:1
15	7	1.2:1
12	6	1.2:1
10	6	1.1:1

Note: Tap points measured from bottom of helix. The 10-meter tap is for 28.4 MHz and may vary at higher frequencies. Taps for other bands are for centers of bands.

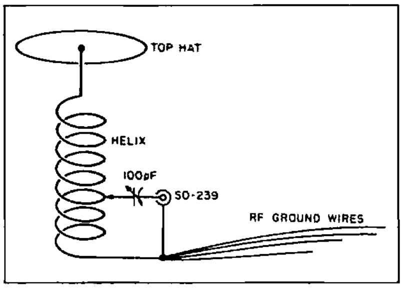

Figure 1. Heli-Hat antenna schematic diagram.

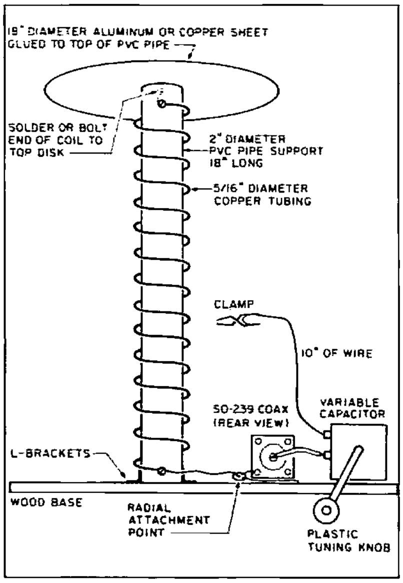

Figure 2. Construction details of the Heli-Hat.

Heli-Hat Antenna

The antenna, illustrated schematically in Figure 1, covers the 17, 15, 12 and 10 meter bands. It includes one-knob tuning so SWR can be reduced well below 1.5:1—usually 1.1:1 or 1.2:1, making it compatible with modern solid-state transceivers. It is compact, fitting into a space approximately 18 inches high and 18 inches in diameter. With the top hat removed it takes up about as much space as two loaves of bread staked end-to-end.

Basically, the antenna is a tuned, top-loaded helix. A portion of the base of the helix, tuned by a 100 pF variable capacitor, resonates at the operating frequency and simultaneously presents a nonreactive 50 ohm load to the transmitter or transceiver. The upper portion of the helix is tuned by the effective capacitance of the top hat at the operating frequency. The entire antenna structure radiates.

This is a high-Q antenna, so it exhibits a relatively narrow bandwidth. This requires slight adjustment of the tuning if a large frequency excursion is made, especially on the 15 and 10 meter bands. A major advantage of such a high-Q antenna is that it rejects any harmonic energy which may be present on transmit, and on receive it reduces the level of signals near the operating frequency in a manner similar to the way a peaked filter functions. Not only will this antenna reduce QRM, it also reduces QRN to a great extent because of its narrow bandwidth.

The base of the helix must be grounded for RF. In most indoor installations this can be best accomplished by attaching open-ended quarter-wavelength wires to the ground connection, a solder lug on one of the screws holding the RF connector to the antenna base. Ground wires can be stretched out while operating, and rolled up and stowed with the antenna when not in use.

For operation on all four HF bands, the four wires should be cut to 13 feet 7 inches; 11 feet 7 inches; 9 feet 10 inches; and 8 feet 6 inches, respectively, for the 17, 15, 12 and 10 meter bands. Four separate insulated wires can be used; or two pairs of 2-conductor speaker wire, or even a length of 4-wire telephone cable such as that used indoors. Each wire should be cut to the length specified, and one end of all wires connected to the ground lug on the SO-239 RF connector on the antenna.

Continued on page 35

Continued from page 32

WARNING: *When transmitting, the entire antenna structure as well as the open ends of the ground wires will exhibit high RF voltages which can produce burns if touched. Be certain your installation is protected from being touched by children or pets.*

Finding The Parts

New copper tubing is rather expensive, but the length required should not break any ham's budget. Scrap tubing, copper or aluminum, is often available for little or nothing at businesses involved in manufacturing and installation of refrigeration and heating/air-conditioning systems. The tubing I used was obtained from an air-conditioning installer for $2.00. It is also often possible to locate a sufficient length of cable TV hard-line—spool ends containing as much as 80 or 90 feet are usually discarded—and if you explain your intended use to one of the technicians, you probably can get as much as you need free of charge. Although copper tubing is best, aluminum can be used in constructing the Heli-Hat antenna.

The 100 pF variable capacitor I used has 0.03-inch plate spacing, which is OK for up to 100 watts. For 500 watts a plate spacing of 0.05 inches is recommended, and up to 0.1-inch spacing for maximum legal power. My capacitor came from the lowest depths of my junk box. It is odd, with trapezoidal-shaped stator plates, removed long ago from some esoteric military "boat anchor."

Fair Radio Sales, P.O. Box 1105, Lima OH 45802, has a broad selection of surplus variable capacitors at prices ranging from $1.25 to several dollars. (New variable capacitors bear prices that equal a day's wages or more! Surplus is better.) However, before spending scarce dollars, check with local hams and the flea markets at hamfests for a suitable capacitor. Also, Radiokit at P.O. Box 973, Pelham NH 03076, tel: (603) 635-2235, carries a number of suitable capacitors. Two good candidates are their model number 284130 for higher power, and number 23100MK for under 100 watts.

Aluminum sheets two feet square are often available in hardware stores as "Reynolds® Do-it Yourself" supplies. Hardware and building supply stores also usually have two-foot-wide aluminum flashing for sale. Either will be suitable for the top hat, which is 18 inches in diameter.

Scrap PVC pipe and wood for the antenna base may often be found in scrap piles behind hardware and building supply stores, although the short length of pipe needed should cost less than a dollar purchased new. It can be either larger or smaller in diameter than that specified herein. Its only function is to provide stability to the tubing helix.

Construction

The helix consists of 15 turns of 5/16-inch copper tubing about 4-3/4 inches in diameter, with the turns evenly spaced over a length of 14 inches. The total length of tubing is about 19 feet. The helix was formed by winding around a cardboard tube about 3-1/2 inches in diameter, springing to its final diameter when removed from the cardboard. Ends of the tubing are flattened and drilled to accept long machine screws, then slipped over the PVC pipe and bolted through it. The pipe is about 18 inches long and about 2 inches in diameter.

NOTE: The dimensions given are those of my antenna. You may make any changes *within reason* in any of these dimensions. Tubing of larger or smaller diameter can be used; overall tubing length can be greater or a bit less. Helix diameter can be reduced and length extended. The result of such minor changes may change the position of the tap point for one or more bands but otherwise should make no important difference.

The top hat is an 18-inch diameter disc of aluminum sheet with an area of over 254 square inches. It need not be round as long as the area is close to 254 square inches. The effective capacitance of the top hat is important to both the frequency range covered and to the Q of the antenna.

The top hat can be attached to the top of the PVC pipe with epoxy or hot glue. A ground lug attached to the underside of the tip hat near the PVC pipe is used to connect a short wire jumper between it and the top of the helix.

The lower end of the PVC pipe can be mounted on a short piece of wood, plywood or plastic, using brackets and machine screws. It may also be attached with epoxy or hot glue, although this will not produce a very strong joint.

The tuning capacitor must have both rotor and stator plates insulated from ground because it is in series with the RF from the transmitter or transceiver and the tap on the helix. Either a length of insulating shaft or a large plastic knob must be used on the tuning capacitor shaft, which will be "hot" with RF. Mount the capacitor on the base near the PVC pipe.

An SO-239 RF connector can be connected to a bracket attached to the antenna base near the tuning capacitor. Mount a ground lug under two of the screws holding the connector on the bracket. Connect a wire jumper from one ground lug to the base of the helix. The other ground lug is the connection for the four RF ground wires mentioned earlier.

Connect a wire jumper between the center terminal of the SO-239 to either the rotor or stator of the tuning capacitor. Solder both connections.

Strip some insulation from both ends of a flexible stranded wire of AWG #16 or larger and about 10 or 12 inches long. Connect one end to the unused terminal on the tuning capacitor, and solder.

Connect a spring clip to the other end of this wire. An alligator or crocodile clip may be used, but a small spring clip of the type used on automobile jumper cables and battery chargers works best. This clip is used to establish the tap point of the helix for each band, and must make a solid, low resistance connection.

Operation

Attach the ground wires to the unused solder lug on the SO-239 connector and stretch them out more-or-less in a straight line. Using a coaxial jumper, connect the RF output of your transceiver or transmitter to the SO-239 on the antenna, providing your rig includes a means for monitoring SWR. If it does not, an SWR meter must be connected between the transmitter or transceiver and the antenna.

If you've followed the measurements given in this article closely, position the tap on the helix as indicated in the table. If your antenna differs in dimensions, the proper tap point must be determined experimentally.

Apply 10 to 25 watts to the antenna and adjust the tuning capacitor for the lowest SWR. In some installations it may be necessary to move the tap point on the helix one-half to one turn higher or lower to achieve an SWR of 1.1 or 1.2, although if the SWR is at least below 1.5:1, modern solid-state rigs will operate satisfactorily.

Monitor the SWR when you change frequencies or bands, and change the tap position and adjust the tuning capacitor as necessary to maintain low SWR.

Conclusion

The Heli-Hat antenna is omnidirectional and radiates much of the RF at the low vertical angles best for DX. It is a high-Q antenna with a narrow bandwidth around the operating frequency, resulting in the reduction of QRM and QRN on receive, and greatly reducing the level of any harmonic energy that might be present in the output of the transmitter or transceiver. It covers all four ham bands from 17 through 10 meters and is easily tuned for a very low SWR. The antenna is easily set up indoors or out, and is easy to conceal when not in use. It can, in many cases, be constructed wholly from scrap.

Although the Heli-Hat antenna was designed to cover only the four highest HF bands, theory suggests it also could be tuned on 6 meters, and possibly 2 meters as well, by tapping the helix closer to ground. Not having equipment for these bands, I was unable to check for operation on these frequencies.

Too, if the helix is made from a longer length of tubing, and perhaps has a larger top hat, it should be possible to extend the lower frequency limit to include the 20 meter band without making the antenna much larger.

Although the Heli-Hat antenna is not intended to compete with a 6-element monoband beam on a 100-foot tower, it will give a good account of itself on the four ham bands for which it was designed, especially on crowded bands where its high Q is a distinct advantage.

This antenna also can be a starting point for experimentally minded hams who may be interested in modifying it to cover other frequency ranges.

73 Review

by Bill Clarke WA4BLC

The Solarcon A-99 Antenna

A very economical vertical for 10–17 meters!

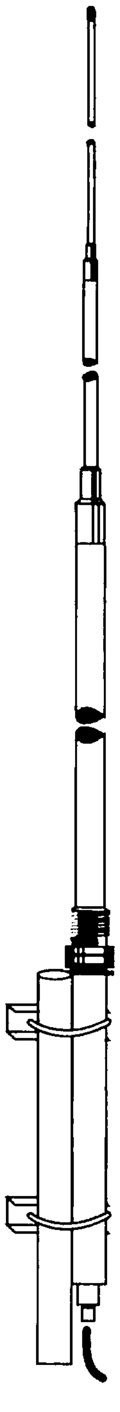

Figure. Diagram of the Solarcon A-99 antenna.

A while back I was reading one of the ham magazines and saw an advertisement that really piqued my interest. It said, "World's top performing fiberglass omnidirectional base station antenna," then went on to say that it operates 12–10 meters. This was too much to let pass by, so I sent for one.

The box arrived via UPS and inside were three pieces of fiberglass-covered tubular antenna. I also found an instruction sheet and a few other papers. I quickly went about getting the antenna into the air for testing.

Assembly

This antenna is easy to assemble. The three pieces screw into each other and the bottom of the antenna has a metal sleeve which is then attached to a tower, post, or mast with U-bolts. Coax is attached to a weather-protected connector in the center of the antenna's base.

For the first few days of evaluation, I bolted the antenna to an eight-foot-long, two-inch-diameter wood rod and tied it to the side of my tractor, which was then parked about 75 feet from the house.

I ran a piece of RG-8X from the antenna into the shack and tuned up on 10 meters. The band was semi-open so I called a CQ and was immediately answered. From there on I played DX the rest of the day. By the time the bands went out I had worked about 40 countries, all with nice QSOs. Most impressive for an 18-foot piece of white fiberglass.

On-the-Air

It worked fine on 10 meters. After all, that's right next to 11 meters (the A-99 was originally designed for the Citizens Band). It should work there. The SWR was below 1.2:1 below 29 MHz. The next day I operated on 12 meters (SWR 1.8:1) and was pleased to find that the antenna performed as well on 12 as it did on 10.

Towards the end of the day I became bored with 12 and decided to see what other surprises the A-99 held. I put the rig on 17 meters and heard all kinds of activity—the band was in very good shape.

The antenna loaded with a 2.5:1 SWR. My rig can handle this, but I smoothed it out with a tuner and went to calling CQ. Just like on 10 and 12 meters, I got responses from all over.

To make a long story short, I have now played with this antenna for about four weeks and have found that it works very well on 17 through 10 meters. It won't make it down to 20 meters or below, however.

My testing was done with and without the optional radial kit. I could find no particular difference in performance either way, although there were some very minor changes in the SWR curves.

A Best Kept Secret

In talking with European hams, I discovered that many of them were using CB antennas of one type or another, and that this practice was not only economical but easy as well, and prevented visual intrusion complaints from the neighbors. One chap claimed to have worked 214 countries during the past year with an antenna similar to the A-99.

Could it really be that bigger isn't always better? Could it be that in our search for simple and effective antennas, hams have overlooked the obvious? I doubt if I am crushing any rocks out there in the pile-ups, but I get my share of contacts with this antenna.

Alternatives to Spending $300+

Although most of the competing antennas do offer 20 meter coverage, they also cost two to three hundred dollars more than the A-99. I'm not sure if using 14.313 MHz is worth the extra cost!

High Points

- The recommended retail price for the A-99 antenna is a very modest $74.50 (cheap).
- There are no moving parts on the antenna to wear out.
- It comes in only three pieces which can be assembled in about that number of minutes (simple).
- It can be mounted on the ground, on a mast, or on a roof. I suppose it could even be hidden in a tree. In fact, you can paint it to match the tree if you wish!
- No radials! The entire structure is a little less than 18 feet tall and about an inch in diameter.
- A nice info sheet about installing antennas is included, bringing out some areas of safety that should be revisited from time to time.
- The manufacturer's warranty policy is excellent. If the A-99 fails, it will be repaired or replaced, except in cases of damage or misuse, with no specified time limit.

Recommendations

The A-99 is a very economical and easy means for gaining access to 10–17 meters and getting a good signal out. Feed it with RG-8X for power levels under 200 watts, and RG-8 for higher power levels.

Although I experienced no stray RF problems, I placed an RF choke of six or seven turns of coax about six inches in diameter immediately at the base of the antenna.

You may want to use an antenna tuner to keep the SWR under control for solid-state rigs. If you place the antenna out in the open away from obstructions, you will probably only need a tuner when operating on the 17 meter band. I tried a rig with an internal automatic antenna tuner and found it loaded up easily into the A-99 on any band between 10 and 17 meters. In fact, the automatic tuner made a wonderful companion for the A-99. For a manual tuner, any of the inexpensive tuners should do quite nicely.

By the way, my A-99 is mounted on a 1-1/2 inch diameter galvanized pipe about four feet above ground level, and about 50 feet from the house.

Availability of the A-99

Solarcon has been manufacturing antennas for CB, cellular, and business users since 1975 and distributes worldwide. For the name of a dealer near you, contact Solarcon.

A-99 Specifications

The following is a modified list of specifications which reflect my test results:

Description	Fiberglass-covered vertical antenna
Height	17'8" (separates into 3 sections)
Bands	17–10 meters
Power limits	2 kW
Mounting	1-1/2" mast max.
Grounding	DC grounded
Useful radiation angle	< 20 degrees 10–17 (as plotted with ELNEC)
Radials	Optional, but not needed
Safety	CPSC shock hazard standards to 14,500 volts

Gain: About 0 dBd (unity gain, compared with a dipole)

SWR: < 1.2:1—10m (under 29 MHz) • < 1.8:1—12m • < 2.5:1—17m •

NOTE: The SWR may vary depending on your antenna location.

Showdown in Portland

Discover the thrill of radiosporting.

by Joe Moell KØOV

In an ordinary DX competition, the contestants stay in their shacks in their own countries. They link with each other via the ether for only a few seconds, two at a time. Months later, they read the results in a magazine.

That's fun. But now, imagine an international amateur radio competition where the entrants spend a week together. They stay in one another's homes. They dine in large groups. Their families become good friends.

They challenge each other in the usual time-honored hamshack events, plus Morse contests and radio direction finding "foxhunts." The results are known immediately. There are opening ceremonies and a closing banquet, followed by misty-eyed good-byes.

More fun? You bet. At least 20 dB more, I'd say. Continent-wide radiosporting contests like this have been regular events in Europe and Asia for many years, but they are new to the USA. That's changing, thanks to the Friendship Amateur Radio Society (FARS).

FARS is a not-for-profit organization based in Portland, Oregon. It has a counterpart organization in Khabarovsk, a city of similar size in eastern USSR. Two years ago, hams from Portland went to Khabarovsk for a week of radiosporting activities.

This year it was Portland's turn to host. During the week after Memorial Day, FARS-USA welcomed hams to the second Friendship Radiosport Games (FRG-91). There were all the events usually found at a European/Asian radiosport festival, including DX contests, a CW competition, and the first internationally sanctioned foxhunt in the USA. On hand to compete were 10 Soviet, three Japanese, and 20 US hams.

First, the Foxhunt

In the USA, radio direction finding (RDF) contests are called hidden transmitter hunts, or T-hunts. They involve cars, trucks, and vans outfitted with strange antennas and blinking consoles. It's more like a road rally than a race.

International radiosport RDF, usually called foxhunting, allows no such luxury. It's all done on foot. Speed determines the winner. So, there's no place for the unfit (Photo A).

The site was Portland's Forest Park, a giant wooded labyrinth of trails, trees, and hills. The weather alternated between rain and sun. Somewhere in those 200 rugged acres were five yellow metal boxes, transmitting a few milliwatts on 146.565 MHz. Fox number one came on for one minute, then number two, and so on. To win the event, all you had to do was be the first to find all five, in numerical order, and get back to the start/finish line.

Sound easy? You try it! Even the winners, seasoned Northwest ELT team members and intrepid Southern California T-hunters, got a real workout (Photo B). Since each transmitter is on the air only 20 percent of the time, it's important to plot the bearings to each one often, and carefully triangulate on the maps provided.

Photo B. Kevin Kelly N6QAB won the foxhunt by finding all five transmitters on the two-mile course in less than one and a quarter hours.

It was a dual challenge: Both physical stamina and technical expertise were needed to win. Almost all contestants were headed for the liniment and foot baths after the rigors of this event.

Photo A. Yoshiko Yamagami JQ1LCW is a champion at "fox-teering," as it's called in Japan, but she had never used an American switched-antenna RDF set. Still, she finished fourth out of 15 entrants in the FRG-91 foxhunt.

Round-Robin DX

There was little time for recuperation after the foxhunt: the DX competition was the next day. Five of Portland's best-equipped hamshacks (W7NI, K2RAG, W7EJ, WR7D, and K7RO) rolled out the red carpet to the five international teams.

To insure that no team had an advantage or disadvantage because of the features of a particular station, the teams rotated. Each team spent one hour at each station, with an hour off for travel between operating periods. Thus, the contest period was nine hours, with only five hours actual on-air time.

By now, the competitors sensed that Murphy had connections with Old Sol as well as with the weatherman. Band conditions were anything but hot. Hopes by the Soviets and Japanese of racking up scads of contacts with their homelands were not to be realized (Photo C).

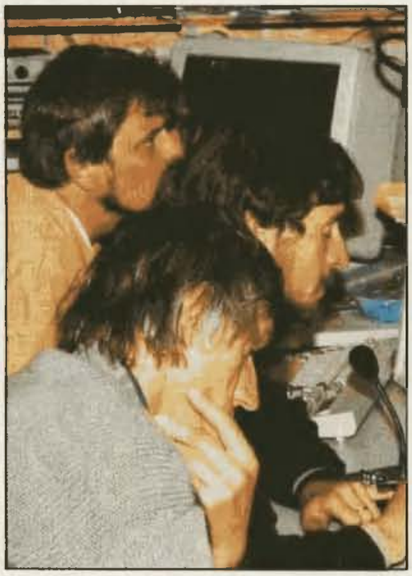

Photo C. These Morse experts on the USSR-Red team made the most CW contacts in FRG-91. They are (front to back) Slava Alexandrov UW0CD, Mikhail Zavarukhin UW0CN, and Igor Krivosheev UA0CZ, in the computer-filled shack of WR7D.

The three-page set of rules for the HF test included "counters" for countries and US/VE/JA prefixes. To insure accuracy, there was a three-QSO penalty for "busted calls," plus additional penalties for incomplete exchanges and invalid QSOs.

All logging was done on computers provided by FARS. The sponsors also provided assistants to enter calls into the computers in real time.

Pressing their home court advantage, US teams took the gold and silver (Photo D). A USSR team was in third place, despite having fewer total QSOs than the Japanese team. The JAs made no CW contacts, which put them at a major disadvantage in the convoluted scoring system.

Speedy Telegraphy

Friday night, it was time to take off to Seaside, Oregon, a coastal vacation spot 80 miles northwest of Portland, for the remainder of the events. The Sea-Pac convention that weekend gave the foreign entrants a chance to meet hundreds of US hams. It also attracted the Northwest's top CW operators to take them on.

After a leisurely practice session at 20 wpm, Mark Sinnard N6OPN cranked up the computer and let the dits and dahs fly for the high-speed receiving test (Photo E). By the end of the 35 wpm round, only three entrants were able to copy for a solid minute. Based on their accuracy in that round, the individual medal winners were selected.

But Mark wasn't through with his torture—it was time for the pile-up contest (Photo F). By this time, hunger and other activities had lured some of the worldclass CW experts out of the FARS room and onto the convention floor. There was a shortage of contestants, so I grabbed a pencil and a set of earphones, and sat down in one of the empty seats.

The pile-up tape began with a plaintive "QRZ DX" by W2NSD/1. (Now where have I heard that call before?) For the next six minutes, it was non-stop CW bedlam ringing in my head, as no less that 101 rare stations called poor Wayne. They were all on top of one another, at varying levels, with lots of noise and QRN mixed in.

What a mess! Somehow I managed to scribble down enough callsigns to stay out of last place. But my list had nowhere near the 34 calls that winner Jim Fenstermaker K9JF got. How does he do it?

There was no lack of entrants for the next event: CW sending. Even Dima Ornatsky, the 12-year-old SWL grandson of RW0CA, gave it a try. The Soviet sending style is much different from the traditional J-38 grasp of American hams.

Russian straight keys have a big knob on them and are placed at the very edge of the table. These fellows used their arms as much as their wrists. They did well, but couldn't top "Faster than Baudot" Dale Jones K5MM.

Photo D. At W7NI's super-station: A good balance of SSB QSOs, CW QSOs, and "counters" captured the gold for the US-Blue team, including Jim Fenstermaker K9JF (left) and Paul Kiesel K7CW (right).

Photo E. Bob Bergert K0PB (left), Dale Jones K5MM (right), and J. Scott Bovitz N6MI (rear table) make fast CW receiving seem easy. Dale took first place and Scott took third.

When the final scores for all events were tallied, there was a tie for the gold between the Red and Blue teams from the USA. The USSR-Blue team took the bronze. But there was no talk of victory or defeat at the awards ceremony, just a celebration of the international camaraderie that amateur radio can provide.

East Meets West

To the Soviets, a trip to a US ham convention must seem like visiting another planet. They come from a country which does no manufacturing of ham gear. Soviet amateurs must build their own sets from whatever parts they can scrounge.

There was little scrounging to be done at the convention, because the Russian ruble is not an international currency. Fortunately, they had brought a few items for sale and barter, which were eagerly snapped up by the convention-goers.

Since the Chernobyl accident and the earth-

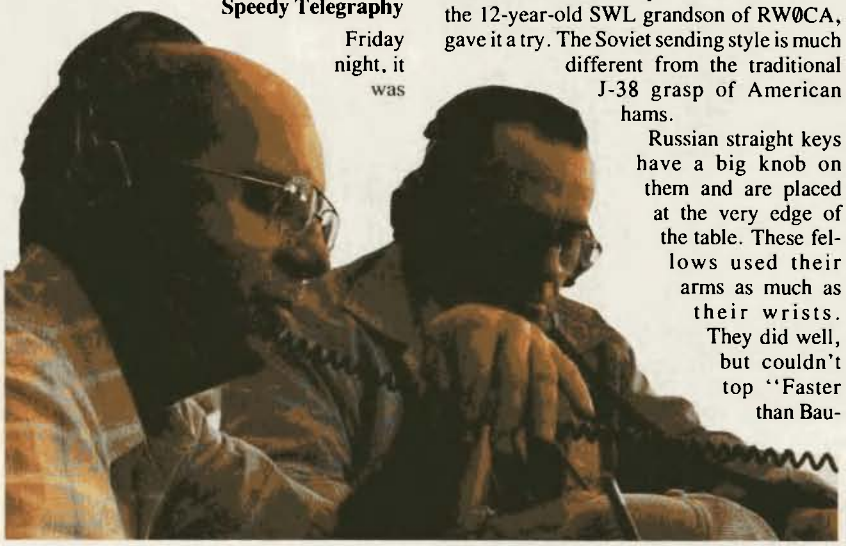

Photo F. Don Calbick W7GB (left) took second place in the brutal CW pile-up test. Harry Lewis W7JWJ (right) won the gold for high speed CW receiving.

quakes in Armenia, Soviet leaders are paying more attention to amateur radio as an emergency communications resource. At a special Sea-Pac convention forum, Mikhail Zavarukhin UW0CN and Gene Shulgin UZ3AU heard how hams in the USA are organized to assist these calamities. Gene is Technical Editor of *Radio*, a Soviet magazine for amateur radio experimenters. He is also Technical Advisor to the Soviet Amateur Radio Emergency Service (SARES). UZ3AU explained that Russian hams would like to emulate our ARES and RACES, but it would be very difficult. Equipment for HF bands is in very short supply. Mobile gear is almost non-existent. He is presently home-brewing some portable sets especially for future disaster use.

On VHF, it's even worse. Two meters is a seldom-used band. Mike and Gene said they knew of only one repeater. It's in Moscow, many miles from recent disaster sites. Shirt-pocket handhelds, an everyday item in the USA, are never seen there.

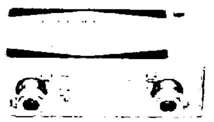
Oregon/Washington area hams want to help, and are collecting equipment and dollars to provide more repeaters for emergency use in the USSR. But Gene cautioned that radio equipment and money should always be sent to SARES by courier. If anything of value is mailed, they warned, it will never arrive at its intended destination.

The future is bright for international radiosporting events. FARS is already planning for the next Friendship Radio Games in Japan in 1993. If you start training now, you could become an internationally famous ham radio athlete! 73

Joe Moell K0OV is the "Homing In" columnist for 73 Amateur Radio Today. He won't walk a mile for a Camel, but he'll drive a thousand miles for a foxhunt. For more information about FARS and radiosporting, send an SASE to Friendship Amateur Radio Society, P.O. Box 13344, Portland, Oregon 97213.

HIGH PERFORMANCE PRESELECTOR-PREAMP

The solution to most interference, intermod, and desense problems in repeater systems.

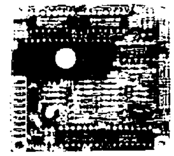


- 40 to 1000 Mhz tuned to your frequency
- 5 large helical resonators
- Very high rejection
- Low noise—high overload resistance
- 8 db gain—ultimate rejection >80 db
- GaAs fet option (above 200 Mhz)
- Cast aluminum enclosure
- N. BNC, and SO239 connector options

Typical rejection:
±600Khz @ 145 Mhz: 28db
±1.6 Mhz @ 220 Mhz: 40db (44db GaAs) ±20 Mhz @ 800 Mhz: 65db
± 5 Mhz @ 450 Mhz: 50db (60db GaAs) ±20 Mhz @ 950 Mhz: 70db

AUTOMATIC IDENTIFIERS

- Up to 8 EPROM programmed messages
- Adjustable audio, speed & interval timer
- "ID over voice inhibit"
- Low power option
- Modular design
- Message selection via binary input—TTL levels
- Size: 2.7 x 2.6 x 0.7"



NEW Model ID-2B

The ID-2B provides required station identification without troublesome diode programming. The "ID over voice inhibit" circuitry allows for courteous operation by not allowing an ID until the next squelch closing.

Microprocessor Repeater Controller, Part II

This month . . . the audio board.

by John Bednar WB3ESS

Last month we looked at the microprocessor repeater controller board. This month, we will discuss the companion audio board which will complete the repeater controller. The audio board, when controlled by the microprocessor board, allows you to select between a variety of different audio sources in a very versatile configuration.

The Audio Board

During the layout of this board it quickly became apparent that there would be too many jumpers on a single-sided board. Therefore, the board was fabricated double-sided without plated through-holes. The latter reduces cost, but makes soldering necessary where traces meet on both board surfaces. Figure 1 is a simple block diagram of the audio board. Though it has many audio inputs and outputs, only a few are used in a basic repeater installation. These extra audio ports allow for future expansion.

The audio board was designed to have a flat frequency response down to about 100 Hz. This should be ideal for those who use discriminator audio from the receivers, and bypass the mike inputs on the transmitters. Depending on the hardware you use, some external frequency tailoring circuits may be necessary. For added convenience, the board was laid out to accept multi-turn pots which can be purchased with top or side adjustments. These pots are placed along the edge of the board so that either pot may be used.

Figure 2 is the schematic for the audio board. Single supply op amps, 4066 audio gates, and CMOS ICs are used throughout. Audio gating is provided so that unsquelched discriminator audio can be used from all receivers. Also provided on this board is a telephone interface, local speaker driver, and PL (private line) gating logic. The PL logic allows simple installation of PL to the repeater. The circuits on the board allow the repeater receiver audio to be gated to the phone, repeater transmitter, or link transmitter. Similarly, the link and auxiliary audio inputs are gated and connected to the three audio outputs. For added flexibility, a simple summing input was added at each output op amp for summing ID tone generators or any other capacitively coupled source. With all these input and output ports available, the framework for expansion is already in place.

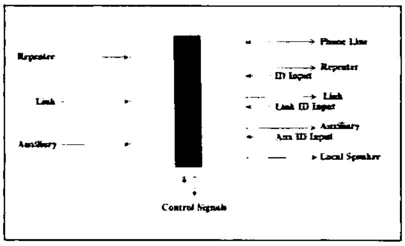

Figure 1. Audio board block diagram.

Audio Board Parts List

C1,11	0.047 µF ceramic	Digi-Key P4521
C2,7,14	0.1 µF ceramic	Mouser 140-CD12R6-104Z
C3,4,5,12	0.22 µF ceramic	Digi-Key P4529

Card-Edge connector 31/62	Solder eyelet with mounting holes	Digi-Key S1312
Alternate connector	solder tail, no mounting holes	Radio Shack 276-1453

Notes: 1. All resistors are 1/4W unless specified otherwise. 2. For side adjust pots, order part number CFG15; for top adjust pots, order CEG15. 3. If IC sockets are used, be sure to purchase sockets that have long enough leads so that the traces under the sockets can be soldered on the top surface of the board. 4. Parts are available from Digi-Key Corp., 701 Brooks Ave. S., P.O. Box 677, Thief River Falls MN 56701-0677. Tel. (800) 344-4539. Mouser Electronics, 12 Emery Ave., Randolph NJ 07869. Tel. (800) 346-6873.

Etched and drilled microprocessor and audio PC boards are available for $19 each from John Bednar WB3ESS at 548 Cherryville Road, Northampton PA 18067. John can also supply a pre-programmed 8749H microcontroller IC for $19 (please indicate the repeater call as you want it sent, including the prefix "de" and suffix "/rpt" along with all spaces clearly marked). A limited supply of SSI202 touch-tone decoder ICs are available for $7. Please add $4 shipping for all orders. Foreign orders should include additional postage.

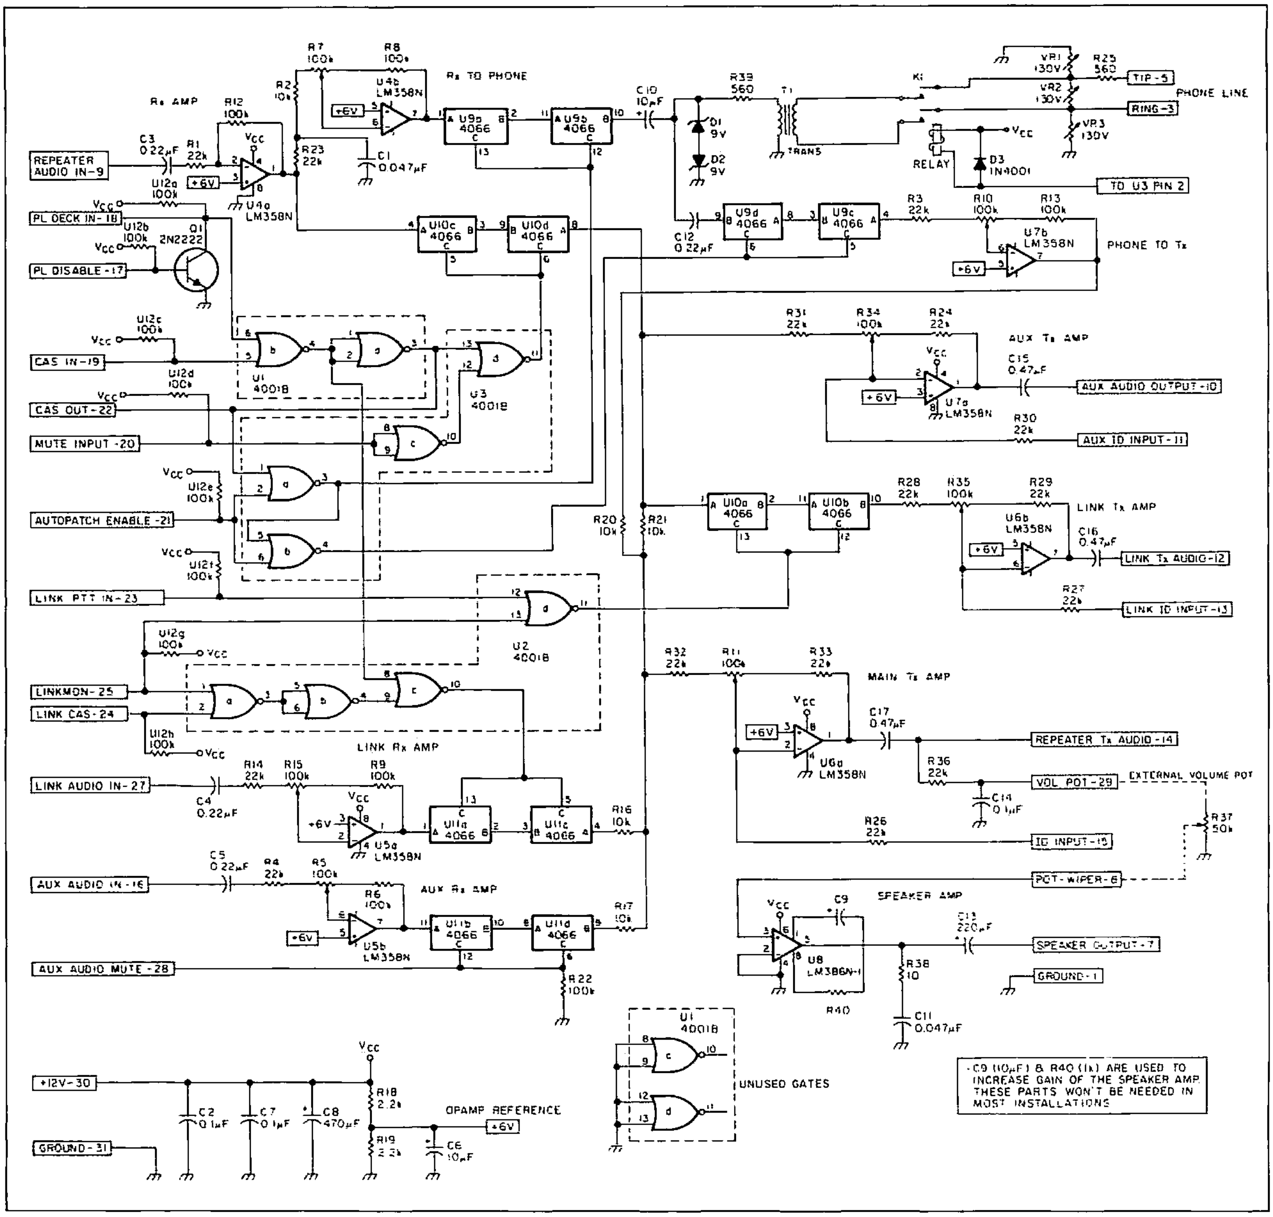

Figure 2. Schematic for the audio board.

For those repeaters without PL, pin 17 on the audio can be left disconnected and the repeater will function normally. To install PL on the repeater, connect an open collector output from a PL deck to the PL DECK IN pin of the audio board and a computer output to the PL DISABLE pin. Apply power, ground, and audio to the PL deck and the installation is complete. Remember, output #9 is ideal for this because the courtesy beep changes to let our users know that PL is required to use the repeater. When the repeater controller initially powers up, the computer board outputs are HIGH; therefore, PL will not be needed to initially operate the repeater. When the output is programmed low, the PL deck output will be gated with the receiver CAS to derive the CAS OUT signal for the computer board. When enabled, PL will be required for all repeater operation, including the entry of DTMF commands.

The speaker amplifier has an output power of approximately 0.5 watts into 8 ohms. Several owners have noticed that some LM386N ICs are unstable if the device input isn't connected to the volume control. Therefore, if you don't plan to use the speaker output, don't bother installing IC U8. The volume control (R37) is not located on the audio board because it's intended to be installed at a convenient location for speaker level adjustment.

How It Works

Although the audio board has many audio paths, its operation is fundamental. All op amps operate around a +6 volt DC reference applied to the noninverting pin of each amplifier. Capacitors are used at almost every input and output to interface to receivers and transmitters. An exception to this are the three ID inputs where external coupling capacitors *are* required. The computer board used one of these ID inputs, however the coupling capacitor is already present on that board.

The primary audio path is from the repeater receiver through to the transmitter. The main repeater receiver audio is connected to pin 9 of the board. Input amplifier (U4A) has a fixed gain of 4.5 which can be changed by varying resistor R12. The receiver audio is then passed through two series audio gates (U10C and U10D) which are controlled by three signals (the CAS IN, the MUTE signal from the computer board, and the PL DECK IN signal). Whenever the voltage is near zero on the control pin of any audio gate (pins 5 and 6 here), the audio is muted or switched off. When the audio passes through the audio gate (U10C and U10D), it then goes to three amplifiers (U6A, U6B, and U7A) and the speaker amplifier U8. Each output has an

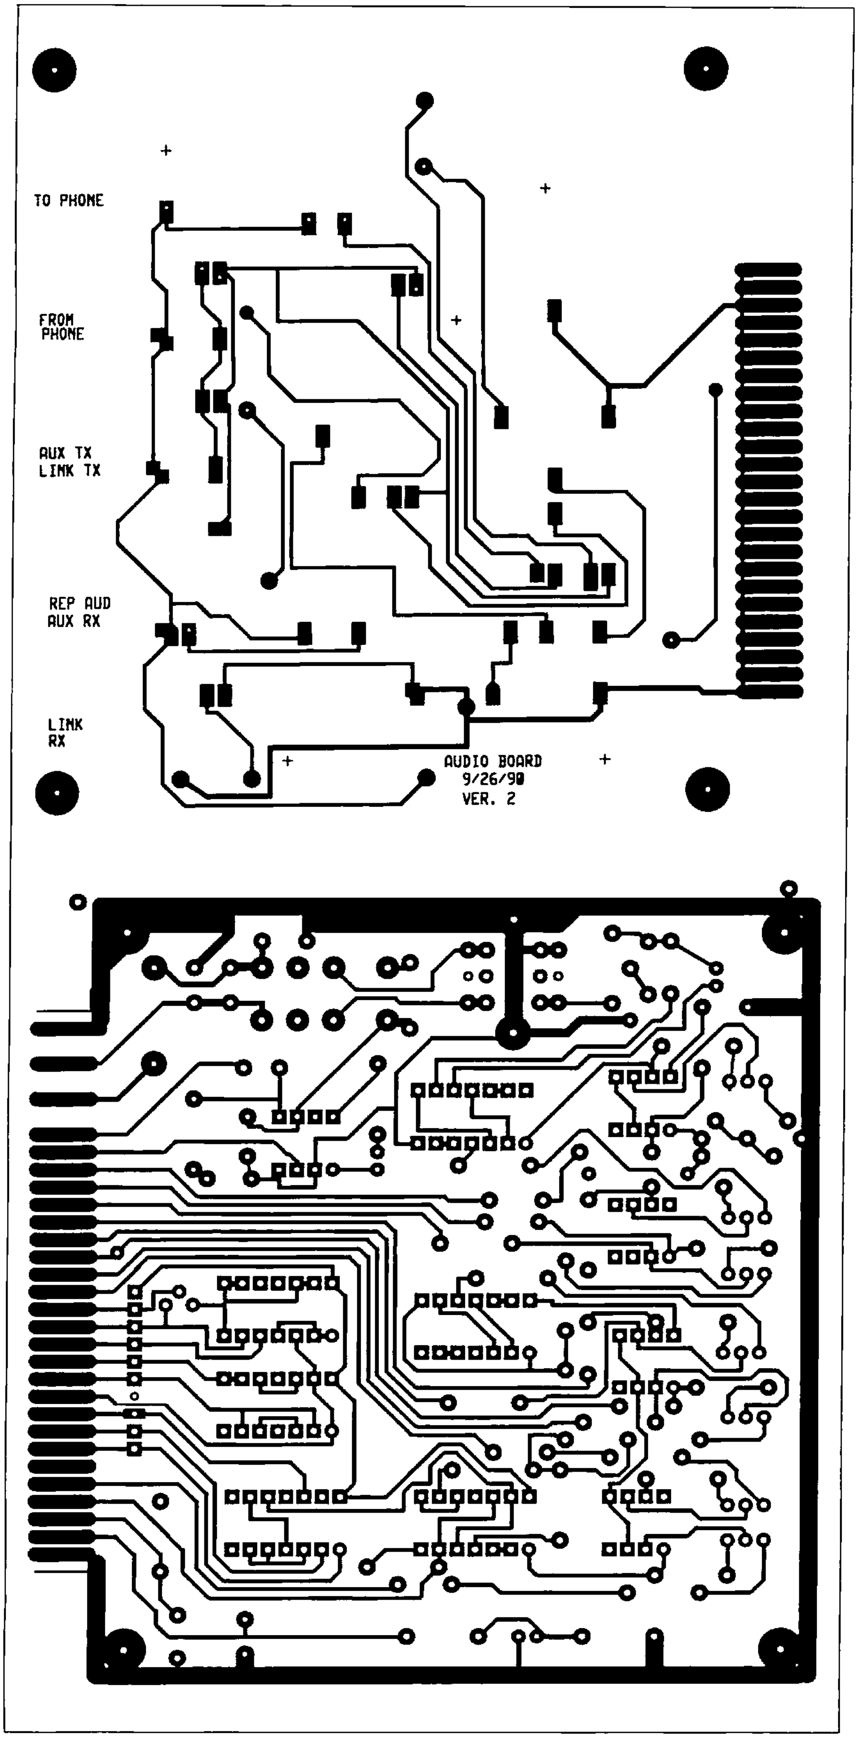

Figure 3. PC foil patterns for the audio board. (a) Top layer. (b) Bottom layer.

individual gain adjustment so each one can be adjusted separately.

The receiver audio from the input amplifier (U4A) also passes through an RC filter (R23/C1) to the adjustable phone amplifier (U4B). The gain of this stage is controlled by pot R7. If needed, the gain can be increased or decreased by changing the fixed resistor R8. The audio from op amp U4B is then passed through an audio gate to the telephone transformer. This audio gate is controlled by the receiver CAS IN signal, and the AUTOPATCH ENABLE from the computer board. When both the CAS OUT and the AUTOPATCH ENABLE signals are LOW, the audio from U4B is passed through to the telephone. Audio from the telephone is gated by U9C and U9D before passing to op amp U7B. The output of this op amp is connected to the main transmitter mixer which feeds the repeater transmitter and local speaker. The phone line is connected to the audio board with relay K1. It is controlled by the AUTOPATCH ENABLE signal. The audio board phone interface is protected by the 130 volt MOVs (VR1, VR2, and VR3), zener diodes (D1 and D2), and resistors (R39 and R25).

The remaining audio inputs LINK AUDIO IN and AUX AUDIO IN are similar to the repeater input, only differing in what controls the gate pin of the audio gates. Both of these inputs have an adjustable amplifier with individual pots. Similar to the other stages, the gain can be varied further by changing the fixed feedback resistor (R9 and R6) in each stage. The audio from these inputs is connected to the main transmit mixer.

The speaker volume pot is connected to the output of the main transmit op amp U6A. An RC filter (R36 and C14) is provided to roll off the audio for a natural sounding response. If necessary, capacitor C14 can be varied to make the speaker audio sound pleasant. The wiper of the volume pot feeds the speaker amplifier (U8) which can drive an 8 ohm speaker. Holes are provided in the circuit board for additional components (R38 and C11) to increase the gain of this speaker amplifier if necessary. I don't think these parts will be necessary in most installations.

Assembly

Before you begin assembly, here are some tips:

- Use a LOW TEMPERATURE soldering iron. Do not attempt to assemble this board with a high temperature soldering iron or gun.
- Like the computer board, watch out for an incorrect resistor SIP.
- You cannot install the telephone transformer and the MOVs backwards.
- All traces must be soldered on both sides of the board. The holes are not plated through.

Begin assembly by installing the components that have traces on the top side of the board. If sockets are used, make sure you leave enough room under the socket to solder the top board pads. Next, install the two jumpers. One jumper is near R1 and the other is near the common end of resistor pack U12.

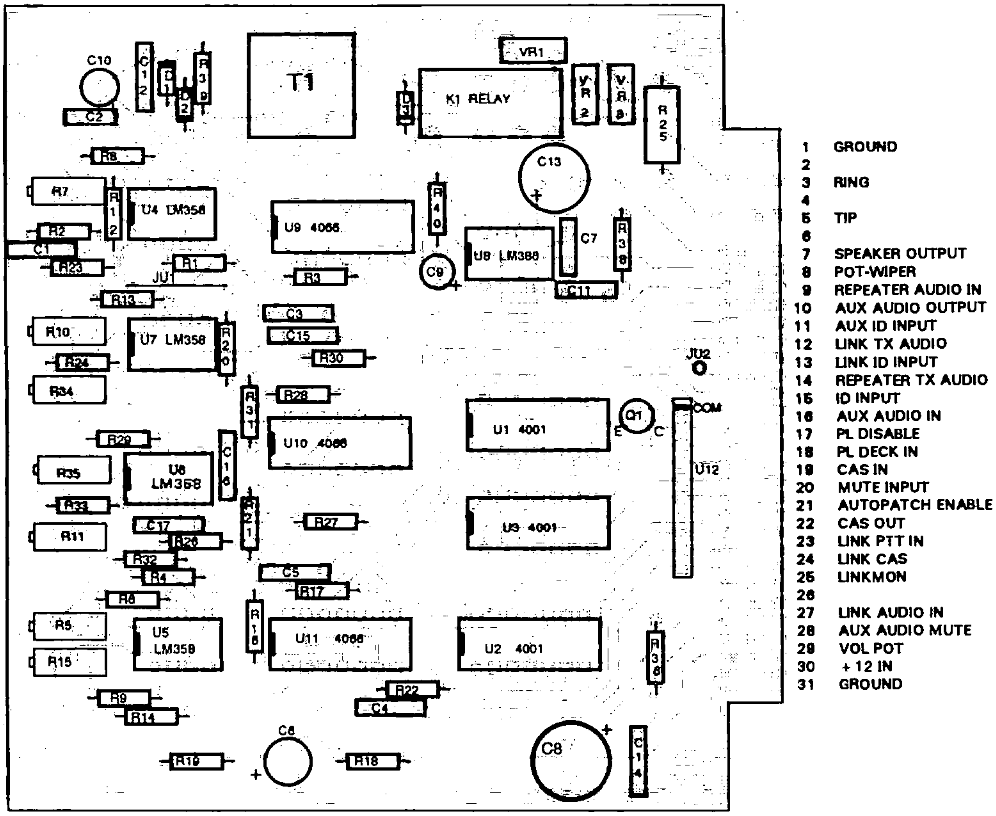

Figure 4. Parts placement for the audio board.

Complete the board by installing the remaining components.

Adjustments

See the diagram in Part I in the October 1991 issue. It shows the necessary connections to the audio board for a simple repeater installation. For simplicity, power and ground connections to both boards were omitted. The first test is to power up the repeater controller and listen for the power up ID on the speaker or the repeater transmitter. If necessary, the ID level may be adjusted with R20 on the computer board. Next, adjust the audio path from the repeater receiver through to the transmitter with R11. If there isn't enough gain, increase the feedback resistor (R12) of U4A to about 330–500k ohms. If too much audio is the problem, an external resistor divider should be used to pad down the level.

Once the main repeater path is adjusted properly, the ID level can be readjust-

EMOTATOR

A NEW GENERATION OF ROTATORS ARE OUT TO SET HIGH STANDARDS!

EMOTATOR! THEY SUPPLY OVER 60% OF THE JAPANESE MARKET WITH THESE INNOVATIVE FEATURES:

- LARGE MACHINED STEEL GEARS
- ADJUSTABLE CENTERING MAST CLAMP
- CAST AND MACHINED ALUMINUM CASES
- PRESET AND COMPUTER CONTROL
- SOLID STATE CONTROLLERS FOR SMOOTH START AND STOP, USING 7 CONDUCTOR WIRE
- FRICTION BRAKING
- CIRCULAR POSITION INDICATORS
- LONG TERM RELIABILITY

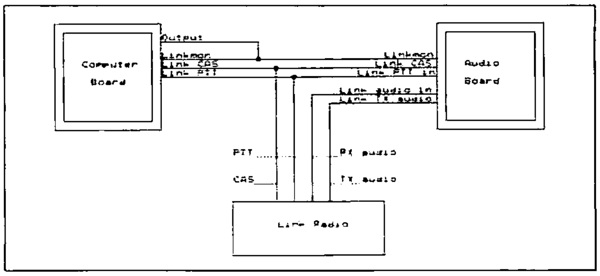

Figure 5. Block diagram of modifications to add a basic link to the repeater controller.

ed to the correct level. Follow this by adjusting the DTMF decoder level on the computer board. To set this level, simply transmit a DTMF digit and turn R17, on the computer board, 20% past the point where LED DS1 lights. If you notice that some digits light the LED and others don't, try increasing the level a little. If the increase in level doesn't help, the frequency response from the receiver isn't proper. On the computer board, try removing one end of C8 and/or C18 to see if an improvement in decoding can be made. If the operation gets worse, the values of C8 and/or C18 may have to be increased. If additional gain is needed for the DTMF amplifier, the value of R18 can be lowered to increase the gain. For reference, the SSI202 touchtone decoder will function with 15–20 mV rms of audio. This was measured from U3, pin 9, to ground while transmitting digit #1.

At this point, the repeater should function and DTMF commands may be entered. The final adjustments on the audio board involve setting the autopatch levels. Turn on the autopatch and adjust R10 for proper level from the phone line to the repeater transmitter. Next adjust R7 for proper levels to the phone line. If either adjustment is out of range, increase or decrease the appropriate feedback resistor (R8 or R13), to vary the the gain of the op amp. This should complete the adjustments necessary for a repeater with autopatch.

If the link or auxiliary ports are used on the audio board, the adjustments are identical to what has previously been done. Remember, the feedback resistor in each stage can be changed if needed. Before adjusting link audio, the LINKMON input will have to be pulled LOW for the audio gating to work properly. Also, the auxiliary audio input has a control signal which is connected to pin 28. This pin will have to be pulled HIGH (12 volts) for audio to pass through the audio gate directly after the op amp.

Adding Links

There are two methods of adding a link to this repeater controller. The first method is simple and requires little extra hardware, while the second method offers many advanced features, like being able to activate the link from the link frequency! This repeater controller was optimized for a single

NEW

Line of
NO-GROUND-ANTENNAE

ANT-Ventures presents a new concept in VHF mobile antennae. The unique design allows these antennae to function efficiently WITHOUT A GROUND PLANE. Perfect for use on those vehicles with plastic or fiberglass bodies. Great for portable or apartment use, these antennae can be mounted to wood or metal and also directly to the back of your radio.

Pre-tuned at the factory, these antennae provide operation across their designed band, with a VSWR better than 1.5:1 and a power rating of 200 watts. MARS/CAP operation is possible without retuning.

Model NG-144-1 mounts directly onto a SO239 connector and model NG-144-2 mounts into standard 3/8 mounts which are optionally available from us.

CIRCLE 43 ON READER SERVICE CARD

link or remote base. Adding multiple links is possible, but the external hardware must be built to switch the control and audio signals.

To add a simple remote base to the basic repeater, see Figure 5. There are only a few extra connections that have to be made to add this type of remote. A small amount of interfacing may have to be done to connect the PTT and CAS lines to the repeater controller. Although this is very attractive, the link can only be turned on and off from the repeater, plus there will be no ID on the link frequency. Also, before using the autopatch, the link will have to be turned off manually.

With some extra hardware, the link installation can be upgraded to address all of the above concerns plus add more features. This method incorporates the Link Controller, a previous project which appeared in the December '89 issue of *QST* ("A Repeater Linking Controller"). To make interfacing to the Link Controller easy, this repeater controller has several dedicated outputs. A diagram of this type of link can be found in Figure 6. Similar to the previous figure, it only shows the connections that have to be added to the basic repeater diagram. With only a few extra connections and a Link Controller board, the simple link can be upgraded to add features not found on the kilo-buck repeater controllers.

Ideas and Expansion Circuits

This section is a combination of ideas and suggestions for expanding the repeater controller. Some of these ideas have come from owners using the controller. I invite others to expand on these topics and submit their circuits to *73 Magazine* for others to use.

• A simple timer circuit may be built to add an autopatch timer to the repeater controller. Input #2 provides a way to remotely terminate the autopatch.

• Similarly, a long distance lockout circuit can be constructed to terminate the patch if a long distance number is dialed. An output pin from the computer board can be used to defeat this feature when long distance dialing is allowed.

• The superuser input pin on the computer board can be connected to a variety of sources. One interesting idea is to connect it to the output of a PL decoder. The owner would turn on PL while transmitting to enter superuser commands. Really sneaky, huh?

• If an output pin is connected to the superuser pin, an input pin can be connected directly to the superuser pin for a status readback of the DTMF priority. That way, owners can prompt the repeater controller to see what mode the controller is in.

• If the repeater doesn't have a link, the link courtesy beep can be used by connecting an unused output to the LINKMON input. By programming the output low, the link courtesy beep will be turned on. At the same time, the link PTT pin from the computer board will become active. This output can be used to key a PL encoder. With this connection, PL will be encoded on the repeater when a user is transmitting. Great for those handhelds that decode PL.

• The MUTE output from the computer board can be used to key a DTMF cover tone oscillator. The output of this oscillator can be fed into the ID INPUT on the audio board.

• The MUTE output signal with some logic can also be used to unkey the link transmitter while touchtones are being entered.

While writing this manuscript, I quickly became aware that this wasn't going to be a short article. In addition to what has already been presented here, I have generated two additional documents. One describes the controller commands in more detail, while the other provides a detailed functional pin-out description of each board. *[See author's address below.]*

I would like to acknowledge two people who assisted in this repeater controller project. Gary N3ECW coordinated the manufacture of both circuit boards, assembled all PC board models, and evaluated the performance of the completed audio board. In addition, Mike N3DZM provided considerable input during the design phase of the audio board. He also built the hand-wired audio board prototype, debugged it, and made the first repeater installation of this controller. Since a project like this takes so much time to complete, without Gary and Mike's help, it would certainly have taken much longer. ■

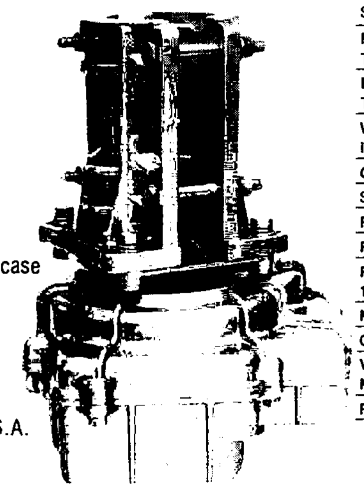
CREATE is serious about long term reliability. The CREATE RC5 series rotators were designed with the serious DX'er in mind. Three models for medium, large and ultra large antenna arrays are available.



RC5-3

Features of the RC5 series:

* Cast and machined aluminum case
* Worm drive brake gearing
* Mast clamp guides
* Reverse delay control (RDC)
* Preset (on 3 models)
* Circular dial indicator
* Circle overlay available for U.S.A. (west - central - east)
* Long term reliability

Create CK46 Mast Bearing with strong anti-corrosion features also available.

A Simple 10-Meter Sideband Amplifier

Give your QRP rig a boost.

by Bruce Auld NZ5G

This sideband amplifier project is intended as a sequel to "A 10M Sideband Transmitter" (*73 Amateur Radio Today*, October 1991, page 14). It will give the rig a fighting chance among the crowds that we experience, even on 10 meters.

This amplifier generates between 5 and 10 watts PEP on 10 meters, depending on the input power, using a single 2SC1969 transistor, which is an inexpensive plastic device. In my version of the amplifier, 10 watts was available with an input of about 1.25 watts. When input power drops to 0.75 watts, the output drops to about 5 watts. The transmitter this is designed for should deliver between 0.75 and 1.0 watts PEP, depending on construction methods and the parts used.

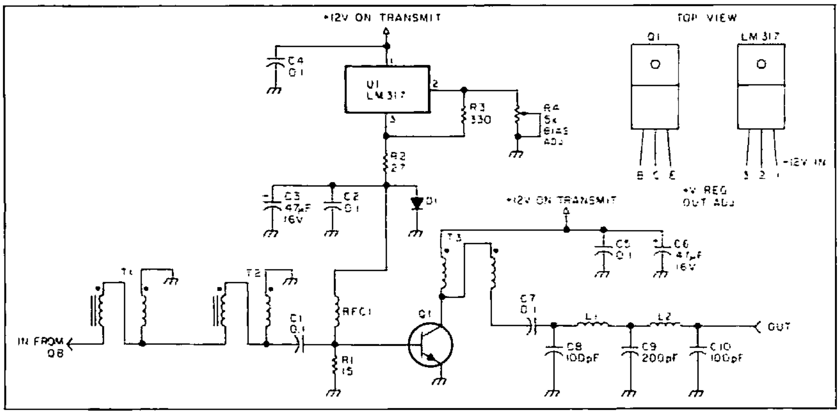

Figure 1. Schematic diagram of the amplifier.

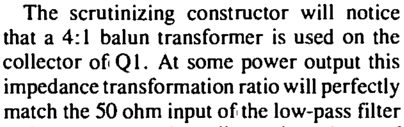

Figure 2. If you don't use an etched PC board you can make your own mounting pads and solder them to blank PC board material as shown.

Figure 1 is the schematic diagram of the amplifier. It is intentionally broadbanded, with two cascaded 4:1 transformers at the input to step the impedance down, and one 4:1 transformer at the output (see Figure 6 for winding details of T1, T2 and T3). The only components which are frequency-dependent are the LC combinations which make up the low-pass filter at the output. If you would like to construct this amplifier for other bands, only the low-pass filter components LI, L2, CI, C2 and C3 need to be changed (see Table 1).

The necessary forward bias for Q1 (0.7 volts) is set by D1, a garden-variety rectifier diode. I chose to use the LM 317 adjustable voltage regulator to drop the 12 volt supply down to around 5 volts before feeding it to the diode. Some circuits call for a single power resistor of 100 ohms or so in place of U1, but it must be rated at 10 watts or more because it dissipates a tremendous amount of heat. The circuit I used stays quite cool.

The scrutinizing constructor will notice that a 4:1 balun transformer is used on the collector of Q1. At some power output this impedance transformation ratio will perfectly match the 50 ohm input of the low-pass filter and the antenna. The collector impedance of this type of circuit is found by the following formula: $\mathbf{Z = Vcc^2 / 2 \cdot PO}$, where **Z** is the impedance, **Vcc** is the supply voltage, and **PO** is the power output. Applying the formula to the power outputs possible, you will see that at 5 watts, collector impedance is 14 ohms; and at 10 watts it is 7 ohms. Consequently, if the amplifier is to run at a power higher in the range specified, a 9:1 transformer may better match the collector to the low-pass filter. As a practical matter, I have tried 4:1, 9:1 and 16:1 transformers at this point with equal result. Solely for the sake of simplicity, I chose the former. Your application may justify another transformer.

Construction

Construction is performed over a ground plane of printed circuit board material, cutting out a small rectangular hole to accommodate the body of Q1. In my version of the amplifier, Q1 is mounted against the back wall of the transmitter, which acts as a heat sink. Because the tab of the transistor is common to the collector, insulate it from the chassis with a mica wafer. Do not forget silicon grease at this union to enhance heat transfer. I used the "ugly" construction method, mounting components on top of the board between half-inch square islands of double-sided PC board material affixed to the board. These pads can be fashioned easily with a hacksaw or hobbyist's drill with a cutting wheel, then soldered on the board, first by tinning the underside of the pad and its site on the board. Next, lay the soldering iron on the site to heat it and hold the underside of the pad on the topside of the soldering iron. When both surfaces are hot (two seconds will do), quickly remove the soldering iron and lay the pad on its site. The joint cools almost instantaneously and forms a permanent bond. I found that temporarily soldering a half-watt resistor to the top of the pad makes a nice "handle" for easy manipulation of the pad and precise placement on its intended site on the board (see Figure 2).

While I preferred not to use the conventional ferric chloride etching technique, those desiring an etched board may prepare the board by masking the entire board with tape or rubber cement and carving out narrow borders around the pads, exposing them to the etching solution. Figure 3 shows the foil pattern of the board and Figure 4 is the parts placement guide. A layout similar to this was

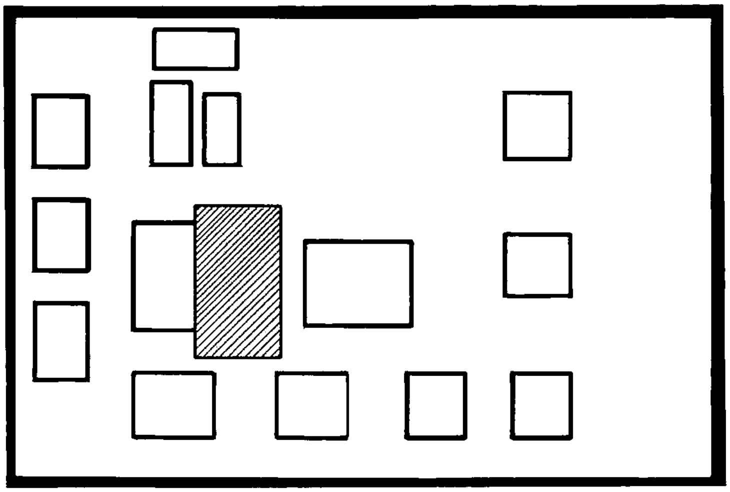

Figure 3. PC board foil pattern. Note: Dark lines are etched areas.

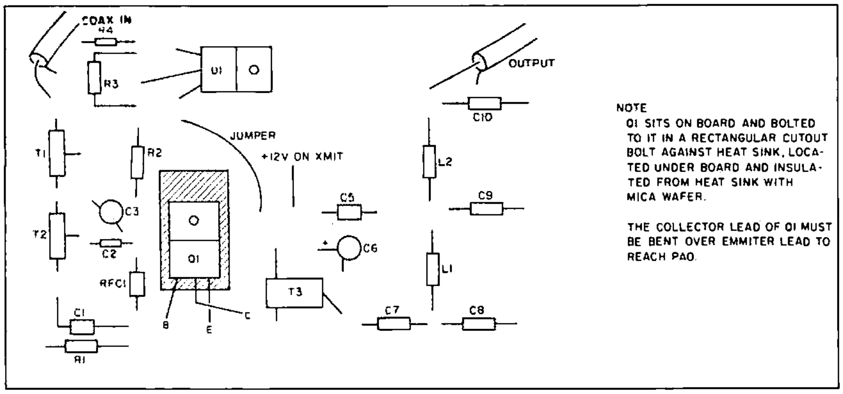

Figure 4. Amplifier parts placement. Cut out the shaded area of the PC board under Q1.

described in detail by Bill Heishman in his article "MOuSeFEet" (*73 Amateur Radio Today*, November 1990, page 36), with a full-size etching pattern. It is easily adapted to this purpose.

The supply voltage may be applied to the collector of Q1 continuously because the transistor is turned "off" until bias (from U1) and RF drive are applied. Consequently, the bias voltage is applied only during transmit periods. This keyed voltage may be obtained from relay K1 on the transmitter amplifier board. There is a PC solder pad and hole for this purpose.

In order to place the amplifier "in service," you must decide whether to leave it in-line permanently, or whether you want the option to switch it in and out to achieve high and low power output for your transmitter. If you prefer it in-line continuously, simply route the transmitter output (after the low-pass filter, but ahead of the antenna relay) to the amplifier, and the output of the amplifier to the relay. It is as simple as adding another stage of amplification to the transmitter. If you prefer selectable power levels, install the amplifier the same way, but include a double-pole, double-throw toggle switch between the transmitter low-pass filter and the amplifier input, as described below (see Figure 5).

Tune Up and Operation

Tune up and operation are simple. First, with transmit voltage applied to U1, but no RF drive, adjust the voltage appearing at pin 3 of U1 to approximately 5 volts. Next, confirm that D1 is properly limiting the voltage at the base of Q1 to 0.7 volts. Apply drive from the transmitter and check the output with a wattmeter. As with the transmitter, squeeze together or spread apart the turns of coils L1 and L2 in the low-pass filter of the amplifier for highest output.

I noticed that the system as a whole was less tolerant of impedance mismatches between stages and imprecise adjustments in the various stages in general. Oscillations appeared in the transmitted signal that were not present at the 1 watt level that originated in the transmitter. This glitch disappeared by making more precise adjustments in the transmitter. I recommend reducing audio drive with R27 and reducing the input to the mixer by rotating Q5's trimpot, R15. Also, readjust all the

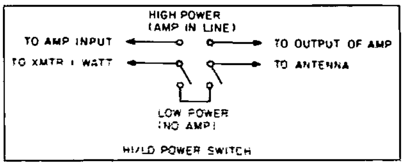

Figure 5. A double-pole double-throw switch can be used to switch the amplifier in and out of the circuit.

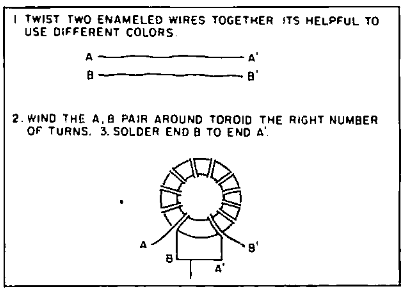

Figure 6. Bifilar winding details for T1, T2 and T3.

Table 1. Output filter values for other bands.

Band (meters)	C1,C3	C2	L1,L2
12	117 pF	220 pF	8 turns, T-50-6 toroid
15	138 pF	270 pF	9 turns, T-50-6 toroid
20	138 pF	420 pF	12 turns, T-50-6 toroid
30	289 pF	579 pF	12 turns, T-50-2 toroid
40	400 pF	800 pF	14 turns, T-50-2 toroid
80	700 pF	1415 pF	19 turns, T-50-2 toroid

Note: use #26 wire for C1 and C2. Use capacitors that are closest to these suggested values. As the operating frequency decreases, the gain will increase as well as the possibility for instability. You may have to use RC feedback to negate this effect. Values for the above table were obtained from the QRP Notebook by Doug DeMaw.

trimmers in the completed transmitter to achieve a good balance in the system as a whole. Listen to your voice in the station receiver and you will be rewarded with a cleaner signal.

On-the-air tests were gratifying. While true QRP operation is a lot of fun, a little punch in your signal will enhance its readability and produce longer and more enjoyable contacts. I found that contacts with armchair copy were easy to make. Of course, it's always the best policy to use less power when it will suffice, but no one will suggest you are using overpower on the ham bands at 10 watts! Happy home-brew DXing! ■

Table 2. Parts List

Part	Description
U1	LM317 variable voltage regulator
Q1	2SC1969 power transistor
RFC1	10 turns on an FT-37-43 toroid
T1,T2,T3	10 turns #26 wire, bifilar wound on an FT-50-43 toroid (an FT-37-43 can be used for T1 & T2)
D1	1N4001 rectifier diode or equiv.
L1,L2	8 turns #26 wire on a T-50-6 toroid
C1,C2,C4,C5,C7	0.1µF/50V ceramic capacitor
C3,C6	47µF/16V electrolytic capacitor
C8,C10	100 pF ceramic capacitor
C9	200 pF ceramic capacitor
R1	15 ohm resistor
R2	27 ohm resistor
R3	330 ohm resistor
R4	5k PC mount potentiometer

An etched PC board is available for $6 + $1.50 shipping per order from FAR Circuits, 18N640 Field Court, Dundee IL 60118.

Toroids and other components can be obtained from Tanner Electronics, 1301 West Beltline Rd., Suite 105, Carrollton TX 75006. Tel. (214) 242–8702. Radiokit, P.O. Box 973, Pelham NH 03076. Tel. The 4066 IC

Several months ago, I mentioned using a 4066 IC for audio muting in the HW-9. This IC was put to good use by Paul Levesque KB1MJ. It occurred to me that many people who design their own gear might not know about this very versatile chip.

So, just what is a 4066, anyway? Well, it's a quad analog switch. Basically, it's just four CMOS switches that can be turned on or off by putting a voltage on a control line. With zero volts on this line, the switch is open. Apply more than half the supply voltage on the control line, and the switch turns on. The "on" resistance is anywhere from 80 to 270 ohms.

The 4066 can pass DC for switching, RIT circuits, and, of course, relays. The 4066 can also pass audio with low distortion, and handles RF up to 40 MHz. You can switch it on and off up to 10 MHz. The low current demands make this a QRP potable rig-builder's dream come true—only 0.5 microamps. The peak switching voltage must not be higher than the supply voltage, however. There are current limits flowing through the switches.

Since there are four switches in one 4066, any leftover switches can be used to control other circuits instead of transistor switches. Relay drivers and LEDs come to mind. If you don't need them for this, you can wire up the leftover switches in parallel for more current capacity. You might want to do this if you use a T/R relay with a coil resistance under 300 ohms.

The 4066 IC might be the chip you're looking for if you're into QSK transceivers. A pair of small reed relays could do all the RF switching, with the 4066 doing the DC and audio switching.

Because the 4066 is a CMOS device, it is easily damaged by static unless buffered. Most of the CMOS chips made today are buffered, but beware of the surplus ICs, and, of course, ICs from old computer boards. Keep static away from the chip, and you'll have no trouble. Also, with any CMOS chip, all unused inputs should be tied to either ground or Vcc. Don't let them float!

The 4066 can be purchased for about 60¢. Radio Shack stocks the 4066 at a slightly higher price. See Figure 1 for various uses of the 4066.

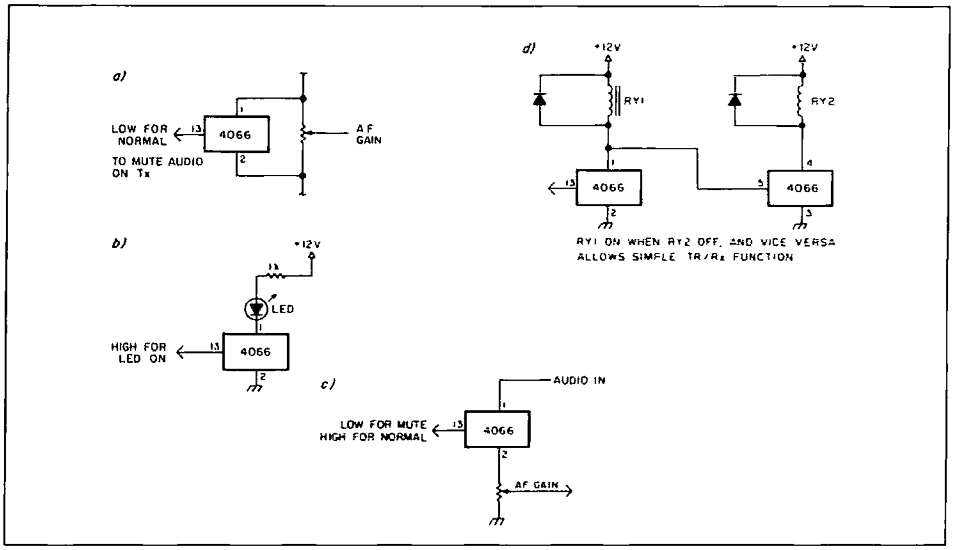

Figure 1. The 4066 IC can be used in a number of ways.

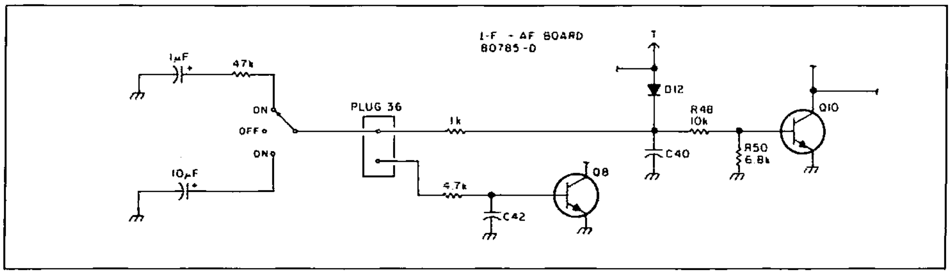

Figure 2. The break-in delay for the Argosy is determined by C40 in the AF-IF board.

Argosy Break-In Delay Mods

In the past, I've had modifications for the Heath QRP rigs. Now I've got several this month for the Ten-Tec Argosy.

Anyone who has used the Argosy knows that there is no RF gain control. But don't get ahead of me—this isn't a modification to add either an RF gain control or RF attenuator. Instead, this modification slows down the QSK during periods of high QRM or QRN. It would be especially helpful during a CW contest. The "thumping" in the headphones is greatly reduced with this modification (see Figure 2).

The modification gives three types of break-in delay: A slightly extended break-in to reduce the "thumping"; normal, full break-in; or the semi-break-in delay, as used on the Corsair.

The break-in delay is determined by C40 in the AF-IF board. This is a 1 µF electrolytic capacitor. Also on this board is plug 36, which has a spare unused pin.

To carry out the modification, first cut the PC trace between the two pins of plug 36. Solder a 1k ohm resistor from the positive end of C40 to the unused pin on plug 36. This resistor should be on the underside of the board.

Drill a 1/4" hole on the rear panel next to the HI/LO power switch. A small toggle switch of the ON-OFF-ON type is required. Wire this switch as shown in Figure 2. A large solder lug around the switch's shaft will make a convenient place to ground the required resistors. By selecting the value of the capacitor, you change the delay break-in time constant.

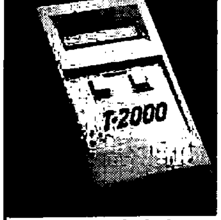
A word of caution. If you don't know what you're doing, don't attempt this modification. Anytime you have to cut traces, be sure to measure twice, cut once! I have not done this modification to my Argosy, so do so at your own risk.

To reduce the amount of RIT offset in the Argosy, here's a simple mod that requires only one additional part—a resistor.

Wire a 15k resistor across the RIT control. This will reduce the offset to about +2.9 kHz to −3.1 kHz. This is a great way to fine tune the RIT; makes it so much easier to tune in a signal when using the narrow crystal filters.

Next month we'll visit the shack of a DXer and QRPer, all rolled into one. The Pulse Charger was such a success that I have made up more kits of the PC board and parts. It's still $29.95 plus $2.50 for postage. It would be a great project for the coming winter months.

TOUCH TONE DECODER:



Decodes DTMF tones from audio source, (tape, phone, radio). Displays numbers on LCD display, 120 Digit memory. $169.00 ppd. U.S.A.

The Amateur Television Network

What do you do if you are surrounded by 5000-foot (or higher) mountains? You plant ATV repeaters on top of them, of course! In Southern California you're never out of reach of at least one of the many machines that cover the region. Over the past few years a group called ATN (the Amateur Television Network) has been undertaking an ambitious effort to link some of these repeaters together to form a wide-area system.

The first repeater in the network is the WA6SVT machine with an input on 434 MHz (426.25 alternate) and an output on 1253.25 MHz. It is located on top of 5670-foot Santiago Peak. Its location, southeast of Los Angeles, covers most of the Los Angeles basin and the San Bernadino/Riverside valleys, most of the San Gabriel valley, as well as a good deal of San Diego county.

Linking it All Together

Mike K6ZSR and Mark NU6X started a repeater project to fill in coverage in the San Fernando Valley and parts of Ventura County. With an output on 919.25 MHz, it was the first repeater (of any kind) to use the new 900 MHz band. It's located on top of Oat Mountain, near Chatsworth. The Oat machine was the first to be linked up to Santiago Peak (although it's currently a one-way link from Santiago). The Oat machine operates as a normal ATV repeater if someone is transmitting on its 434 MHz input. If the Oat repeater is idle and the Santiago repeater is up and running, a 1253.25 MHz receiver at the Oat Mountain site links this to Oat's output on 919.25 MHz. That way anyone in the San Fernando Valley can watch what is going on in the rest of the ATN system.

The third repeater in the network is the WB6VVV/WA6SVT machine on Job's Peak (near Crestline) high above San Bernadino. This machine uses the same 919.25 MHz output as the Oat repeater. A number of mountains (as well as a fair distance) separate the two machines, so there is no interference problem. This machine is a key factor to linking into the Mojave Desert and beyond. Not only can it be linked to the Santiago Peak machine (in the same manner as the Oat repeater), but an ambitious project has been undertaken to use this machine to link all the way into Las Vegas, Nevada!

The Las Vegas Connection

Geoff KB7BY (along with encouragement and help from Mike WA6SVT and area ATVers) installed the Las Vegas ATV repeater at the 8500-foot level of Mt. Potosi (just west of Las Vegas). The output is on 1253.25 MHz with a primary input on 434 MHz (AM-TV) and an alternate input on 913.25 MHz (FM-TV).

From his mountaintop home at Crestline, California, Mike WA6SVT could access the Mt. Potosi machine quite regularly, even though it was 200 miles away! Linking Las Vegas with the Los Angeles area looked like a possibility. Since a direct hop was quite weak most of the time, an intermediate relay site was needed.

Rodman Mountain turned out to be the ideal site for the relay. Even through it's located 48 miles from the WB6VVV machine at Crestline, and over 110 miles from KB7BY/r at Mt. Potosi, the reception at Rodman was good from both repeaters.

The Rodman Relay

The Rodman relay site is rather unique. With two receivers and two transmitters, it operates as a full-duplex dual-direction link. To relay video from Mt. Potosi down to California, the Rodman site has a 1253.25 MHz receiver which constantly monitors the output of the KB7BY repeater. This is relayed back to Job's Peak machine via a directional 1289.25 MHz FM-TV transmission.

To send video back to Mt. Potosi from the Job's Peak repeater in California, the Rodman site monitors a 33cm link and relays it to Mt. Potosi via another 1289.25 MHz FM-TV transmitter. To receive the Rodman relay, FM ATV receivers are located at both Job's Peak and Mt. Potosi.

Since the Rodman transmit antennas are pointed in different directions, the capture effect of FM-TV allows the use of the same frequency (1289.25 MHz) in both directions!

Priorities and Control

OK, sounds good, but how do you activate the link? You don't; it operates automatically. The link video is always available at the repeaters on each end of the path. All the repeater controllers at Mt. Potosi and Job's Peak do is choose which video signal to repeat.

This is done with a custom repeater controller that is installed in each ATN repeater. Here's how it works: The controller monitors up to eight sources of video. These can be from the demodulated output of different input frequencies, the Rodman link, a video ID, or even a local feed (such a satellite dish tuned to NASA Select). The controller prioritizes each video input port. If just one video source is active, then it gets repeated out. If two or more signals are active at the same time, the controller sends out the video with the highest priority.

For example, you can set up 434 MHz as your primary input, 913.25 MHz as the secondary, the link next, and finally a computer video ID. As soon as any local activity stops, anything coming in from the link receiver comes on line. When all activity stops, your repeater ID comes up. You can even set it up so that a control operator can redefine the priorities via a remote command. This would be useful if you want the link to be the primary signal for special nets.

Most ATN repeaters have another interesting feature. Whenever something comes in on a link frequency while local stations are using their repeater, the link signal is inserted into the local picture as a "picture-in-picture". Although this feature can be turned off, you never have to miss what's going on in the rest of the system.

The current system has the potential to allow ATVers over 400 miles apart to work each other. For those of you who live in the flatlands, this is definitely what you would call a significant band opening!

Photo B. Bill KB6MCU tests the WA6SVT ATV repeater on top of 5670-foot Santiago Peak.

Photo C. Geoff KB7BY adjusts the 23cm antenna which helps link the Mt. Potosi, Nevada ATV repeater into Los Angeles.

Linking up the Southwest

Future links are being planned as more and more mountaintop ATV repeaters sprout up across the Southwestern U.S. Some of you may be familiar with the linked systems of voice repeaters such as the ZIA connection, Cactus and the Condor system. Using a combination of these systems, I've been able to talk from El Paso, Texas to Santa Barbara, California (over a thousand-mile distance) from my 2m mobile rig to a friend on the beach on his HT! Believe me, it's quite fun to hear dozens of quick kerchunks as the stacked up repeaters drop out.

Using a series of 900 MHz, 1.2 and 2.4 GHz FM-TV links, a number of ATN machines will be linked up in the near future (see the figure for a map of all known ATV repeaters in the Southern California region). Work is currently underway to link from Los Angeles up to the N6VLV/WA6SVT repeater in the Tehachapi range east of Bakersfield.

There may even be a future link on up to the WA6YLB Blue Ridge repeater

Photo A. Some of the members of the Amateur Television Network (ATN).

east of Fresno. Just one more hop could take them all the way up to Sacramento and the San Francisco Bay area. To the west, Rod WB9KMO will be linking in from his Gibraltar Peak machine (as well as the K6TZ Santa Cruz Island link) above Santa Barbara.

To cover the area north of the San Fernando Valley, Dave WA6ZVE plans to link with ATN from his Loop Canyon machine. And to complete coverage in the Mojave Desert, Mark WB7AJC has his machine on top of 8400' Frost Peak near Wrightwood. Also in the future, there is interest from ATVers in Phoenix, Arizona (the AAA5 group), and some in Utah, in linking into the ATN system via Mt. Potosi.

ATN Activities

Lest you think that this might be too much for the ATN group, they are very experienced at bouncing video around via multiple links and repeaters. For many years, they've covered the annual Tournament of Roses Parade in Pasadena. Some of you may have seen the massive effort they put on during the 100th anniversary of the parade. They had 17 portable transmit sites along the parade route (14 fixed and 2 motorcycle mobiles, as well as W6ORG in his helicopter).

All the sites were linked back to mission control from a rooftop repeater, along with two separate 10 GHz links to tournament control and the public safety center. Not only that, thanks to Dave WA6ZVE, they linked it all up to a commercial satellite so that the whole country could watch the fun (they even arranged an intro about amateur TV by Michael Landon). Other activities that have been covered by the group include the L.A. Marathon, the Angeles Crest 100 race, and several boat races.

To aid in disaster assessment, they have installed ATV antennas in several of the sheriff's department helicopters. In addition, a number of EOC centers have ATV receivers which are tuned into the ATN network. In the event of an emergency, ATN members (in support of RACES) can transmit video from the helicopters which can be viewed at the emegency control centers.

There's plenty to watch on the ATV repeaters in Southern California. They even occassionally link a remote observatory so that astronomy buffs in the greater L.A. region can watch the heavens from clear skies.

You Haven't Seen Anything Yet

If you're in the L.A. area or just visiting, give the locals a listen on their calling frequency of 146.43 MHz. The weekly ATN net meets every Tuesday evening at 8 p.m. They have 2 meter remote bases at each ATV repeater site which allows check-ins from a wide area. This includes ATVers in the Las Vegas area who can not only watch the action, but check in on voice as well using the Rodman link.

If you'd like to find out more about ATN, and help out with future link possibilities, you can contact them at the following address: ATN c/o Mike Collis WA6SVT, P.O. Box 1594, Crestline CA 92325.

More Machines

There are a number of ATV repeaters which are not connected into the system. The K6KMN repeater (434 in/1241.25 out) sits on top of Mt. Wilson above Pasadena. From its vantage point with wide coverage of the L.A. region, this is a good place to look during shuttle missions for live video from NASA. Listen for the Mt. Wilson net on 146.43 every Monday night at 8 p.m.

The Sulphur Mountain group has the WA6UCL (1253.25 out) repeater, which covers Simi Valley and the Ventura area. They have a net every Tuesday night on the 146.88 repeater at 8:30 p.m. In the San Diego area, watch for the WA6VLF repeater (1277.25 out) on top of San Miguel mountain. For those of you north of Santa Barbara, look for the Buellton repeater (K3NXF) in the Santa Ynez valley.

As more and more repeaters spring up across the Southwest, it won't be too long before an ATVer in El Paso or Salt Lake City can link up to watch the sunset over Catalina Island! 73

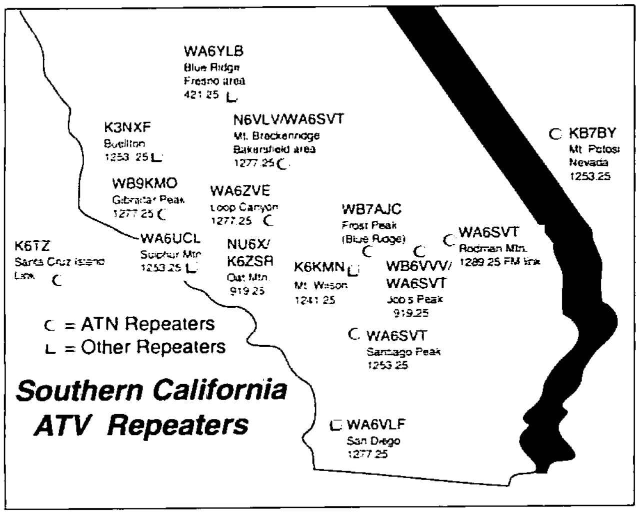

Figure. ATV repeater locations in the Southern California region.

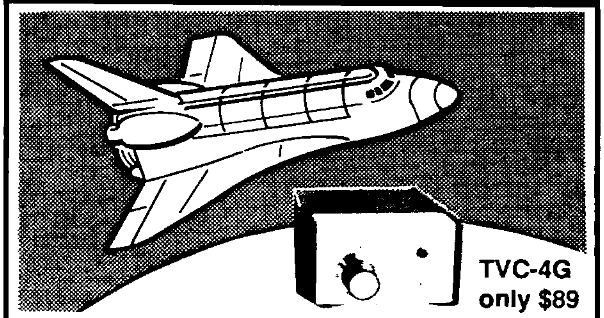
AMATEUR TELEVISION



SEE THE SPACE SHUTTLE VIDEO

Many ATV repeaters and individuals are retransmitting Space Shuttle Video & Audio from their TVRO's tuned to Satcom F2-R transponder 13. Others may be retransmitting weather radar during significant storms. If it is being done in your area on 70 CM - check page 413 in the 91-92 ARRL Repeater Directory or call us, ATV repeaters are springing up all over - all you need is one of the TVC-4G ATV 420-450 MHz downconveters, add any TV set to ch 2, 3 or 4 and a 70 CM antenna. We also have downconverters and antennas for the 900 and 1200 MHz amateur bands. In fact we are your one stop for all your ATV needs and info. Hams, call for our complete ATV catalog - antennas, transceivers, amplifiers. We ship most items within 24 hours after you call.

Professional Tool Case

SPECIAL
$59.95
Reg. ~~$80.00~~

Makes a Great Holiday Gift!

Model ZIM5

- Two removable pallets hold over 60 tools
- Case top has built-in document holder
- Case bottom is partitioned into 3 areas

A handsome black case to organize and transport your valuable tools and instruments. This is the same quality case used by literally thousands of professional field engineers. Case is made of high impact polypropylene, and has snap-action key locks and a padded handle.
Size: 17½" × 12½" × 5".
Tools are not included.
Offer expires December 31, 1991.

To order call:
1-800-225-5370
In MA: (508) 682-2000
Same Day Shipment!
Money Back Guarantee!
Terms: Visa, MC, Amex:
P.O.'s from qualified firms accepted.
Add $6.75 for packing and delivery.

HOMING IN

Radio Direction Finding

Joe Moell, P.E., KØOV
P.O. Box 2508
Fullerton CA 92633

RDF Potpourri

More and more ham clubs are discovering the fun of hidden transmitter hunts, often called "foxhunts" or "T-hunts." To get your group started, all you need is someone to hide the transmitter, and some sort of audio/control unit for the transmitter. Last month's "Homing In" column featured construction plans for TBOX, an easy-to-build tone/ID generator and on/off cycler for hidden T's.

As I indicated last time, TBOX inventor Ron Seese N6MBR has a PC board available. The board layout includes some optional "bells and whistles" that were not part of last month's simple 6-IC project.

By adding a Dallas Semiconductor DS1216C SmartWatch RAM socket and a few other parts to the board, you can program TBOX to start transmitting at any selected day and time. That's perfect for advanced hunts with multiple transmitters.

If you are not going to stay close to your hidden T, you need a way to turn it off remotely, to satisfy FCC 97.109. Ron's board has provisions for an SSI-202 DTMF decoder IC to control it via a link receiver above 222 MHz (FCC 97.201(b)). A 144/222 or 144/440 MHz dual-band rig is perfect for a remotely-controlled 2 meter fox with TBOX.

TBOX's user-friendly firmware is easy to use (Photo A). Ron continues to develop new versions to incorporate these optional features. To find out what's available, send an SASE to him at 6136 Landino Drive, Westlake Village CA 91362.

TBOX Construction Hints

You can use non-CMOS parts at U1 and U2, but power drain will increase significantly and regulator U7 will run much warmer. Bolt a heat sink to U7 if you use non-CMOS parts, or if your TBOX must operate in a hot location.

Dallas Semiconductor's DS1228 RS-232 interface IC is a direct replacement for the Maxim MAX232 at U6. Advanced Computer Products has the DS1228 and all other ICs except U5, plus the crystal. ACP is located at 1310 East Edinger Avenue, Santa Ana CA 92705; telephone (800) 366-3227. U5 is available from N6MBR.

Most mobile and hand-held rigs on the market today require less than one milliamperes to key the PTT circuit. Older transmitters such as the TS-700A use relays that draw more current than Q1 and U1 can supply. If in doubt, use a multimeter to measure the current in your rig's PTT line when you key down.

If PTT current is more than 10 mA, add a reed relay, such as Radio Shack 275-233. Connect the coil between +12V and the collector of Q1. Connect the relay contacts to your rig's PTT circuit. To protect Q1 from voltage spikes from the relay coil, put a 1N4001 diode (RS 276-1101) across the coil. Cathode of the diode goes to the +12V side.

T-Hunting in the Desert

Hams in Phoenix know how to promote their hobby. For example, everyone there knows about the thousands of phone patches that were put through K7UGA's super-station over the years by dozens of dedicated volunteers.

Now another voice is bringing ham radio to the citizens of that area. Len Winkler KB7LPW (Photo B) hosts "Ham Radio and More," a one-hour program devoted to all aspects of our hobby. It airs weekly on KFNN, a 10 kilowatt radio station at 1510 on the AM dial, covering much of central Arizona.

Some talk radio jocks have it easy. They gab for two minutes and then play five minutes of commercials and traffic reports. (Seems like it, anyway.) Not Len. When he opens his mike at 2 p.m. each Sunday, it stays open for the full hour. Sure, there are a few commercials (very few), but they are personally voiced by Len, live.

Len knows that most of his listeners aren't hams—yet. So he doesn't spend his hour wailing about insider topics like spectrum preservation and packet business message citations. Instead, he seeks out guests who can excite his listeners by telling about the many fascinating aspects of life as a ham.

I had the privilege of being on Len's show recently. It was easy to talk with him about competitive radio direction finding because he had already been T-hunting with John Moore NJ7E. John joined us on the air to offer a challenge from Arizona RDFers to the T-hunters of Southern California.

John wanted to see how my Southern California friends and I would fare on an Arizona-style hunt during the October ARRL convention in Scottsdale. The two areas have very different philosophies about T-hunting.

So-Cal hunters love long drives and they don't mind very weak signals. Almost everyone uses a rotatable beam or quad, and many have GaAsFET preamp SSB detectors to make the most of fractional microwatt signals that could be very far away or very well concealed. The T is often 200 miles or more from the start point on day-long or all-weekend hunts.

On the other hand, Arizona hunters value speed and strategy. Though all kinds of RDF gear are seen, Doppler sets with four or eight whip antennas are most common. Fox signals are strong and distances are moderate. Hunters try to drive to the fox as quickly as possible so the post-hunt social activities can begin.

It looks like some interesting interstate competition could be coming up. Stay tuned for more.

First So-Cal R-Hunt

Suppose your club wants to try foxhunting, but only one member has any direction finding equipment. How do you put on an event to demonstrate RDF and make it possible for anyone with a mobile rig to participate? The answer: A hidden receiver hunt.

As Robin Rumbolt WA4TEM described it in *73 Amateur Radio Today* (July 1990, page 12), the fox in a hidden receiver hunt is the only one who has an RDF set. He or she listens to transmissions from the hunters and gives them bearings relative to the hidden location. Hunters add or subtract 180 degrees to or from the true fox-to-hunter bearing to get a hunter-to-fox bearing, which they plot and follow.

The Los Angeles Disaster Communications Service held an R-hunt on 27 July as a way of introducing DCS members to the fun and usefulness of RDF. The boundaries encompassed 420 square miles of central Los Angeles county.

The hunt took place on the 145.30 MHz RACES repeater. Dennis Soja KB6NJF and Dean Coulter NØCGW hid their receiver/quad RDF setup on the famous Mulholland Drive north of Hollywood. Some the bearings were inaccurate because of the intervening hills, but eventually all the competitors found them.

The first R-hunt was successful in attracting hams who had never tried RDF because they lacked the gear for it. I'm sure we'll soon see these folks on some of the 15 regular monthly Southern California T-hunts.

T-Hunters Aid FCC Bust

Just in from the city by the bay: Ham RDFers have helped the FCC nab an Advanced Class ham who allegedly had been using a modified dual-band transceiver to cross-link up to 18 law enforcement agencies. Public service dispatchers found themselves talking to units in other jurisdictions during the cross-linking. The suspect is also accused of jamming ham repeaters and cross-linking ham transmissions onto public safety frequencies.

Formal charges have not been filed as of this writing, so the assisting hams aren't talking about how they aided the FCC. All we know is that the suspect was apprehended while mobile along Highway 101 on the peninsula south of San Francisco. As this case is resolved, I hope the T-hunters will be able to share the story of their success with us.

R.I.P. PELTS

At deadline time, the FCC announced the termination of PR Docket 89-599, thus abandoning plans for a Personal Emergency Locator Transmitter System. What does this mean to hams and others interested in RDF for search and rescue? Will there soon be a crackdown on the illegal use of aircraft Emergency Locator Transmitters as personal rescue beacons? Or might this unorthodox ELT use become legalized?

RDF for wilderness safety is a topic that always generates a lot of reader interest. Look for an analysis of the current situation in an upcoming "Homing In" column. Meanwhile, I welcome your comments on the subject, or on any other RDF topic. 73

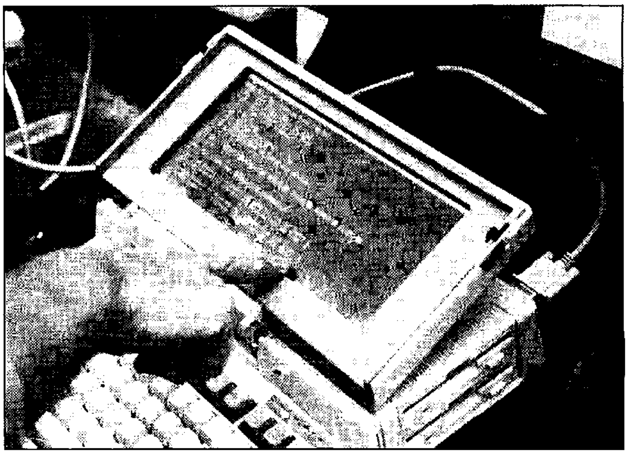

Photo A. TBOX parameters can be changed in the field with a laptop computer operating in the "dumb terminal" mode. The firmware is menu-driven.

Photo B. Len Winkler KB7LPW regaled listeners with T-hunt talk on his "Ham Radio and More" show recently.

Voice ID *Continued from page 12*

your signal is distorted, you'll have to adjust R11 to reduce the audio signal to the proper level. This is typically about 20 millivolts or so.

Repeater/Beacon/Foxhunt Voice ID

You can use the voice ID for a repeater identifier. Just hook a logic signal from a repeater controller or a timer circuit in place of switches S1 and S2. Whenever the incoming logic signal goes low, one of the messages will be played.

This would also make an excellent hidden transmitter identifier for foxhunting. Just record a tantalizing message like, "Catch me if you can!" and watch the fun and frustration as your friends try to locate the transmitter. You could even program in two messages and have them alternate. If you short out either switch S1 or S2, the voice ID circuit will play back in a continuous loop through the whole 16 seconds (if you close S1), or eight seconds (if you short out S2).

If you add the dimension of voice to a beacon transmitter, you can take advantage of the digital control power of the ISD1016 chip and sequence through multiple messages. I plan to use one in upcoming helium balloon experiments where I send up 2m FM transmitters to 100,000 feet. With a few additions to the basic voice ID circuit, the sky is definitely the limit! 73

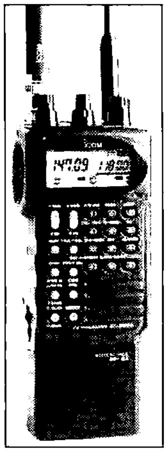
NEW PRODUCTS

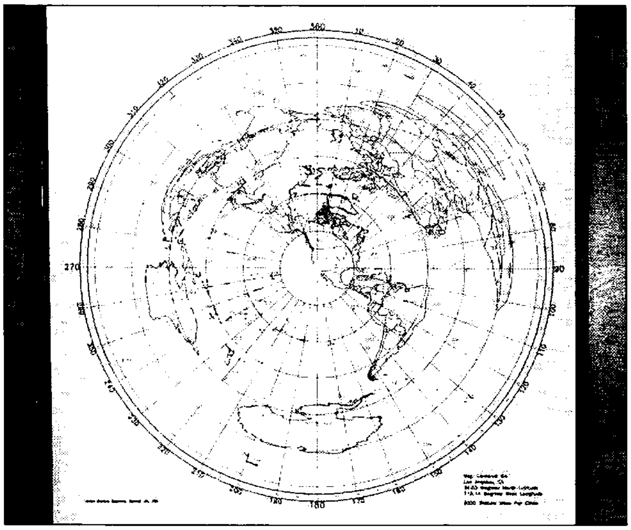
Compiled by Hope Currier



ICOM

Icom has introduced the IC-2SRA 144 MHz and IC-4SRA 440 MHz hand-held transceivers, with a wideband receiver installed directly into the unit. These compact HTs (13.6 ounces; 2.1" x 5.3" x 1.4") will receive everything from 25 to 905 MHz. If you connect an external 13.5 volt power supply, these handhelds will provide a full 5 watts of output power. Independent squelch and volume controls allow you to change settings in each band separately. Icom's frequency monitoring system lets you monitor memory channels, the complete frequency band, specific parts of the band and priority channels. There is a built-in pager and code squelch unit. The IC-2SRA and 4SRA also have 96 memory channels, a 24-hour clock, four DTMF memory channels, and a variety of tuning steps.

The suggested retail price for each model is $599. For more information, contact *Icom America, Inc., 2380 116th Ave. N.E., Bellevue WA 98004; (206) 454-8155, FAX: (206) 454-1509.* Or circle Reader Service Number 201.



VECTOR CONTROL SYSTEMS

Vector Control Systems has released a new 16" x 16" x 1" electronic beam indicator. Using a four-color custom-plotted great circle map (centered on your QTH), the indicator shows your antenna's direction and coverage with a 5 degree resolution. A simple connection to any standard rotator control unit makes the beam indicator operational. The adjustable beam width indication is a special feature which allows you to match it to your beam's radiation pattern.

The indicator is available in a glass-covered black or silver frame. It's priced at $179.95, plus $8 S & H. Contact *Vector Control Systems, 1655 North Mountain Ave., Suite 104-45, Upland CA 91786; (714) 985-6250.* Or circle Reader Service No. 204.

WINTER DESIGN

Winter Design is offering a unique gift for the office or home for engineers, technicians, hams or computer fans: a clock made from an actual etched printed circuit board. This battery-operated clock is 17" x 17", and comes in two color combinations: blue board/silver etch/silver frame/white silk screen hands and numbers; or green board/silver etch/silver frame/white silk screen hands and numbers. The price is $49.95, plus $5 S & H. Contact *Winter Design, 267 Court Rd., Winthrop MA 02152; (617) 846-5745.* Or circle Reader Service no. 207.

TRIPP LITE

The new Tripp Lite PR-Series DC power supplies are housed in a compact, dark metal cabinet that blends in with modern communications and amateur radio equipment, giving an integrated, professional appearance to any radio or electronics installation. The PR-Series gives exceptional performance for base or mobile radios, test equipment and other electronic gear. Its continuous-duty performance stands up to extended periods of operation for reliable operation under all circumstances. These DC power supplies offer crowbar protection, excellent IC voltage regulation, automatic overcurrent protection and full-line isolation, providing clean, stable DC power for your equipment.

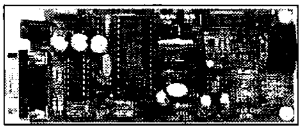
The PR-Series DC power supplies are available in 3 to 60 amp sizes, with suggested retail prices starting at $32. For more information, contact *Tripp Lite, 500 N. Orleans, Chicago IL 60610-4188; (312) 329-1777, FAX: (312) 644-6505.* Or circle Reader Service No. 203.

CONNECT SYSTEMS

Connect Systems is now offering a new low cost full duplex interconnect, the Model CS-800, which can be user-programmed to operate either full or half duplex. The Model CS-800 features a built-in repeater maker, a nine-number memory speed dialer, last number redial, a built-in user programming keyboard and digital display readout, user-programmable Morse ID, hookflash, ringout (sounds like a phone ringing), line-in-use detect/call waiting, regenerated tone or pulse dialout, programmable toll restrict, programmable connect/disconnect and secret toll override codes, programmable activity/timeout timers, non-volatile memory, and lightning protection.

The suggested retail price for Model CS-800 is $349. Contact *Connect Systems Inc., 2064 Eastman Ave., Suite 113, Ventura CA 93003; (805) 642-7184, FAX: (805) 642-7271.*. Or circle Reader Service No. 202.

A & A ENGINEERING



BayCom from A & A Engineering is a software-based packet system for PC/clones that does not require an expensive TNC. The modem plugs directly into a standard 9-pin serial port, or a 25-pin port with an optional cable adapter. A 45-second watchdog timer and reed relay PTT are standard. A small wall-power supply and a software disk are included with each kit or assembly.

No alignment is required for either HF or VHF operation. A single three-position mode switch allows HF, VHF normal or VHF with equalizer operation. The modem circuit provides improved HF receive operation.

The price for a blank board, #190-PCB, is $12.95; a complete kit, #190-KIT, is $59.95; an assembled and tested board, #190-ASY, is $89.95. U.S. Shipping is $5. California residents add 7.75% sales tax. Contact *A & A Engineering, 2521 W. LaPalma #K, Anaheim CA 92801; (714) 952-2114, FAX: (714) 952-3280.* Or circle Reader Service No. 205.

CW ENTHUSIASTS

CW Enthusiasts has released PC Super Keyer 2.1. This software for IBM compatibles provides all of the features of expensive memory and keypad keyers in an economical and easy-to-use package. It features paddle or keyboard input, disk storage space for eight unlimited-length messages, transmission of any text file, beacon operation, message within message, on-screen display of paddle input and local/UTC clocks. In addition to functioning as a keyer, PC Super Keyer will send random five-letter code groups of random or U.S. callsigns for code receive practice. The on-screen translation and display of paddle input can also be used to practice sending with a paddle.

The PC Super Keyer is priced at $24.95 for software and complete documentation, $39.95 with an interface parts kit, and $49.95 with the assembled and tested interface, plus $3 S & H. It is available on 5.25" and 3.5" disks. Contact *CW Enthusiasts, 1346 Erickson, Suite R, Columbus OH 43227-2061.* Or circle Reader Service No. 206.

Holiday Gifts

The holidays they are a'coming! Next month begins with Chanukah, then Christmas and Kwansa. Whatever your orientation, it seems appropriate to look into gift giving this month. Let me take this opportunity to highlight items of interest to digitally-inclined amateurs.

No doubt about it, gift giving can get expensive. With amateur radio, it can get *very* expensive! But not all of us are independently wealthy, and often the pleasure inherent in a gift has nothing to do with its cost. To that end, I shall try to break down my suggestions into categories, by cost. To use this column effectively, either circle or highlight items of interest to you, or place a sticky note with an arrow on the page, leaving the magazine open on the kitchen table. A flashing red light or rotating beacon might be a bit too much, though.

Very Low Cost or Essentially Free

A piece of newsprint in a frame graces one wall of my shack. Crayoned thereon is my toddler's impression of daddy on the radio. Cost? Nil. Meaning? Unmeasurable!

Is someone in the family handy with needle and thread? How about a dust cover for the equipment, as opposed to the commercial plastic jobs? A cushion for the operating chair might be nice as well.

You get the idea? Handcrafts of any sort can be applied to the ham/computer shack in an endless variety of forms. From a ceramic holder for this or that, to a custom-made hat (bought cheaply at the variety store and hand-decorated), it doesn't have to cost a lot to be meaningful.

Under Ten Bucks

For the RTTYer who is using a mechanical teleprinter, a trip to the office supply store will turn up many useful items, which are quite affordable on a harmonic's budget. Standard Underwood typewriter ribbons fit Model 15/19 teleprinters. Various types of cleaning putty and paper products are also available to keep the print sharp and readable. A tube of Lithium grease from the hardware store can also help with machine maintenance.

Other items useful in the ham shack include a supply of solder, test clips, connectors, or other small items of use to home-brewers. Is there a local amateur supply store in your area? See if they will provide a gift certificate, to allow the ham to select his or her own goodies.

Computer-oriented hams seem to always be able to use floppy disks (be sure to get the right size) and paper for the printer. There are a variety of novelty items, ranging from special pens with which to label disks, to boxes to put those disks in, all quite nominal in price.

Software is always in fashion, as well. For the best value for the dollar, it is hard to beat the collection offered by this column. PC compatible users can obtain the latest TRTY (teletype) program, on disk, for a self-addressed stamped disk mailer and $2.00. I have been known to fill space on high density (1.2 and 1.44 Mb) disks with extra programs, as well. Send requests to the above address.

Commercial sources include Aero Data Systems, a *73* advertiser who offers a wide variety of programs for PC clones, Amiga, and C-64 systems. Priced at $4.50 per disk, this is a good way to obtain some fine public domain and shareware offerings.

Reasonably Priced

I know, what's "reasonable"? My intent here is to look at stuff which is under a hundred dollars, and which represents good value for the dollar. So, while price is not the only objective, I will use it as a yardstick.

How about a good book? Our dear old Uncle Wayne has a Bookshelf just loaded with sources you will want. Here's a partial list.

- 07R25, *The RTTY Listener*: Up-to-date, hard-to-find information on advanced RTTY and FAX monitoring techniques and frequencies. $19.95
- 03S208, *Radioteletype Press Broadcasts*: Press service schedules in English, French, German, Spanish and Portuguese. $12.95
- 03R01, *World Press Services Frequencies (RTTY)*: 5th edition manual with all information, plus coverage of 65 World Press Services broadcasting In English. $8.95
- 03R02, *RTTY Today*: Covers all facets of RTTY, fully illustrated. $8.50
- 01P22, *The Packet Radio Handbook*: The definitive guide to amateur packet operation. $14.50

Users of the AEA line of multimode controllers often express a desire for more powerful controller software. PktGOLD is advertised as one such program. It should greatly expand the capabilities of the PK-232 and PK-88 controllers. The program is available for $59.95 plus $5 shipping and handling from InterFlex Systems Design Corporation.

Do you have a CD-ROM drive on your computer? Buckmaster Publishing has the HamCall CD-ROM, which has listings on 500,000 amateurs, plus "1000's of public domain amateur radio programs and data." The disk itself is only $50, cheaper than a stack of *Callbooks*! Contact Buckmaster for full details.

More Than A C Note

Now, there will be situations and circumstances where someone might be willing to spend some real money on you. Other than the obvious items, a new computer, printer, or radio gear, let's take a look at some specific material of particular use to the RTTYer.

In most RTTY shacks, there is never enough test equipment. Frequency counters seem invaluable for a mode so locked into certain frequencies. Startek International has a 1500 MHz hand-held counter with accessories for $128, which should find a place on any amateur's bench.

We've covered WEFAX here before, so take a look at Software Systems Consulting's PC GOES/WEFAX 3.0, for $250. This is a professional FAX reception system for PC clones. Including an AM/FM demodulator, software, and tutorial, this looks like one capable system. For a bit less money, their PC HF Facsimile 5.0 is an HF FAX system, also including an FSK demodulator. This one is available for S99. They tell me that if you get PC HF FAX, you can add PC SWL for another $20. This is a demodulator, software, and manuals to get you onto listening to Morse, RTTY, and other modes on the HF spectrum. Overall, these sound like very interesting packages.

MFJ is now offering their MFJ-1278, a multimode controller that features packet, AMTOR, RTTY, ASCII, CW, FAX, SSTV, and more, with color SSTV supported with appropriate software. At $279.95 for the base unit, this one will be hard to beat! I wouldn't mind getting one of these, myself!

AEA has updated the venerable PK-232MBX with new software, reportedly making it a strong contender on the air. Their new DSP-2232 looks very good on paper, and I look forward to reviewing it as soon as information becomes available.

So, What'cha Gonna Do?

I hope I have been able to plant a seed or two that might germinate into something wonderful this holiday season. As we gather together to observe our various customs, let us reflect upon the wonder of amateur radio. This hobby of ours is unique in that it breaks down boundaries, bridges languages, and allows cultures to communicate. Through communication comes understanding. Through understanding comes friendship. Through friendship comes peace. May this be a season of peace and understanding for all of us, our families, friends, neighbors, and governments.

I look forward to hearing from you by mail, or by e-mail on CompuServe (ppn 75036,2501) or Delphi (username MARCWA3AJR). As I write this, I am looking at another on-line service as well. Perhaps I'll write more on that one down the road, along with other goodies here on RTTY Loop. 73

ABOVE AND BEYOND

VHF and Above Operation

C.L. Houghton WB6IGP
San Diego Microwave Group
6345 Badger Lake Ave
San Diego CA 92119

Microwave PLL Brick Filters

The basic filter covered last month was the most inexpensive filter available—a tin can and a variable capacitor. This month I'll continue to cover filters and their applications as they pertain to microwave oscillator (brick) filters, in particular the modification for operation on the amateur band. This modification requires re-tuning the filter about 1 GHz lower in frequency.

The moditication of the phase-locked oscillator's filter can involve a little bit of black magic, which I hope to unmask. It's easy to modify brick filters if you have a spectrum analyzer handy, but you can also adjust them to the desired frequency with a power meter. However, you can never be quite sure that it is providing proper harmonic output when completed.

Power and Crystal Oscillators

Surplus brick oscillators were originally constructed for the commercial common carrier frequency bands 5.9–6.8 GHz and 10.7–12.7 GHz. These frequency bricks are of prime interest to amateurs for both the 6 and 10 GHz bands. The bandwidth of the original filler varies from 300 to 500 MHz at the 3 dB points. Whatever frequency brick you select, it must be electrically and mechanically sound.

The brick oscillator has a high power oscillator operating in the 1.2–2 GHz range with about 1/4 watt power output. This oscillator is compared to a crystal in the 90 to 108 MHz range and is phase-locked by a varactor control circuit to lock the high power oscillator to a harmonic of the crystal oscillator. This harmonic number is normally the 12th in a 6 GHz brick, and uses the 17th or 18th harmonic in a 10 GHz brick.

This power oscillator is adjustable with a cavity tuning screw to obtain phase-lock in reference to the crystal oscillator. The output from the power oscillator is then coupled to a step-recovery diode frequency multiplier, and the selected harmonic is passed by the output microwave filter. This is all part of the multiplier assembly, which is the top rectangular module under the blue label, as shown in Photo A.

The filter's job on this assembly is to attenuate all unwanted harmonics. The output of the SRD multiplier is rich in harmonics. The filter can be hundreds of MHz wide and still be effective. In a 10 GHz brick, it can reject the 16th and 18th harmonic and pass the 17th harmonic. Most bricks that you find will cover a wide variation in frequency, but electrically they are the same. The big difference is where the filter is tuned, and for very high frequency operation some cavity dimensions are shorter. This makes modifying a 12.5 GHz brick a little harder than an 11.5 GHz brick.

Let's get into the modification details. I will modify a Frequency West brick. Though the principles of modification are also applicable to the California Microwave bricks, they require slightly different construction methods. Two different types of filters are used, and I will cover them both.

The Frequency West Brick

The 10 GHz Frequency West brick I converted was originally set for operation between 10.750 GHz–11.750 GHz. I re-tuned it to 10223 MHz in the 10 GHz amateur band. In a 6 GHz brick the filter is re-tuned to 5.615 GHz, assuming you are using a 145 MHz multimode radio for the variable IF. This produces 10.368 GHz and 5.760 GHz, which is the upper mix products using a 2 meter transceiver for our IF.

The Frequency West PLL brick high power oscillator is pre-set to the low end of the filter passband, as evidenced by reduced output power. Adjust the filter slightly to increase power, repeating this procedure several times until the filter frequency is within the target frequency of 10.223 GHz.

In difficult cases, with the filter mistuned and no output signal, you have a problem. Real black magic is now at hand. Go slow and do not tune the filter in large steps. Remember which element (last adjusted) caused trouble, and return it to its prior setting before adjusting another element of the filter. When out of wack, it's quite hard to set up without good test equipment.

The brick will give a swept output when operating without a crystal. It is being swept by an internal housekeeping circuit used to obtain phase-lock whenever power is turned off and on. This sweep circuit is disabled automatically when the low frequency crystal is functioning.

Modification Details

Begin the modification by removing the blue label on top of the unit, pealing it back slowly. This reveals four large screws recessed on the corners of the unit. Unscrewing the panel allows you to remove the multiplier assembly (required on some units). However, if your unit has a set of five Allen set screws held in place with lock nuts, you do not need to remove the multiplier to make the adjustments. But if your unit has only the Allen screws, you *will* need to remove the multiplier.

To unmount the multiplier, remove the four 6/32 bolts, lift the module up, and swing it around 180 degrees. After you complete the modification of the oscillator, reinstall the multiplier by reversing these directions. Then place the coupling probe back into the cavity port and hold it in place with a mounting screw, clamp, or several rubber bands.

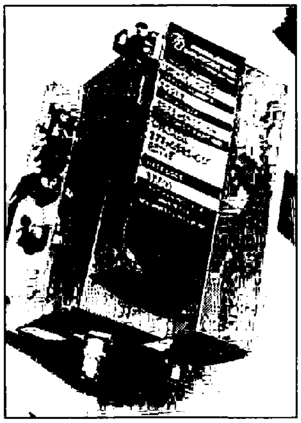

Photo A. The Frequency West 6 GHz PLL brick. It's mechanically similar to the 10 GHz brick. Remove the blue label on top to access the filter adjust screws.

When the unit is in this position you have access to the real tuning screws. (Note: Some units have an access plate on the back portion of the module which you must remove to give clearance to the inside Allen filter screws). The screws on top are lock screws (Allen head 0.035 inch), and the Allen screws on the inside of the multiplier assembly, just under the lock screws, are the filler adjusting screws.

Movement of the filter screws is not radical, and filter alignment will be facilitated with less than one turn of the set screw. Go slow. Unlock the locking screws first, and only then, when you are ready to observe power or output on a spectrum analyzer, make filler adjustments. I have not worried about passband results, just peak power output at the frequency of interest.

Once the proper frequency is reached, you can insert the crystal into the circuit and attempt phase-lock. The crystal is adjusted by turning a small variable capacitor while watching the "XTAL" lead on the side of the brick for DC voltage output. A voltage of about 0.5 VDC indicates that the crystal is oscillating. Adjust the cavity tuning screw while watching the "0" or phase-lock terminal. Normally, out-of-lock is a steady negative 10–13 volts. This voltage will jump to a value of between 2–13 volts. When in-lock, this voltage will follow small adjustments of the cavity tuning screw.

When phase-lock is obtained, you should be near the exact microwave frequency desired. Slight adjustment of the low frequency oscillator circuit will obtain the desired results. This, of course, depends on the crystal being set to exactly the proper frequency. For example, in my brick I wanted a final frequency of 10.223 GHz (10223 MHz). This required a crystal of 100.2254902 MHz, the 102th harmonic of which is exactly 10.223 GHz. Close enough for government work.

Now, with phase-lock and proper frequency output, you can do a final adjustment on the filter for peak output, then lock the adjustments down. I usually obtain +7 to +10 dBm power output, plenty of power for a mixer at 10 GHz. Final adjustments take time, as you might have to jiggle both the filter

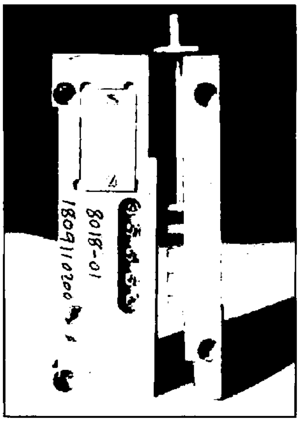

Photo B. The 10 GHz filter assembly. Note the 5-pole filter elements. The last element is connected to coax with an SMA output connector. When the filter is assembled, the five elements are next to and under the lock nuts of the five screws on top of the filter body. The filter elements are inside the filter body. Screws and lock nuts are under the blue factory label, and the four mounting holes are on the filter's edges.

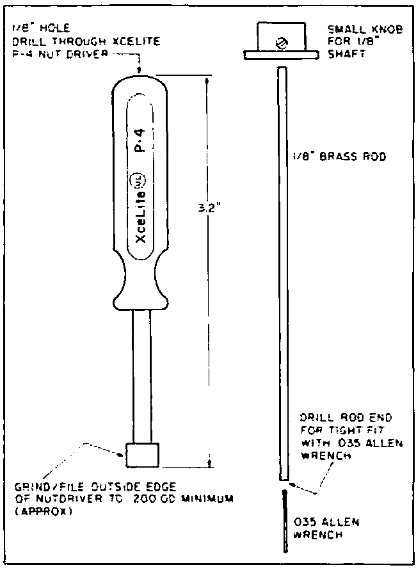

Figure. You can modify a nut driver to construct a tool for brick filter alignment.

and lock screws. There is some displacement of the adjustment screw when the lock screw is tightened, and both screws must be done together or all is for naught. Balance the lock screw's action with the adjust screw; it's a matter of feel, and you will see what I mean when you try it.

Adjustment Tool

It's difficult to adjust the screw and lock nut with an Allen wrench and a pair of pliers. To overcome this problem, I constructed a two-stage tool by modifying a standard nut driver that fits the lock nut. See the figure for details. The nut driver is modified by first drilling a hole about 1/8-inch in diameter through the length of the plastic handle so a solid brass rod can be inserted through the nut driver, handle and all. I used an Xcelite™ P-4 nut driver (0.129-inch hex head nut driver).

In turn, the brass rod is drilled on one end to accept the 0.035-inch Allen wrench. Brass is soft; under-drill the hole slightly, at about 0.032 inches, so the Allen wrench will fit tightly. The hole will expand slightly to accommodate it. On the other end, attach a small knob to the shaft. Use the nut driver to unlock the lock nut, and the Allen screw to adjust the filter element. While holding alignment steady, the lock nut is turned tighter. You will have to do this several times to obtain maximum output on each filter element.

The procedure is the same for those bricks with top locking screws and a side filter. In this model, you may have to use two Allen wrenches. On both filter assemblies there is a small potentiometer that should be left alone unless you have high output on 11 as well as 10 GHz. This is the bias adjust for the SRD multiplier diode. It's best adjusted while watching the oscillator on a spectrum analyzer for minimum high harmonic output.

And that's it. If you removed the multiplier assembly, reassemble it by rotating it 180 degrees and replacing the four screws that you originally removed. The probe into the RF compartment is self-centering.

A small rubber boot can be made to cover the crystal, forming an insulator for the oven assembly. You can construct one out of about an inch and a half of monkey rubber tape, which is available at most hardware stores. When stretched slightly, the tape will adhere to itself. I wrap it around the crystal heater and fold the excess on top of the crystal, making a little box affair to shield the crystal from draft and maintain temperature stability.

Brick Availability

These surplus brick oscillators are being removed from commercial telephone service. As more and more older systems are being replaced with digital and light guide facilities, surplus channels will acquire more and more of these oscillators and other high quality microwave components useful to the amateur microwave technician.

I have picked up a small quantity of the 10 GHz phase-locked brick oscillators, and will make them available for $50 postpaid in the U.S. If you want me to re-tune the output filter to 10.223 GHz, I will be glad to do so for an additional $15. It takes about a half hour to completely tune one up.

By the way, the crystal used in these oscillators is available from International Crystal Co. and costs about $20. Specify Frequency West part #585132 and the type of brick you have, such as Frequency West 54XOL output frequency 10.223 GHz.

Other articles in *73* have covered these brick oscillators. Check out June and July 1990 for temperature control and typical internal crystal oscillators. Full details with block diagrams covering a 5 GHz brick were in the September 1990 "Above & Beyond" column. For the 10 GHz brick system, see this column in the December 1989 issue.

That's it for this month. I'm getting ready for the 10 GHz ARRL contest and will update you on operations and any unusual happenings. As always I will answer questions concerning microwave and related topics. Please enclose an SASE for prompt reply.

HAM HELP

Your Bulletin Board

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full (8½" x 11") sheet of paper. You may also upload a listing as E-mail to Sysop to the 73 BBS /Hamhelp SIG. (2400 baud, 8 data bits, no parity, 1 stop bit. (603) 525–4438). Use upper- and lowercase letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters 1 or i, or even the number 7. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

Can anyone help a DXer to get some old-fashioned transmitter and modern-day shortwave sets? A Yaesu FRG-8800, any HW101 homebrew 21 MHz CW transmitter, and a 21 MHz shortwave, would do good for DXing. Thanks. *Mac Arthur Herman Moore KA3LLY, 5230 Heston St., Philadelphia PA 19131.*

Wanted: Schematic and/or manual for Eico Model 315 Signal Generator. Will pay copy and mailing costs. *Larry Keith KF8BX, 4251 Meadowsweet Dr., Dayton OH 45424. Telephone: (513) 233–1148.*

I need a schematic for a Regency HR2-A 2m FM radio for a new ham in my radio club. Please send reply to *Steve Lempke WA1MZL, 1538 N. Main St., Fall River MA 02720* or call *(508) 675–9923* after 5:30 PM EDT. Thanks.

Donations needed for an expedition: 6 meter SSB-CW rig, 100 W S.S. Amp & Beam, 2 m SSB-CW rig, 150 W output amp., 1 superlong yagi. Purpose is to give out new countries on 2 meter EME. Please send packages (marked "GIFT") to *PS7KM, Karl Mesquita Leite, Box 385, 59000, Natal, RN.* Thanks, from John WB8IGY of Cincinnati OH.

Wanted: Schematic and Manual for the Motorola U43HHT Low Band Rig, Receiver and Transmitter. Please mail to *9Y4VU, Franklin Brooker, 43 Seaview Dr., Battoo Lands, Mirabella, Trinidad.*

Wanted: August 1984 QST magazine or copy of the article entitled "Some Basics of VHF Design and Layout." Also, service manuals for Uniden HR-2600 and Heath HWS-2 HT. *Glenn KB5AYO, RT. 1 Box 580-B, Reserve LA 70084.*

Varian G-10 Chart Recorder. Need schematic and/or manual. I intend to solid-state it. Will pay copying and postage. *Brian WA5PPO, 6848 E. 45 St., Tucson AZ 85730-2214.*

HAMSATS

Amateur Radio Via Satellite

Andy MacAllister WA5ZIB
14714 Knightsway Drive
Houston TX 77083

Satellite Operation Today

A decade ago, few would have believed the day would come when there would be so many operational amateur radio satellites that one could be above a station's horizon almost continuously. Today we have 13. If you count the Russian space station *Mir*, with its 145.55 MHz packet BBS, we have 14. With multiple transponders on most of the spacecraft, satellite chasers have many options ranging from HF to microwave activity.

Although some might consider the HF transponders on RS-12 and RS-13 for relatively short-range contacts, others have found them to be a medium for worldwide communication. Using the Mode K transponder on RS-12 (uplink 21.210–21.250 MHz, downlink 29.410–29.450 MHz), over-the-horizon DX is possible when skip conditions permit it. A complete frequency chart for RS-12/13 is in the May 1991 "Hamsats."

For the UHF and microwave enthusiast, the Mode S transponder on AMSAT-OSCAR-13 (uplink 435.603–435.639 MHz, downlink 2400.711–2400.664 MHz) has provided many opportunities to work with 2.4 GHz equipment and make worldwide contacts via satellite.

Most satellite chasers prefer Mode A (2 meters up and 10 meters down) via RS-10/11 or Mode B (70cm up and 2 meters down) via A-O-13 or A-O-10. While RS-10/11 is in a low-earth orbit (several hundred miles high), A-O-13 and A-O-10 are in highly-elliptical orbits, traveling out past 20,000 miles at apogee, the orbit's farthest point from the earth. Even though the elliptical orbit satellites have gain antennas and high power transponders, ground stations will need quality antennas and expensive equipment for easy contacts. The RS-10/11 station is usually less complex, but the satellite's coverage is also less, due to the lower orbit.

Since the launch earlier this year of RS-14, also known as RADIO-M1, RUDAK-2 or AMSAT-OSCAR-21, hams have had a Mode B transponder in low-earth orbit requiring only omni antennas like ground planes for consistent contacts via satellite. The May 1991 "Hamsats" also had a frequency chart for this hamsat.

Simple Earth Stations

Getting active via satellite can be easy. To work RS-10 Mode A, all that is required is a good 10 meter receiver with a dipole and a 2 meter transmitter capable of CW or SSB with an omni-directional antenna.

Some FM rigs are capable of CW uplink by keying the microphone push-to-talk switch, but many will exhibit excessive chirp with this method. It's worth a try. An alternative is a used, multimode 2 meter rig. One can usually be found for a few hundred dollars at a swapfest. Inexpensive older rigs to look for include the Kenwood TS-700A, the Yaesu FT-480R and the ICOM IC-251. A simple quarter-wave ground plane antenna for 2 meters can be purchased or made from coat hangers and a SO-239 connector. The Lakeview Co. model GP-10-2 by WD4BUM is a very nice ground plane that can be quickly assembled for easy portable operation. Another good choice would be the MAX System ground plane antenna from Cellular Security Group.

On a recent trip out west, I used a Lakeview antenna for many successful contacts via RS-10. My uplink power was about 10 watts through 20 feet of RG-8 coax. For the downlink, I stretched a dipole made from hook-up wire between two trees. The feedline was a short run of RG-58 to a Uniden HR-2510. Although a small MOSFET preamplifier was available, it was not necessary for most contacts. A 12 volt power supply powered the radios, but a battery would have done the job as well.

Operation via the Mode B linear transponder on A-O-21 proved to be just as easy as A on RS-10. Ten watts to the 440 MHz version of the Lakeview ground plane proved sufficient for quality contacts whenever the satellite was above the horizon. A GaAsFET preamplifier was employed for the 2 meter downlink. It wasn't necessary, but it helped during times when the satellite was low in the sky.

Although I didn't try it during the western trip, mobile operation should do very well on A-O-21. A single quarter-wave whip for 2 meters could be used for both 70cm uplink and 2 meter downlink. A diplexer would be needed, but they have become very common in recent years due to the popularity of dual-band mobile operation through FM repeaters. For those interested in building their own, the September 1989 issue of *Ham Radio* presented a very simple, easy-to-build diplexer in the "Ham Notebook" column.

Photo A. WA5ZIB and WA5WOD with portable station in central Texas.

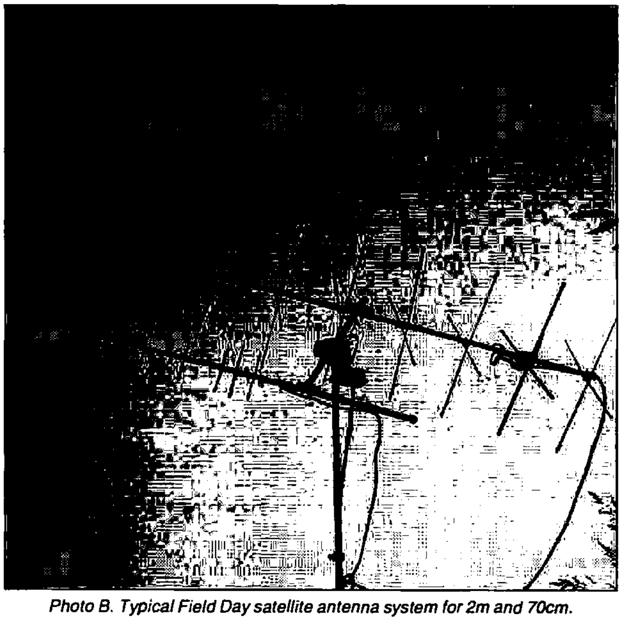

Photo B. Typical Field Day satellite antenna system for 2m and 70cm.

The success of A-O-21 activity with nothing more than ground plane antennas was inspiring. AMSAT-OSCAR-13 was oriented to provide excellent signals after apogee (when the satellite is closer) rather than during. I had been able to hear conversations in the passband with the ground plane and preamp, so I tried the 70cm uplink. Signals were so weak I could barely hear my own CW, but it was there. After several attempts at contacts, a very patient WD6EPV came back with an answer to my call. Ten watts to a ground plane is not much for contact via a satellite 15,000 miles away, but it will work under optimum conditions, and if the operator on the other end has a good system and an excellent ear.

Other Simple Systems

It's not necessary to see how small an antenna system can be and still work for satellite activity. A few hams have put their stations in backpacks and used shoulder-mounted beams to make contacts via the high-orbit hamsats. Others have had simple, yet effective, stations on boats, and several have tried mobile satellite work. Field Day is another opportunity for innovative installations.

The idea is to use available equipment to make contacts via satellite, and add system improvements for more serious efforts as time and money allow. An omnidirectional antenna on 2 meters can be the beginning of a home satellite system with the inclusion of almost any 10 meter rig and antenna. For that matter, the simple 2 meter home antenna could be immediately put to good use making contacts with U5MIR-1, the packet BBS on *Mir* (145.55 MHz FM simplex). Similarly, signals from DOVE-OSCAR-17 and UoSAT-OSCAR-11 can be monitored with simple systems tuned to 145.825 MHz FM.

The addition of at least one beam antenna with azimuth and elevation control marks the beginning of serious satellite activity. Expensive computer-controlled rotators are not necessary. Jack KA5DNP, author of "The Field Day Special—the 'Ray Gun' " in the June 1990 issue of *73*, doesn't use rotators at all, and has DXCC via satellite. Older TV rotators provides excellent service if you need remote control or who wish to pursue fast-moving, low-orbit birds. 73

Everything To Gain

Before we get to this month's topic, let me direct you to the table on page 73 listing those parts source addresses I promised last month. By no means does this list include all of the mail-order outfits out there, but it should give you a starting point. By the way, these names all come from catalogs I have here in my home lab. You, too, can get these catalogs, and most of them are free. I strongly recommend that you get as many as you can.

Now for our next topic: GAIN. What is it, and why is it so important? The foundation of modern electronic technology, including radio, television, the digital computer, and virtually anything else you can think of, is the ability to make a small signal bigger! Without that crucial function, we'd be back to crystal sets and earphones. We call this function "gain," and the devices which perform it "amplifiers."

I'll go out on a limb here by stating that the first device capable of signal gain was the triode tube, invented by Lee DeForest. I think there may have been some earlier, experimental magnetic devices, but the tube was the first to be widely employed. It ushered in the radio age and all that was to follow.

The Signal Itself

Before we can examine the phenomenon of gain, we have to take a look at what we're trying to make bigger in the first place: the signal. What is a signal? A signal is simply a changing voltage or current whose changes represent some kind of intelligence. It is easiest to think of it in terms of voltage.

Imagine a graph where the "X" (horizontal) axis represents time. The "Y" (vertical) axis represents the voltage. As the voltage changes over time, it draws a graph of the signal. That signal may be a sine wave, a pulse, or perhaps many waves whose overall level, or envelope, changes over the course of several cycles.

In any event, the signal will get smaller as it passes through the air in a radio transmission or through wires, because no path or conductor is without loss. (OK, perhaps a superconductor comes close, but we're not living in the superconductor age yet.) In radio, the strength of the signal decreases proportional to the square of the distance from the antenna. In other words, if you go twice as far away as you were, the signal is only one quarter as strong. If you go four times as far, it is only one sixteenth as strong. That occurs because the energy is spreading out to fill the surrounding area, so you are receiving smaller and smaller pieces of it. By the way, that's why satellite dish antennas for TV need to be so big: to collect enough of the satellite's extremely weak signal to be able to detect it.

Of course, radio is much more complicated than the "inverse square" law, which doesn't take into account ionospheric reflection and other phenomena. But at least you can see what we're up against. So how do we make such tiny signals useful? We amplify them, of course!

Two Ways to Make it Bigger

There are two kinds of amplification or signal gain: voltage gain and current gain. That may seem confusing, but it is easy to explain. Voltage gain is when the voltage swings of the input signal to the amplifier cause bigger ones at its output. This type of gain may cause a 0.1 volt peak-to-peak input signal to drive the amplifier to 10 volts p-p. That would be a voltage gain of 100.

Current gain is when the amplifier's output swings are the same size as its input swings, but the output can drive a much lower impedance load before getting bogged down and losing voltage. So, a signal that can deliver 2 volts p-p into 1000 ohms might be reduced to only 0.01 volts if you tried to drive an 8 ohm speaker with it. But a current amplifier can keep it at 2 volts into the 8 ohm load.

Now that we know what gain is, let's look at how it is produced.

Nothing: The Essential Factor

We all know that a tube is nothing more than some metal pieces and a filament inside an airless glass envelope. Nothing magical and theoretically complex like a semiconductor. So why does it exhibit gain?

Tubes use the natural tendency of electrons to accelerate when attracted through space to an opposite polarity. Specifically, if you boil some electrons off a hot electrode (a piece of metal) and put another electrode nearby, and then make the second one positive with respect to the first, the electrons will pick up speed on the journey and slam into the positive electrode harder than they were moving when they left. So what? Well, if you put yet another electrode (called a "grid") near the first one, you can block or let pass the moving electrons by putting a small amount of voltage (your signal) on it. It acts like a gate. In fact, the British still call tubes "valves," because that's essentially what they are.

When the traveling electrons, which are now varying with the signal, slam into the plate, they make it more negative (in other words, less positive) than it was before, and the amount they change it is proportional to how many electrons have been passed by the grid and how fast they were moving. And there you have it: gain! The output will vary with the input, only bigger.

Whew. Now you know why it took mankind umpteen thousands of years to discover this phenomenon. Also, having a vacuum pump helps, because you can't make this work at all if there is any gas (such as air) inside the tube. The electrons collide with the gas atoms and never make it to the plate.

Something Messy

Solid state devices do pretty much the same thing, only they do it not by attracting electrons through space, but by permitting them to migrate through certain kinds of materials which can conduct energy only under certain circumstances. I know that sounds vague but, believe me, the physics is messy and not worth getting into here. Essentially, it all comes down to a gate which either restricts or permits electron flow, along with the ability to magnify what flow there is. In transistors, that ability comes from the generation of "holes" of missing electrons in an atomic crystal lattice pattern, which can then be filled by other electrons traveling from another part of the transistor. See, I told you it was messy. The advantage over tubes is that no hot electrode is required, because the electrons don't have to be projected into space. Also, you don't need a vacuum.

Well, once again we're out of space, so we'll continue our discussion of gain next time. There's lots more to cover. 73 for now.

NEW From Micro Computer Concepts RC-1000 REPEATER CONTROLLER NEW

• Autopatch
• User Programmable CW ID, Control & User Codes & Timeouts

• Intelligent CW ID • Auxiliary Outputs • Easy to Interface • Remote Base/Tape • Reverse Patch • Tailbeeps • 12 VCD Operation • DTMF Decoder with Muting • Telemetry • Control RX • Response Tones • Programmable COS Polarities • Detailed Application Manual with schematics • 90-Day Warranty

Wired & Tested w/manual $239.95

Never Say Die

Continued from page 4

. . .and he knows me too. As does his father, the ex-governor. . .as does ex-governor Sununu and ex-governor Peterson. Bragging again? Nope, I'm explaining how you can help change things. And you won't do it by sitting there like a lump in a bog.

If we can get our schools back on track. If we can get 'em busy teaching science so our kids will be able to cope with the technology of 2000 and not have to call in the Japanese to fix their equipment, we'll have enough young hams to start contributing to the advance of communications again.

Is that a massive sigh I sense? Too much trouble, right? So okay, we're failing our kids. We're turning a blind eye to the educational mess they're in. Just as we are too busy to train our dogs to behave, we're too busy to bother bringing up our kids. Too busy doing what? "Don't bother me now."

Fathers talk with their kids 16 minutes a week. . .and that's the national average. No wonder our educational system is one of the worst in the developed world. No wonder our kids are so much more into cruising, drugs, sex, and beer than amateur radio and other scientific hobbies.

When I start hearing your 10-year-olds on your rig calling CQ, I'll know there's some hope. When I start seeing your kids at hamfests, I'll lighten up. When I start getting pictures from clubs showing bright young faces with calls, I'll find something else to fret about.

Pan Am and Airline History

A few years back I was able to get my father to write a series for *73* on his early experiences in aviation. I tried to get him to write more, since the reader reception was so positive. . .though it wasn't even remotely about amateur radio! But he only wanted to write about the positive things he'd been through and refused to tell the rest of the story.

With Pan Am's recent bankruptcy I got to remembering how much that company had affected my life. Well, how its president, Juan Trippe, had affected it. And Trippe's good buddy, FDR.

My dad got involved with flying right after WWI, learning to fly in 1921 (pilot's license #73) with the Army in San Antonio. I was born the next year and within months he was taking me up with him. I grew up around the big Martin bombers at Langley Field in Hampton, Virginia, where he flew with Jimmy Doolittle. . .the chap who tried to convince the Army that airplanes had a future and could even sink ships.

After leaving the Army he barnstormed for a while and then worked for the Department of Commerce, giving pilot tests and putting together the first guide to American airports. He had commercial pilot's license #89.

This led to his being hired to design and build Philadelphia's Central Airport. Then Jim Eaton of Luddington Airlines hired him as passenger and cargo manager, so we moved to Washington when I was nine. When Luddington sold out to Eastern Air Transport in 1933, he and Jim decided to start a New York to Boston airline. Marine Airlines would use flying boats and go directly from downtown Manhattan to downtown Boston, cutting the commuting time substantially.

The other airlines were enthusiastic about connecting to this new service, so they provided the needed investment. Except for Trippe of Pan Am. He'd been using flying boats on his South American flights and was worried about his turf. He didn 't want any other airlines using flying boats.

Pan American was our only overseas airline at the time, so Juan Trippe cultivated FDR as a friend as a way to help protect this edge. A whisper in Roosevelt's ear resulted in an Executive Order that no airline could own stock in another airline. Today, if a president were to do that, the press would be all over him and raise hell. There wasn't much accountability then, so FDR and Trippe got away with it and Marine Airlines was sunk before it ever got going.

Tough break. Two years of hard work torpedoed. But that's the way it is with entrepreneurs. . .they gamble on an idea. Sometimes it pays off and sometimes a catastrophe comes along and blooie.

Jim and Dad didn't funk for long. They thought big. OK, then how about a trans-Atlantic airline? They got together with the owners of American Export Lines, the largest American steamship line, and convinced them that air travel would eventually eclipse ship travel. This was around 1936, mind you. Pan Am had expanded into the Pacific, so it didn't take a lot of convincing to get American Export to see the writing on the wall.

My father headed for Europe to set up bases for the planes. Most of American Export's ships cruised the Mediterranean, so that's where he spent about a year setting up seaplane base agreements with the governments. I'd get postcards from Oran, Genoa, Alexandria, Beirut, and Tripoli.

I've got a bunch of pictures I took of the PBY they used for the survey flights in 1938–1940. Dad set up a seaplane base in Botwood, Newfoundland, for the summer crossings and others in Belem, Brazil, and in Dakar, Senegal, for the winter crossings. Just as they were getting going with regular passenger service we had a little war, so the Navy used the airline for their purposes.

Trippe was not happy about all this. He kept pushing Roosevelt to have America allow just one international airline. . .Pan American Airways (PAA). It was called a "chosen instrument." With Britain backing BOAC, France doing Air France, and so on, he urged FDR to choose PAA. Roosevelt agreed and shortly before he died he issued an Executive Order saying that no steamship line could own stock in an airline.

American Export, having invested millions in the project, and having had to let the Navy use it through the war, was furious. Trippe offered to buy American Export Airlines, but he didn't offer much. The American Export people said hell would freeze over before they'd sell to Trippe.

American Airlines made an offer, so it became American Overseas Airlines. . .for about a year. Then American sold it to PAA. Sneaky deal. But long before PAA took over, American had eased out the Export management by putting their own managers in over them and taking away their authority. They didn't fire them, of course.

Jim didn't take this second setback well and soon died. My father went fishing. But not for long. Aer Lingus, the national Irish airline, wanted a trans-Atlantic division, so they hired Dad to set it up.

He spent the next couple years building the new airline for Ireland. It meant setting up ticket offices, buying planes, hiring and training crews. . . the works. Then, a few weeks before the inaugural flight, there was an election in Ireland and De Valera was ousted as Prime Minister. The new chap came in promising economy, so he immediately stopped the airline. . . despite tens of millions of dollars in presold tickets.

Dad sold off the planes for them, helped the employees find other work and closed down the operation. A few years later De Valera was re-elected and Aer Lingus asked my father to build Irish Airlines again. He said no. Ireland managed to waste hundreds of millions and set themselves back years with that dumb political move.

A few years ago, when I decided to set up a software operation in Ireland, I visited Jack Kelly-Rodgers, who'd been the president of Aer Lingus and had visited us many times in Brooklyn, and we reminisced over how badly that debacle had hurt Ireland.

Even after three crushing disappointments my dad was game to have a try at building a helicopter plant for Kamman. He took a room in Suffield (CT), coming home on weekends, and organized the factory for Kamman at Bradley Field. It was the first time anyone had gotten the Navy to put up the money to build a factory.

The son of the people he lived with recently got his Novice ticket. . .small world department. And Kamman's son

QSL of the Month To enter your QSL, mail it in an envelope to *73*, WGE Center, Forest Road, Hancock, NH 03449. Attn: QSL of the Month. Winners receive a one-year Subscription (or extension) to *73*. Entries not in envelopes cannot be accepted.

is in the music business making guitars.

Entrepreneurship

While being an entrepreneur doesn't always pay off. . . and never did for my father, so we never had much money. . . it's sure more exciting and fun than working for a large business. Not having money was good training for me. And with both my father and my grandfather being entrepreneurs, it was natural for me to go that route.

Sure, I've made some money, more by accident than on purpose, but that hasn't changed my frugal habits. All of my money has been invested in providing jobs for people as I spin off one new company after another. Some of the people have done well with my money, others have wasted it. . . and themselves in the process.

The huge publishing conglomerate I sold eight years ago has now almost completely disintegrated. None of the seven magazines has prospered in recent years and all but two failed. My huge software firm is gone. Even the book publishing business is gone.

I saw all this happening, but was unable to change the corporate management approach which was at the heart of the failure. The October *Analog* has a fascinating article on what went wrong with the Hubble telescope. Too bad if you missed it. The author points out that all successful scientific endeavors have had one man ramrodding them through. The Hubble was a group-managed project. . . and thus became a horrible, expensive disaster.

The Manhattan Project seemed like a group effort, but there was one man fanatically following every detail. . . Robert Oppenheimer.

Entrepreneurs tend to succeed because they put their whole lives into their work. Groups tend to fail. Just ask the Russians.

None of the seven magazines and other businesses I sold should have failed. None would, I'm convinced, if there had been an entrepreneur running them instead of accountants. Why, it's almost enough to make a person think!

Dan Quayle recently attacked lawyers, pointing out that America has 70% of the world's lawyers. They're an easy target. . . and a valid one. But we need to wrest control of American industries from the accountants as well as the lawyers. Accountants should be there to help entrepreneurs know how they're doing, and should not be permitted to make financial decisions.

Corporations have to file tax returns and this means a horrendous amount of accounting has to be done for the government, which refuses to pay for it. These tax figures are almost useless as far as running a company is concerned. Entrepreneurs need to deal with cash flow, which includes things such as accounts receivable and payable aging.

The League, Again

With no-coders coming into the hobby by the thousands, there could be some opportunities for entrepreneurs to provide Tech-oriented products. But don't get carried away quite yet. While our growth appears to be about 100% ahead of last year at this time, remember that we still only have about 20% of the growth amateur radio experienced for 18 years after WWII . . . until the ARRL pulled the whole works to a screeching halt in 1964. While most of the chaps responsible for nuking the hobby are now dead, I'm not sure we shouldn't remind ourselves now and then of what damage the League has done and how little it's done to promote hobby growth. Sadly, there are thousands of amateurs who truly believe the self-promoting propaganda they put out. I've never loved or hated the League. I've just been amused by those who do love or hate it. That's about as smart as loving or hating the Republican or Democratic parties.

Yes, of course the League does good things. Always has. Unfortunately, as a ham editor and publisher for the last 40 years, I've been privy to the inside skinny on what's really been going on, something few hams outside the industry have any way of knowing. A little quiz: How much do you know about the Doyle letters? He was an ARRL director who really spilled the beans. They were busy trying to cover up that mess for years.

And why did Herb Hoover resign as president of the ARRL? And how was the ARRL involved with W2AOE's suicide? How did a sneaky (and probably illegal) ARRL deal with Hallicrafters completely ruin the ham exhibit at the New York World's Fair? Tell you what—if you'll get off your butt and elect some new and younger directors, I might shut up about the ARRL.

No, I'm not mad at the League. Exasperated perhaps, when I see the things that need to be done that they're not doing. And I sympathize with David Sumner, whose hands are pretty well tied by the directors, few of which have much business experience or detectable foresight.

I was just listening to a tape of an ARRL president giving a talk to a ham club where he admitted under questioning that the published board minutes in *QST* are laundered. Perhaps whitewashed is a better term. Having gotten years of earfuls from frustrated directors, I knew this was true, but I'd heard many true-believers angrily deny that any such skullduggery was possible.

When I asked Budlong W1BUD, the ARRL general manager, why the League was fighting the proposal for RTTY to be permitted below 2 meters, he explained that the League had always fought any rule-making proposal not submitted by them, no matter how beneficial to the hobby. Otherwise the League might lose control. I can't recall when the League has deviated from that policy in the 50-plus years I've been a member. Either you get your rules changed through the League or face an endless fight with them. Years later Bob Booth W3PS, their attorney, confirmed that this policy was still basic.

We succeeded in getting RTTY on the low bands, but it took several years of fighting the League. And look how long it took to get a no-code ticket!

So, following in my father's and grandfather's footsteps, I've been an entrepreneur most of my life. I've tried to help amateur radio grow and be more fun. No, I don't take it very seriously. But then I don't take anything very seriously. I try to call a spade a spade in my editorials and talks and encourage hams to have fun and keep our hobby clean. On that measure I guess I have to admit to being a failure. Oh, I've helped with the fun, but our hobby isn't much cleaner than it was 60 years ago. It isn't much worse, either, so perhaps that's a success, considering how much worse almost everything else in the world seems to have turned.

As my 69th birthday passes, I'm more and more aware of my mortality, with so many of the Silent Keys much younger than me. I'm discouraged that there don't seem to be any other voices speaking up for our hobby. The pages of *73* and *Radio Fun* are wide open for intelligent, creative ideas on improving amateur radio. Hello, anyone alive out there?

New Use for CB!

The Scripps Clinic In La Jolla has been messing around with 27 MHz. Lord knows how they got onto this one, but they've been sticking 27 MHz radiators into the mouths of 30 insomniacs for 20 minutes three times a week. Another 30 got no RF as a control. Wouldn't you know that the insomniacs went to sleep 52 minutes faster than the controls and slept 1.5 hours longer!

The next time you hear some old fossil beefing about CB you can point out that it has at least one sterling virtue . . . it puts people to sleep. No wonder, I often find that just listening to CB puts me to sleep.

Now I'd like to know what power levels they're zapping those insomniacs with. . . and if they've thought of testing 27 MHz against 30 MHz? Who knows, 10m may be an even better sleep inducer.

This bit of esoterica was reported at the annual meeting of the Bioelectromagnetic Society. I'll try and find out more about this for you. I don't have any trouble getting to sleep, but judging from some of the late night QRM, others may. . . so perhaps a 10 meter lollipop could help get you to the Land of Nod.

Are You Bo-ring?

Even packet and RTTY contacts can be excruciatingly boring when you run into a ham who has absolutely nothing to say. A recitation of the equipment, weather report, and signal report don't make much of a QSO. When that happens you know you're up against still another slow-witted proof that they don't give intelligence tests along with the code test.

One of the things I particularly enjoyed about RTTY back some 40 years ago was the ability it provided me to write some interesting stories and store them on punched tape. I've suggested doing this with tape cassettes, but it hasn't caught on. Today it's simple to store any number of stories on floppy disks and download them onto packet or RTTY. . . if you ever take the trouble to put them together.

Have I ever told you about the time when my fast-thinking saved my submarine from being sunk? Or the time when I came that close to being killed by the Shifta while on a hunting safari in northern Kenya? Or the time a drunk tried to stab me in the heart with a hunting knife? Or my strange first contact with China? Or some of my hairy flying experiences with my own seaplane? What it was like when I operated from Swaziland and Lesotho? Or from the king's palace in Jordan? Or the biggest crook I've ever met in amateur radio?

I'd love to have these recorded and quickly available to play, but even DAT tapes take 10 to 20 seconds to cue up. We need something faster, so I'm looking forward to Sony's new minidisc (MD) technology, where I'll be able to record over an hour of stories on a tiny disc and access any track I want in one or two seconds.

Using the same medium I'll be able to use either voice or an ASCII file and dump it via CW, RTTY, AMTOR or packet. I don't know how popular MDs will be for music, but they could be a boon for hams.

Of course I'm presuming that you have something of interest to talk about. That you've seen some interesting movies, watched some interesting TV shows on PBS, read some interesting books. . . etc. Alas, a dismayingly large percentage of the public doesn't or can't read. Plus they've never gone anywhere or done anything.

If you'd get your station set up for a combination of packet and slow-scan, you'd be able to set up whole libraries of short slide shows, complete with commentary, all accessible via a menu by the chap you're in contact with. Then, instead of just telling you about my visit to the Palace of Nebuchadnezzar, a few miles from Baghdad, I could show you some fascinating pictures, too.

Or perhaps you'd like to see how they bake pita bread in Tehran by sticking the loaves to the sides of igloo-shaped ovens? Probably not, eh? Well, how about some slides of sharks, barracuda and gorgeous coral? Or lionfish in the Red Sea? Or my DXpedition pictures from Navassa in 1958 or 1973? This isn't quite practical yet, but it could be within a year if someone would do the software.

A recent letter from Walt AH6HU suggests it's about time for some concentration on developing ham software. We need some macros to simplify log keeping and combine it with QSO files. We need to be able to make satellite or *Mir* contacts without having to shuttle between satellite tracking, log-

ging, and word processing programs . . . loading and unloading, with attendant waits for our struggling processor to wade through the top-heavy software. If you'll get started writing some software we can publish, we'll even help by making it available both on floppies and via our BBS.

The more we can use our computers and other storage systems to enhance our QSOs, the more fun amateur radio will be, both for us and for the people we get in contact with. Let's head toward multi-media, using packet, voice, computer storage, SSTV and so on, gradually getting ourselves into the 1990s in technology. And let's start seeing some articles from you on how to do it.

What's Been Your Contribution?

What are you really good at? Is there anything where you're a local expert? A national expert? A world expert? Any skill or field where you stand out? Or are you satisfied to be mediocre? Are you a star in some field . . . or just an anonymous cypher?

In amateur radio each special interest has its stars: W3CUL for traffic handling; W2QHH for certificate hunting; W6AM for DXing; W2BFD for RTTY; W8JK for antenna designing; W6KG for DXpeditioning; W1FZJ for Moonbouncing; W2KPL for ATV.

What separates the stars from the mediocre? Passion. Passion goads the star into working a little harder and longer than anyone else in one niche. It's surprising how little extra effort it takes to begin to stand out in your community . . . in your company . . . in your club.

I got fascinated by the idea of digital communications (RTTY) back in 1948. By 1951 I'd gotten so fed up with the lack of communications in the field that I started a newsletter . . . *Amateur Radio Frontiers*. Soon I was an "expert" and was asked to do a column in *CQ*! I started giving talks to ham clubs and wrote the first RTTY manual. My RTTY column led to my becoming the editor of *CQ*.

Is mediocrity genetic or is it learned? When there's a call for help by your ham club, are you right up front, anxious to do something? Club presidents are always complaining that 90% of the work for the club is done by 10% of the members. In which group are you?

At work . . . whatever kind of work you do . . . are you satisfied to be mediocre? How many magazines do you subscribe to which will help you learn more about how to do your work? How many books have you bought in the last year on the subject? How about adult educational courses in nearby schools? How about professional symposiums and conferences? If you're not taking them, should you at least be teaching them?

What aspects of amateur radio are you into? Tried packet yet? If so, have you given any talks to your club on the subject to try and get other club members interested? Ditto satellite communications, moonbounce, UHF experimenting, ATV, SSTV, and so on. Or are you a mediocre ham with only the most vague understanding of 90% of what the hobby has to offer? Are you merely a rag-chewer, satisfied to get on the air and mindlessly repeat the same garbage over and over for years?

If you're in sales, could you get up in front of a sales meeting and teach a group of salesmen about selling? If you're a manager, are you up to teaching a management group about managing? Or have you been getting by without really knowing much about your craft . . . without reading about it daily . . . without trying to learn more?

There's a big difference between getting very good at something and becoming a true expert. My rule of thumb has been to work at a new skill or interest until I'm in the top 10% of a group of people involved with that interest. After that, the amount of time it takes to get better at it starts to escalate logarithmically and you're headed toward being a one-interest person.

Let's say you decide for some weird reason to get good at working DX. You'll find there are few guidelines in the ham magazines about this. Even the DX bulletins don't cover the subject. They're almost 100% involved with lists of rare DX stations, their QSL managers, times and frequencies.

Okay, how good do you want to be? Some hams are so totally involved with working DX that they are monomaniacal on the subject. A rare DX station will keep them home from work . . . even from their son's graduation. I'd suggest setting a goal of 300 out of the 400 possible countries. That'll put you well up in the 10% stratosphere in most DX clubs.

If you're going to work 300 countries you're going to need time, good equipment and a lot of expertise. You can make up for any shortcomings in one department by spending more time in another. Howie W2QHH got to the top of the certificate-hunting pile more by dedication to his pursuit than by having a big signal. But a big signal will sure cut down on the time it takes. And it's more fun with a big signal.

It doesn't take much power to get through on a clear channel, so why the kilowatt and the beam? That's to clear the channel. You can't get to be a superb photographer with a Brownie. So figure on spending some money on your interest, whatever it is. Get good equipment. If you're into music, get a damned good hi-fi system. If you're going to rack up a DX score, put up a good, high tower, crown it with a single-band beam, add a kilowatt amplifier, and you're ready to start clearing your frequency . . . to jump into the pile-ups and come out with the prize while you're still smiling.

Your big signal is fine. That's like having a Weatherby for hunting (Weatherby was a ham, by the way). You still have to know where to hunt and how to find that elusive prey. This means getting DX bulletins. It means checking into the DX nets. It means a 2 meter link with other DXers. It means getting damned good at winning DX contests, for that's when some of the really rare spots are activated. That's

when your big signal will pay off.

You still have to learn operating tricks. How to tail-end without aggravating the DX op. How to get your call across fast. How best to come out on top of the piles. How to find the rare ones. How best to deal with list operations.

Sure, I've worked something over 350 countries . . . and I did it without losing my perspective . . . without becoming a DX addict. If you've got a good signal you should be able to work a hundred countries in one DX contest weekend on 20m SSB. I did. Two hundred took me a month. Three hundred a year. From there on I stopped being serious about it and caught the rest by accident.

I went about learning to be a competition driver the same way. I got a good car (Porsche), took lessons from some top racing drivers, and practiced on some top race tracks.

Same with rallying. I got the best in equipment, drove for some top navigators to learn, then developed my own rallying system and then started teaching it to other navigators. The next thing I knew I was importing special watches and computers for rallying and advertising them in the car magazines. I developed my own special tables for navigators and those using my system were usually the winners.

Once you're over 300 countries it's time to ease off and start using your big signal for less predatory purposes. It doesn't hurt to have that signal for RTTY or packet. Or you might get involved with contests and start collecting awards. Once you get good at contesting, it's fun. Oh, it's a real bummer for the hams who just want to ragchew, but contests only come on about 50 weekends of the year, so don't pay any attention to those milksops. Ignore them. Crush their pitiful bleats with your Big Signal.

Once you get used to no longer being mediocre you'll find yourself getting elected president of your ham club . . . or any other club you join. And that's fun, too. It's a challenge. Now you're in show business. And once you're more than mediocre you're going to be a lot more interesting to talk to on the air. You're going to have interesting things to say. You're not going to be stuck way down there in that sorry rut of reciting your name (oops, pardon me, handle), rig, antenna, weather, and over to you.

40 Years?

Yep, I started publishing my first ham magazine 40 years ago, in June 1951 . . . complete with long editorials. I did it because I couldn't get anyone else to do it . . . and it needed to be done.

In 1936 I was just another fat 14-year-old teenager. Then an angel . . . or perhaps a devil, depending on your perspective . . . stepped in. My boyhood chum, Alfred Lake (Alfie), and I were in church (Dutch Reformed) one Sunday when a chap came in carrying a big carton of radio parts. Rather than throw them away he gave 'em to Alfie. Alfie took one look and asked if I was interested. Sure!

We read about angels coming or being sent down by God to do good things. But the Devil himself seems to get involved with the bad things. I guess he doesn't have as big a staff . . . or maybe as much to do. Yet, when you consider the number of bad things happening compared to the good, El Diablo must run a very tight ship. I don't believe for a minute that government employees go to heaven, but God must be using a similar management system.

Anyway, the box of radio parts got me to checking my *Popular Mechanics* back issues. I found an article on building a cigar-box radio which used my parts and put it together. Then either one of the best or the worst things of my life happened . . . it worked! I was hooked.

My high school (Erasmus, in Brooklyn) had a radio club (W2ANU), which I joined. Naturally I started studying for my ham ticket . . . and eventually became W2NSD.

Cut to 1948. After four years in college and another four in the Navy (WWII), I was working as chief cameraman for WPIX-TV, the *Daily News* station in New York. I set my 2m ham station up on the 37th floor, complete with a 16-element beam on the roof. Big stuff in those days.

But hey, what was that weird beedlebeedling up on 147.96? Turned out to be John Williams W2BFD and a bunch of other RTTYers talking with each other. Hmmm, Teletype, eh? It didn't take long before I'd built my first RTTY unit and was pecking away on a Model 12.

There was quite a crowd on the channel, all with automatic start and stop RTTY systems so they'd work just fine unattended. We had clocks on 'em which allowed us to selectively call any individual at so many minutes after the hour. If we turned on his machine during the one minute interval we could hold it on and leave messages. Several of us even built in a system to get an answer-back acknowledgement that the messages had been received. Not bad for over 40 years ago, eh?

I was having so much fun that I wanted others to find out about it so they could have fun too. I tried to get John to start a newsletter, but the best he'd do was send out bulletins on RTTY. Well, that wasn't going to help attract newcomers! We needed an RTTY newsletter.

In 1951 I got a job as a TV director at WXEL in Cleveland and, wow, there was a mimeograph machine. Within days I had the first issue of a Teletype bulletin in the mail to everyone I knew who was involved with this obscure hobby. I called it *Amateur Radio Frontiers* and published it monthly until I took over as editor of *CQ*.

My newsletter soon got me a RTTY column in *CQ*, and that led to me becoming the editor in January 1955. Then, when I got fired in January 1960, I decided to stick with publishing. The first issue of *73* came out in October 1960.

Continued from page 79
It was that confounded box of old radio parts that started it all. When friends found I was interested in radio they started dumping old radios on me. I had a ball taking them apart and saving the parts. If I'd only known that putting 'em up in the attic for 50 years would turn them into solid gold...! But then, I'd have done a lot better job of saving my Big-Little books, my baseball cards and old marbles too. Heck, I could launch several more magazines just by selling all that old junk.

One legacy of my many years spent at the workbench building things is a twisted pelvis. I tended to stand on my right foot and this eventually gave me a slight permanent twist and a resulting weak back. I suppose it was a reasonable trade-off, because I had a wonderful time building rigs, receivers, audio amplifiers, RTTY, SSB, VHF gear and so on.

Parts? Did I have parts? I had tons of 'em. It took two moving van loads to get 'em to New Hampshire when I moved up from Brooklyn in 1962. I had thousands of tubes, cabinets full of resistors, capacitors, switches, relays, sockets, connectors. When I needed something I'd get a dozen or 50, just to be sure. I didn't just have switches or connectors, I had 33-drawer cabinets of switches and connectors.

I saw the beginning of the end when transistors and ICs appeared, so I held a couple of mammoth auctions and dumped everything at cents on the dollar, more interested in finding good homes for my parts than getting money for them. You don't sell things you love for money. I still remember every one of those parts...the Sangamo transmitting capacitors, the vacuum capacitors, those cute little 454 acorn and 9001 peanut tubes, remember nuvistors? How about those 815s? 826s...two 807s in one envelope? One rig had 203Zs, another 813s. My 2m kW had CX-125s.

Oh, there are plenty of things to build these days, but not rigs. Home building can't begin to compete with the economies of scale of commercial manufacturing. Individual hams have a hard time out-designing whole labs of engineers and technicians at ICOM, Kenwood and Yaesu.

With parts so hard to find it's easier to turn to Ramsey and other kit suppliers and let them shop Asia for us.

My first job after college was as a radio announcer/engineer. That was fun, but it didn't seem to have much of a future. I felt the same after trying television for three years. But my basic need was to get people to share the things I enjoyed, so publishing seemed like a good medium for me.

I've been at it ever since, encouraging kids to get into ham radio...trying to get hams to find out how much fun RTTY, SSTV, packet, 10 GHz, DXing, DXpeditioning, moonbounce, OSCAR and so on can be. Yes, I'm a nag.

When repeaters came along I drove tens of thousands of readers crazy pushing them to try 2 meter FM and repeaters. I did the same with SSB when that first came along. And computers too. I not only badgered my ham readers to try computers, I started one computer magazine after another, driving over a million readers to learn more about 'em and have fun. I published dozens of books and hundreds of software packages.

Now I'm sharing my love of music with my *Music & Audio Reviews* magazine, urging them to just dammit listen to ragtime, bluegrass, marches, folk, and a wide variety of ethnic music. And, as usual, I'm succeeding.

At 69 I have what, maybe 10 years more to go at best? Well, that's 10 years to help people have fun. And since one of the least fun things is to be poor, I also push anyone who'll read or listen to get off their butts and start making money. It's out there by the carload, just waiting for anyone with the guts to go after it...and that's fun too. It's exciting!

Making money doesn't take brains or even a college degree, all it takes is working in a direction which has good odds for a payoff...and working harder than most other people. At 69 I'm taking it easy. Heck, I seldom work more than half a day any more. Twelve hours. I can't let work eat into my hamming time, right? Hmmm, as the publisher of *73*, perhaps I should count hamming as work. No, that would put me on overtime.

Beating The Bushes

I'm heartened by the growing number of clubs which are actively trying to recruit new hams...particularly youngsters. My apologies for being such a nag about getting more hams. I'll be even more heartened if (a) you start sending me some photographs of your newly licensed youngsters and (b) you increase your efforts.

If your club would like to start Novice or no-code Tech classes, but you don't know how to get 'em out of the woodwork, I can give you some hints. Like hint #1 is to make sure you have interesting meetings so that when you get newcomers to come they won't be turned off forever about our hobby.

While I know it's possible that an old-timer could actually force himself to be nice to a youngster and manage at least a strained grin for a few moments, you might do better to retire your fogies to the back row and get someone with life left in 'em to front for the club. You old fogies can get mad at me if you like, since I'm probably older than you.

Okay, now how do you drum up those newcomers? Well, there are two ways to go about it, so do both of them. You can go hunting for them in the most likely places...on CB and in schools. It won't hurt to see if some members have kids who haven't yet been turned into fanatical ham haters.

I'd get a team of two or three club members to scout the CB channels, looking for fresh blood. If you get to 'em before they get disgusted and quit, you'll have a chance. Invite them to a club meeting. And when they come, for heavens sakes say hello to them. Talk to them. Get your members to come out of their huddle over at the side of the room and be gracious hosts. Jeeze, do I have to explain the fundamentals of good manners? Judging from many of the clubs I've visited, yes, I do.

I gave a talk about amateur radio to the fifth graders in the local school. They started a ham club and I'm still getting letters of appreciation from the kids. I wrote about that and asked if anyone had a spare rig for the club. No one wrote. Tsk. If you won't even part with a rig you're no longer using, at least put in your will to have your widow send one of your rigs to help out the kids.

If I can do it, so can you. So get in touch with your local schools and ask the principals if you can talk to the fifth or sixth graders about amateur radio. Mention that kids need to learn about technology...and they'll learn best if they are enthusiastic about it.

Yes, I know, that's old ground. Sure, but the fact is you haven't done it yet, so I need to remind you. When it comes to things you should be doing, but which take a little initiative, I have to nag the heck out of you. Now get moving! Heck, if I can find the time, so can you. You're *not* busier than I am.

Publicity

One of the easiest things you can do is start getting people acquainted with amateur radio by getting it mentioned in your local papers...and on the radio. If you know how to do this, it's simple. If you don't, you're in for a lot of frustration.

First, you need to have some sort of flimsy excuse for sending out a "release." This can be when a member of the club makes DXCC, WAS, wins a contest, when the club does Field Day, has a picnic, auction, hamfest, or other event, graduates some new licensees, holds a transmitter hunt, provides communications for a race, rally, walkathon, has a celebrity speaker (like an astronaut...no, I'm not a celebrity ...of course I could immolate myself on the front lawn of the White House in protest over the loss of 40% of 220 and become a celebrity, but who needs a talk from a roast ham?).

Do some brainstorming for possible news items. How about a club member making a 10,000 mile QRP contact with a rig he can hold in the palm of his hand? Or maybe someone has made DXCC over a weekend? Or WAS in one night? Or WAC in 10 minutes? How about some contacts with hams in the USSR? Or the Mideast?

Did I ever tell you about the time I worked W7IMW/C7 in Tiensin, China? He was running 1/10th watt to a signal generator and a longwire on 10 meters! Tell me about QRP. And yes, I worked a hundred countries on a weekend, worked all states one night, and made WAC in ten minutes one morning on 20 meters. No, I didn't call the newspapers...but I should have!

It's unlikely the paper will send out a reporter or photographer, so you'll want to get a club member to take the pictures...black and white, not color, for most papers. Color pictures don't do well in black and white.

Perhaps I'm presuming too much if I suggest that you may have someone in the club who can write. Many of the letters I get are on spiral notebook paper, written in something between hieroglyphics and Sanskrit. The easier a release is for an editor to use, the more likely it is to get published. I hope that's not a revelation.

This means you appoint a literate club member to write the release. Print it out double-spaced, keeping it concise and to the point. Include the floppy disk so the editor won't have to re-keyboard it. The less editing it needs, the more likely it is to see print. Tell the story simply and clearly. Leave out the ham lingo. Try to work in how much fun everyone had at whatever you're writing about and give a contact name and phone number, both for the editor and for any readers wanting information about club meetings.

Once you have your release ready to go, complete with some photos (each with a caption taped to the back...do not use a ball pen), it's time to call the editor and tell him you're sending a release. Tell him if he has any questions to give you a call.

Then, when you think he's had time to get the release, call again and see if he has any questions. You can then ask if he's going to run the story, so you can tell the club members and their families to look for it.

Be sure to include the fact that the club is giving license classes and that newcomers are most welcome. Then see that they are.

One more thing, try to get across the idea that you're having fun.

If you keep getting our hobby into print and mentioned on the radio, eventually the concept that hamming is fun and accessible will seep into the public consciousness. With over 3,000 ad messages a day hitting us, it isn't easy to get through the clutter. It takes imagination and persistence. One time doesn't do a thing. Two times doesn't either. It takes a continuous barrage to penetrate.

When I lecture college students on entrepreneurialism I always ask for a show of hands of those who know what amateur radio is. I'd say that about 5% of them even have a clue. And it's our fault that we have an almost totally secret hobby.

One of the things I pleaded with you ARRL members to do is to lean on those old dodo directors you keep electing every two years and get them to have the general manager set up an honest-to-goodness PR department to go after both national and regional publicity for the hobby. And keep leaning until they stop double-talking and get into action.

Okay, you have your marching orders, what else do you need? Let's get cracking...and don't forget to send me a copy of your stories when published so I can start giving your club credit. 73

HAMS WITH CLASS

Carole Perry WB2MGP
P O. Box 131646
Staten Island NY 10313-0006

The Berens River Connection

As a ham radio operator, I am always fascinated with the way every radio contact can produce its own unique fun, excitement, or information. As a teacher using ham radio in the classroom, I continue to be impressed with the myriad of spin-off lessons that can be generated from the simplest of radio contacts.

Without even realizing it most of the time, hams are always demonstrating skills other than radio expertise. Determination, diplomacy, good will, cooperativeness, and helpfulness are but a few of the very real observable traits most hams convey to the world 24 hours a day. How wonderful it is to be able to point this out to children who are at the radio.

When Bill Peckham VE4AAL, principal of the Berens River School in Manitoba, contacted me, neither one of us could have predicted the excellent exchanges our schools would be involved with. Bill and his students tried to check into our CQ All Schools net for months. We always called for them, knowing that they would be there listening for us. When we finally did make contact, it was especially meaningful to all the youngsters. Phrases like "ham determination" and "never say die" were heard in my classroom for days as the children discussed the contact.

The children, being natural goodwill ambassadors, quickly set up a pen-pal exchange with their counterparts in Canada. Many class sessions in the next few months were spent on producing a schoolwide video to send to Bill and his students. We continued to be surprised and amazed at the differences in our respective schools. When my students in Staten Island learned that Berens River had a total population of 1800 people, their jaws literally dropped. The school population in our 6th, 7th, and 8th grade intermediate school alone is 1800. It was great fun for me to watch the expressions on their faces when they heard these facts on the radio. The video tape and letter exchange will undoubtedly be remembered for a long time. If you are lucky enough to be an instructor with a ham radio in your classroom, don't cheat yourself and your students out of this kind of terrific learning experience.

From VE4AAL: Report on Student Ham Radio

Berens River is an isolated community located 180 miles directly north of Winnipeg, Manitoba's capital city. The community is accessible by road only during January to March, when vehicles can drive over the frozen lakes, rivers, and muskeg. During the summer, Lake Winnipeg offers passage for barges and fishing boats. Excellent airport facilities allow small commercial airlines to fly in and out on most days. Isolation is a factor shared by many northern Manitoba communities.

Berens River First Nation Reserve has approximately 1800 residents, most of whom are Treaty Indians of the Saulteaux Tribe. Many of the students speak Saulteaux fluently, and have the opportunity to study their language at school. School programs encourage respect for their local heritage and culture.

Berens River School is operated by Frontier School Division No. 48, and costs are shared with the local Native Band. Frontier School Division is the largest school division in total area, in North America, and covers many remote communities. The Area 3 superintendent has been most supportive in encouraging new programs, like the Ham Radio Pilot project, which will hopefully help advance communications in these northern communities. Student interest could develop into lifelong hobbies, and perhaps lead into various careers. Many students have been introduced to radios because their parents operate marine radios on their fishing boats in summer when the boats head out on Lake Winnipeg. During winter, when the fishermen use bombardiers on the frozen lake, marine radios are essential equipment.

In the fall of 1990, the ham radio shack in Berens River School received a new rotor and control for its large-sized, heavy beam antenna. The Berens River Band Council gave the school a large steel tower on which to mount the beam. This antenna allows global coverage of the 10, 15, and 20 meter bands. Another antenna, an inverted-vee, allows contact on the 40 and 80 meter bands. The ICOM 735 transceiver provides state-of-the-art radio contact with the outside world. The ham radio pilot project in our school includes classes in grades 5, 6, and 7. This program has been slow at getting off the ground, but more volunteer students are getting involved from these three classes. Morse code keys have been received to practice code so the students are well on their way toward learning the alphabet. The students often meet during regular class time and have been spending more time during lunch hours and after school.

The highlight of our ham radio program thus far has been the 6th and 7th grade students' recent contact with Carole Perry's students in Staten Island, New York. We had often tried to connect with them last year, but without success. For most of our students, it was the first time they had spoken into the mike. By the time we made our second clear (5/9) contact, the students were able to give their names

Photo A. Berens River School Principal Bill Peckham VE4AAL at the school rig.

Photo B. Fifth grade students watch as Kingsley McDonald speaks on the radio.

Photo C. Eighth grade students Farah Berens (at the mike) and Arnold Disbrowe learn how to make QSOs.

phonetically over the mike, and were quite excited with the matching of pen pals. Some students were apprehensive about their poor writing skills, but were reassured that they would receive extra help with letter writing. They were willing to try, and have nearly completed their rough drafts. We've received our first pictures of Carole's students, and have Polaroid pictures of our own students in the mail.

The students are eager to learn more about New York City, our contact area. They weren't too sympathetic with Carole when she mentioned the snow storms in New York, as we had experienced blizzards with −40 degrees Celsius during the holidays. The wind chill sometimes made it more like −50 degrees. Students in Hollywood, California, talking on Carole's net during our first contact certainly couldn't comprehend these conditions.

Dave Place, a guest instructor, recently visited our school while in our community on business. He explained to the students the theory of how messages are transmitted from the radio through the atmosphere to other locations. Within minutes, Dave had several students talking to people in England and Wales, as well as listening to people in Italy. What a way to integrate studies! It is most encouraging to hear students who have never had much academic success spell their names phonetically on the radio, and do their best writing a letter to a new pen pal!

Our next challenge is to have our 5th grade students talk with Larry, a teacher in Hawaii I made contact with several times last June, and his students. Through such contacts, our students are beginning to understand the concept of time zone differences.

My latest challenge to the students is the offer of a free ham station to the first student who passes his or her Novice ham exam. One young lady asked me what I would do if several students passed the exam at the same time. Do they each get a station? I hadn't thought about that!

In the future, we will have to address several needs. First, we need to identify and obtain learning materials (books, publications, Apple IIe computer disks, and video tapes) suitable for our students, to help prepare them for their Novice ham radio exams. Second, we need more instructors, as the increased interest among other students means an added strain on the instructor's time.

Considering the advantages and educational benefits to the children of the Ham Radio Project, the time, money, and effort makes everything worthwhile. 73

All hams are encouraged to use this column as a focus and reference, and to send in suggestions and ideas so that we can share and network with each other on ways to promote amateur radio to capture the interest of people of all ages.

UPDATES

Pseudo CW Filter

See the above article in the June 1991 issue, page 18. Several pinout numbers in the original schematic need to be changed to reflect the PC board pattern: pinouts 4, 5, and 6 should be 10, 9, and 8, respectively on U3. See the Figure for the corrected schematic.

Although the CW filter will work with the incorrect pinouts above, it will not work without the junction of C8 and C9 going to ground. Note the ground in this new schematic. Note, however, that the PC board layout is correct. TNX John Korzenko KB5JOZ for calling this to our attention.

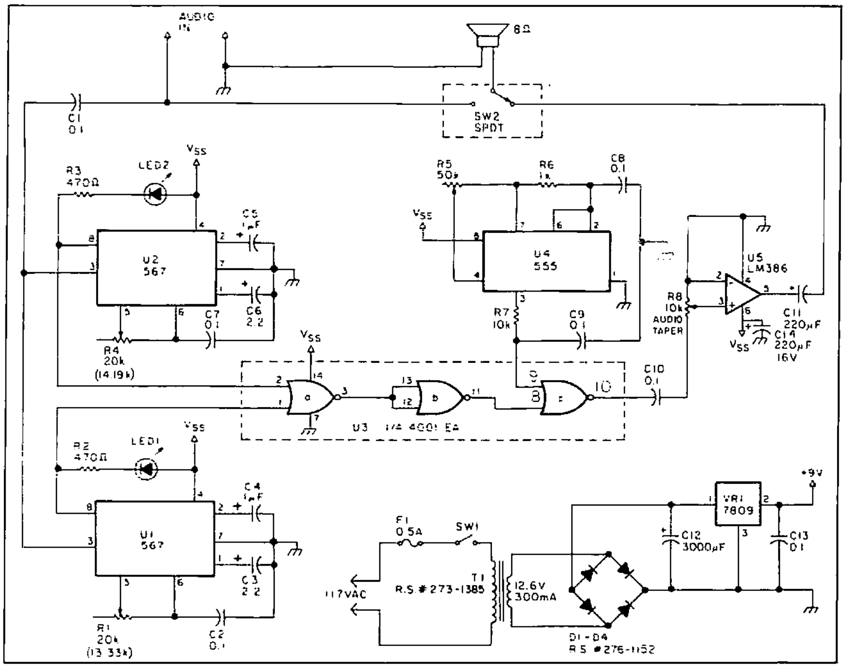

Figure. Corrections for the Pseudo CW Filter are shown in blue.

Poor Man's Packet

See this article in the August 1991 on page 8. Wm. Kresl WB9BBC writes that he and Jim N9EDX have discovered an easier method of aligning the modem RX BIAS adjustment. The procedure is as follows:

1. Disconnect the 33 ohm load resistor (R6) from the RX audio input line.
2. Temporarily jumper the TX audio output line to the RX input line.
3. Enter the PMPTEST software and run the 600 Hz transmit audio test.
4. Place a scope on the RXD data line of the modem chip (pin 8). The transmit data consists of perfectly timed square waves (duty cycle wise).
5. Adjust the RX bias pot (R1) for perfect 50% HI and 50% LOW duty cycle pulses. This is a critical adjustment made simpler with the scope.
6. After adjustment, re-connect the RX load resistor (R6) and remove the temporary jumper.

Says WB9BBC, "I also used a scope to set the TX audio output modulation to the HT to approximately 20–50 mV (peak-to-peak). I have built and tuned up five modem boards since, and the procedure works fine." TNX Wm. Kresl WB9BBC. 73

BARTER 'N' BUY

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The *73 Flea Market*, Barter 'n' Buy, costs you peanuts (almost)—comes to 35¢ a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to the *Barter 'n' Buy*, Sue Colbert, Forest Road, Hancock NH 03449 *and get set for the phone calls.*

Deadline for the February classifieds is December 1, 1991.

HAM RADIO REPAIR CENTER, quality workmanship. Solid state or tube, all makes and models. Also repair HF amplifiers. A-Z Electronic Repair, 3638 East, Indian School Rd., Phoenix AZ 85018. (602) 956-3024. BNB220

Notes from FN42

I am writing this during the last week in August. As we all probably remember, there was an attempted coup in the Soviet Union to remove Mikhail Gorbachev from the Presidency of the Soviet Union. As usual with world events, hams were involved in the happenings.

In the United States we were shown video footage on the television of what was happening in Moscow. One of the stories showed the office of Boris Yeltsin, President of the Republic of Russia. A portion of the report showed that an ICOM IC-735 was being used for communications on 14.167 MHz, a ham allotted frequency. [Editor's note: We just received a newspaper clipping from *The Morning Call*, an Easton, Pennsylvania, publication, on amateur radio operator Romeo Stepanenko 3W3RR, a resident of Moscow who kept Yeltsin in touch with the world during the three-day seige. In a FAX to William N. Goodman K3ANS, at whose home Stepanenko was a guest last year, Stepanenko writes, "Listen to R3A on 14.175 and 7.044, the only real and trusty information." Yuri Brajenko, who helped set up the shortwave station, said that the station also collected and retransmitted information from other parts of the country on the people's reaction to the attempted takeover. Helen Brajenko translated Russian to English on the air for Stepanenko. Yuri, Helen, and Stepanenko spent three days and three nights with a team of Russian ham radio operators on the sixth floor of the Russian Parliament building, keeping the world informed. TNX K3ANS for sending us this information.]

About the same time, the eastern seacoast was visited by Hurricane Bob. Usually a hurricane that could cause heavy damage would receive top billing in the media, but it came in second to the attempted coup in the Soviet Union.

A week following the hurricane, I was watching a program on one of our PBS (Public Broadcast Service) TV channels which showed the effects of hurricanes and what can be done by business owners and homeowners to minimize the damage from the winds and rain. In the program, a weather forecaster asked for more information from an affected area. He was talking to a person sitting in front of a radio. The readout on the front of the radio showed 14.325 MHz, a ham frequency in the United States.

I have listened to that frequency in the past during hurricanes and have heard the National Weather Service (NWS) in Miami, Florida, receiving reports from hams on conditions there. That information was very important because the data from the NWS in the affected area was unavailable due to a power outage.

Sometimes I have heard the reverse; the NWS has sent warnings to the affected areas by ham radio because all other communications channels were out due to weather related damage.

This points out that hams have been useful in many different ways in the past, and must be ready to assist at any time when the need arises. Now is the time to prepare for the future.—Arnie N1BAC.

Roundup

Japan From *The JARL News*: The International Telecommunications Union (ITU) has decided that a Plenipotentiary Conference will be held in Kyoto, Japan, for five weeks, commencing September 19, 1994. This is the first time that the ITU Plenipotentiary Conference will be held in the Asia-Pacific region, and more than 1,200 participants, originating from as many as 164 countries, are expected to attend.

Though the agenda for Japan has not yet been decided, a special plenipotentiary committee will hand over the subject of ITU reorganization, and the new direction of ITU will be discussed. Equally of importance will be the election of a new secretary general.

Taiwan Official Visits JARL. Mrs. Tsai S. Luan, a senior member of the Telecommunications Bureau of Taiwan, together with her husband, visited JARL's offices and met with the Secretary of the IARU, Region III, Mr. Fujioka, and the latter explained in general about amateur radio in Japan, and elaborated on JARL's various activities as well.

Their two-day visit (June 18 and 19) was, according to Mrs. Luan, very satisfying as she was given full details to her inquires about the Japanese system of qualifying amateur radio operators and licensing.

Australia

This is just a quick preview of the coming months. Briefly, there is agitation to remove the CW requirement completely for HF access, and replace it with further theory (e.g., advanced communications); and following the development of examinations to accredited examiners, the WIA looks to be the sole supplier of such papers, thereby putting a few noses out of joint. Finally, the packet protocol wars are raging again. This time it's ROSE vs. NET/ROM. Stay tuned for the latest!

Ministry of Communications News Speaking for the Ministry of Communications at the annual General Membership Assembly of the IARC, Mr. Alon Bar Sela 4X1AB praised the radio amateurs who came forward and volunteered their services at the Ministry's monitoring station in Jaffa, as well as those who relayed traffic for the American servicemen and women stationed in the Persian Gulf during the crisis and war.

Alon assured us that the Israeli delegation to the 1992 World Administrative Radio Council (WARC) will be a staunch supporter of amateur radio, and will do its best to defend our bands against the various interests who wish to take more slices of spectrum away from us.

The Ministry of Communications caught some pirates who had been causing interference to amateur communications, and seized their equipment and filed criminal charges with the police. Mr. Bar Sela stressed that it is difficult to catch such culprits, and even once things are before the courts it can take much time before sentences are passed. Nonetheless, being caught and having equipment seized is an unpleasant experience and a punishment in itself, as well as a deterrent to others. The Ministry would like to see more participation from the amateur community in this ongoing hunt.

4X1AB cited the opening of a portion of the 50 MHz band for radio amateurs in Israel, and said that this was a step in the direction of further increasing amateur activity here in that frequency range. In closing he congratulated the young amateurs who had just recently passed the Novice examinations, and said that with the expansion of Novice privileges we were seeing a greater influx of young people into our ranks.

Activity Thrives at the IARC Home Every Thursday evening the new IARC headquarters are bustling! Each week at this time interesting lectures are delivered mainly, but not exclusively, on topics related to amateur radio. Topics covered up to now include computer programs, packet radio, antenna tower construction and safety, electromagnetic radiation, and aircraft accident analysis.

Behind the scenes, organizing these different interesting talks, is Tuvia Greengross 4X4GT. It is said that Tuvia is an expert in arm-twisting, convincing members of our ham community, which it turns out is blessed with numerous experts in many fields, to give an evening's talk on the subject of their expertise.

Morse Camp in Haifa! For the first time in the history of Israel, a day camp is being held for the express purpose of teaching Morse code. From July 7th through the 18th, from 8 a.m. to noon, the course, sponsored by the City of Haifa, is being held at Beit Miller on

LONG ISLAND, NY The Radio Central ARC will sponsor HAMEXPO at Suffolk County Community College, Long Island Expwy. exit 62-Nichols Rd./County Rd. 97-1 mi. north. Free parking. VE Exams, seminars, forums. Admission $5 at the door. Tables $20 in advance. Send to ***Radio Central ARC, PO Box 680, Miller Place NY 11764.*** For info call ***John Mark KB2QO, (516) 689-6336*** or ***Jo Ann Coletti N2IME, (516) 399-1877.***

NORTH HAVEN, CT The South Central Connecticut ARA will hold an indoor Ham Radio and Computer Flea Market at North Haven Park and Rec Center, 7 Linsley St. Sellers admitted at 7 AM, buyers 9 AM-3 PM. Tables $15 in advance, $20 at the door. General admission $3 per person. Talk-in 146.01/.61. Table reservations must be received with check by Nov. 1st, no reservations by phone. For reservations and info, SASE to ***SCARA Flea Market, PO Box 81, North Haven CT 06473,*** or call ***Brad WA1TAS, (203) 265-6478*** between 7 PM and 10 PM.

NOV 16

PLYMOUTH, MA The Mayflower ARC will host a Flea Market at the Plymouth Memorial Hall Bldg. In Plymouth Center (RT3A) from 9 AM-4 PM. Tables are $10 in advance, $12 at the door (if available). Sellers admitted at 8 AM. Donation $2, children under 12 free. There will be a Microwave/ATV demo. Talk-in: 446.625 and 146.55 simplex. Mail SASE and check with table payments to ***M.A.R.C., PO Box 766, Plymouth MA 02360.*** For info call ***Jon WS1K, (508) 746-0162*** or ***Jim NM1F, (508) 747-2224,*** eves.

MONTGOMERY, AL The Montgomery ARC will host the 14th annual Montgomery Hamfest in Garrett Coliseum at the South Alabama State Fairgrounds on Federal Dr. Free parking. Free admission. Set-up begins at 6 AM; doors open to the public from 8 AM-3 PM. FCC Exams start at 8 AM. Bring original and a copy of your current license, picture ID and $3. Talk-in on 146.24/.84, call W4AP. Ragchew 146.32/.92 (with phone patch, •up/#down), 147.78/.18, 449.50/444.50. Flea Market reservations are not required. Special Hamfest rates at Villagers Inn, I-85 at Ann Street ($28.50 plus tax, up to 4 folks). Phone the desk at ***(205) 834-4055*** or ***800-328-7829.*** For reservations at the Coliseum Motel, across the street from the Hamfest, the desk phone is ***(205) 265-0586*** or ***800-876-6835.*** For more info write to ***Hamfest Committee, c/o 2141 Edinburgh Dr., Montgomery AL 36116*** or phone ***Phil, (205) 272-7980*** (after 5 PM CST, or any reasonable hour on weekends and holidays).

NOV 17

CHICAGO, IL The Ham Auction of the Chicago ARC will be held at the DeVry Inst. of Tech., 3300 N. Campbell, from 12 Noon until all is sold. Door opens at 11 AM for sellers.

NOV 23

BILLERICA, MA An Amateur Radio and Electronics Auction will be held from 11 AM-4 PM at 300 Concord Rd. Free admission and parking. Seller check-in at 9:30 AM. Buyers admitted at 10 AM. Commission is 15 percent, $1 minimum, $30 maximum. No commission for owner buy-back. Contact ***Ellot Mayer W1MJ, (508) 851-0183.*** This event is sponsored by Bull HN 1200 RC and the Waltham ARA.

NOV 24

WHEATON, IL GMRS of Illinois, Inc., will hold our annual "Winterfest" at DuPage Co. Fairgrounds on November 24, 1991, from 8:00 a.m. to 1:00 p.m. Tables are $10 in advance, $12 at the door. Tickets are $4 in advance and $5 at the door, outdoor flea market spaces are available at no charge. Plenty of parking, no tables in hallways, no crowding. For more info call ***Bob (708) 690-1492 or write: GMRS of IL, Inc., 2077 W. Roosevelt Rd., Wheaton IL 60187.***

RICHMOND, VA PC Fest Computer Shows, Inc. will hold a Hamfest at the Virginia State Fairgrounds from 10 AM-4 PM. Admission is $6 for adults, children under 10 admitted free.

NOV 30

APACHE JUNCTION, AZ The Superstition ARC, WB7TJD, will hold its annual Hamfest at P&M Rodeo Grounds, NW corner Brown Rd and Meridian, from 7 AM-3 PM. Admission $1. Tailgate space $3 per space, overnight parking, no hook-ups. Talk-in: 147.72/.12. Contact ***Chuck Kruppenbacher, (602) 986-3060.***

SPECIAL EVENT STATIONS

NOV 2

URBANNA, VA The Rappahannock ARA will operate K3RZR, 1330-2130 UTC, to celebrate the 34th annual Urbanna Oyster Festival. Operation will be in the following bands: 20 meters: 14.140/.280; 40 meters: 7.240/.280; 80 meters: 3.860/.880. For certificate, send QSL and 8½ x 11 SASE to ***Phyllis Haxton N4VZC, PO Box 396, Burgess VA 22432.***

NOV 2-3

COOKEVILLE, TN The ARS of Tennessee Technological University, will operate Station WA4UCE from 1400-2400Z Sat. & Sun., in conjunction with the University's 46th Homecoming Celebration. Operations will be on the General portions of the 80, 40, 20, 15 and 10 meter bands and the Novice portion of 10 meters. For certificate, send QSL and 9 x 12 SASE to ***TTARS, Tennessee Technological University, Box 5262, Cookeville TN 38505.***

CHARLOTTE, NC The new Amateur Radio Education Center at the Discovery Place Science Museum will celebrate its opening by hosting Station W4BFB from noon EST Nov. 2-noon Nov. 3. W4BFB will be operated by the Mecklenburg ARS, primarily on phone in the bottom 50 kHz of the General phone subbands on 75, 40 and 20 meters, and around 28.400. For QSL and Certificate, send QSL card and a 9 x 12 SASE with two units of First Class postage to ***Ralph Eubanks KK4FC, 6021 Coatbridge Lane, Charlotte NC 28212, USA.***

NOV 3

LEGARTO, TX To help celebrate the medieval flavored AbbeyFest I, the Benedictine monastery of Corpus Christi Abbey and Benedictine Retreat Center, the Corpus Christi ARC, will operate station W5MS near the shore of Lake Corpus Christi, in Live Oak County, from 0000-2359 Z. Frequencies: Lower 25 kc phone subbands of the 84, 40, 20, 15, and 10 meter bands; RTTY on 20 and 15 m; 146.96-, 147.08+, 444.70+. For a QSL certificate, send QSL and a large SASE to ***Br. Dominic Mazoch, OSB, N5TCB, NCR 2 Box 6300, Sandia TX 78383.***

NOV 4-10

PENSACOLA, FL The Serious Hams ARC will operate 4 Nov.-10 Nov. to celebrate the decommissioning of the USS Lexington AVT-16. Operations will be in the lower portion of the General 80-15 meter subbands and 28.350. For certificate, send QSL and a 9 x 12 SASE to ***Mike Brown N4MAD, 519 S. Edgewood Cir., Pensacola FL 32506.***

NOV 7

CLINTON, NC The Sampson County ARS will operate Station AB4TT from 1700-2400Z for the Sampson County Expo and Pork Festival. Operation will be in the lower portion of the General bands. For certificate, send QSL and SASE to ***SCARS, PO Box 64, Clinton NC 28328.***

NOV 9

MEMPHIS, TN The Delta ARC will operate W4BS from 1400-0000Z in celebration of the grand opening of the Pyramid on the Mississippi. Look for operation at 14.305, 21.320, 28.455. For a nice, full color QSL, send SASE to ***Delta ARC, PO Box 16343, Memphis TN 38186-0343.***

Continued from page 88

Shoshanat HaCarmel Street, home of the 4X4HF radio club. Intended for youths, the fee is a mere 105 shekels (US$45).

Those diligently participating for the fortnight, even with no previous knowledge of the code, should gain at least enough proficiency to pass the Novice ham test. A fully-equipped ham station is on the premises, and part of the time will be devoted to operating procedures. We hope to get a follow-up this fall, when the Ministry of Communications exams will be held. Will this project yield a crop of new young hams?

Ham Party. Any party among Hispanics is an excuse to get together and have a good time! Early in my stay here a friend was telling me about an upcoming party, and I made the mistake of asking him what time it would be. He replied, "To have a party here you don't need a specific time, only a day."

One purpose of a recent party was to award five insignia to stalwart members of the ham club. The requirements were: to have been a member of the club at least 15 years, and to be at least 65 years old. Another purpose was to award the "Diploma Islas Canarias" to all the EA8 ops who have earned it; fulfilling the requirements are much more difficult for EA8s than for hams in other parts of the world.

Plaques were also awarded to several collaborators and the president in appreciation for their many services to the URL. Several foreigners, such as YL (XYL?) CO5CB, a Cuban, received plaques as reminders of their stay among us.

Furthermore, an unusual note of thanks was given by the YL members of the URL to one of their members of whom they are very proud for her awards and achievements during the short time she has been participating in the contest world. In addition to some pretty amazing individual feats, she led the URL "contest team" to several world championships. Those of you who read this column may know that we can be talking of none other than Elsa EA8BVH. And so her YL companions awarded her a keepsake plaque.

Another reason for the party was to celebrate the formal reopening of the club after extensive remodeling of the building and grounds. This was attended by officials of the state government, as shown in the photo. The party was a great success with lots of good and lively music until the wee hours of the morning, but without the fireworks like we have on Independence Day in the United States (O.K., Luisa?). In all, a memorable night of April 27.

Oh yes, my call now is EA8/N5KVB, which is the uniform style in the Common Market countries for temporary licensees. I'm still in that category. Until next time, 73.

The November Blahs

As most of you know, the spring and fall months of the year, centered around the mid-March and mid-September equinoxes, are traditionally the best times for DX propagation. However, as the months progress toward the solstices of December and June, conditions gradually deteriorate on the long-distance HF hauls.

November is one of those in-between months, yet a time for contesting, too. What can we say about this November? Well, among others things, YY—EEE—CCC—HHHH and Blah, with a capital "B." That's a bit of an exaggeration, but I really don't see a lot of good days for HF band propagation.

The poorest conditions will be centered around the 8th of the month, and again around the 25th. The rest of the month will exhibit fair conditions, with occasional good days, as shown on the calendar, around the 18th through the 22nd. . .possibly five days in all.

But, On Other Bands. . .

What's sauce for the goose is not necessarily sauce for the gander, and I expect that the bands between 30 and 160 will be quite reasonable for night-time DX, and grayline (along the path of dawn and sunset) propagation will provide some excellent contacts.

The bands between 30 and 10 meters, will not be "too shiny," as a local friend of mine says. Of course, these are just guesses based on some pretty advanced crystal gazing, and I hope my pessimistic prognostications are wrong by a mile or more. Certainly, for the past six or eight months, Old Sol has confounded the experts and created some unusual propagation conditions. There is no reason to believe that that will change soon, so be aware that anything can happen, and possibly will . .from great to rotten!

Feedback Wanted

On the poor ("P" on the calendar) days, we may experience anything from radio blackout to difficult-to-read signals on the HF bands with loads of QSB. Perhaps some of the lower HF bands won't be as greatly affected. Characteristically, the signals on poor days will not have the sock they have on good days. On the days marked fair ("F" on the calendar), you can expect some good DX contacts between selected areas, but not everywhere. I wish it were not so, but that's the way it looks. I hope that some of you will call or write and tell me how wrong I was.

WWV at 18 minutes after the hour can be your guide to "conditions for the next 24 hours," but you'll find that even they don't always hit the mark. Look for low Boulder A (below 10) and Boulder K (below 3) and high Solar Flux (about 200) for your best chances. Let me know how it works out for you! 73

State of the Shack

Since moving out on my own, I've had what could be called a "shack" in three separate locations. One was a corner of the bedroom in a tiny apartment in Hamden, Connecticut. The next was in a basement room in Weare, New Hampshire, and the latest (and best) is in a ground floor room in my home in Hillsboro, New Hampshire. With each location, the possibilities for my shack have become better and better—more room, more isolation from household and radio interference, better antenna possibilities, less chance of causing TVI. So, how come my shack always looks like a garage sale?

Actually, comparing my shack to a garage sale is doing a disservice to garage sales. My shack is usually much worse.

Since my shack also serves as my home office as well as my home recording studio (4 tracks of analog and 8 tracks of digital), I suppose I should cut myself a little stack. Still, I must be honest and admit that it's not the amount of equipment. If it were all arranged in an organized manner, it would all be usable AND neat. Most of the stuff in my shack is neither.

Desk #1 holds my basic HF and packet stations. Nothing fancy, just a modern HF transceiver, antenna tuner, an HT and 30 watt amp, multimode controller, computer and monitor, plus a telephone, microphones and other accessories. Since I test a lot of ham gear for *73*, I usually have at least one extra HF transceiver set up in a temporary position. This means that my Drake TR-4 must give up its place on desk #2 and is relegated to the floor next to desk #1 (behind the closet door, next to the spare microphone stands). Also on desk #2 you will find at least one 2 meter/440 MHz transceiver (but usually two), a couple of HTs and assorted batteries, chargers, etc. Moving around the room, you'll find the recording equipment—an electronic keyboard, and a stand for the rhythm composer (what they used to call drum machines before they became so complicated and realistic sounding) recording and processing gear.

All this stuff, when stacked up neatly, is not a problem. The problem is that it seems that everything in the room requires at least two strands of cord or wire to make it operate—one going in and one going out. The transceivers must each have an antenna and microphone. The recording gear must have microphones, as well as a patch cord in between every processor. The packet station and computer have more wire than some Southwestern cattle ranches. To this maze of cable we must add a power cord for each and every piece of gear. Of course, because there is SO much gear, I had to add a few AC terminal strips/surge suppressors, which are nothing more than the independent contractors of the cord world. They don't connect to anything. They're just cords for cords' sake.

Along with this prime shack real estate comes a nice, sizable closet for shack use only. This closet can be walked into. This closet has two rows of shelves lining three sides. This closet has its own separate AC circuit and light switch. This closet is bigger than some of the apartments I've lived in. This closet is entirely, one hundred percent, with not one cubic inch to spare—full. Full, full, full. Full to the very threshold of the closet door—a door which does not close because the fullness is too full and is starting to enter the room (which, as we've already established, is full).

I promised my wife that I wouldn't just throw my shack together haphazardly this time. When we moved into this house, I promised her I would leave the stuff set up on the desk until I could arrange the room into a permanent and pleasing arrangement. I have kept this promise. The room is still set up temporarily. The walls are bare of any posters, charts or maps. The closet is still full of boxes to be unpacked (boxes full of more wires and cords, I'm certain). Antenna wires enter through open windows. The 20 amp power supply is in the same exact spot it was placed on the day we moved in. The only difference is that it now has red and black wires snaking out from behind it.

I know my life would be a lot happier if I would take some time to organize my shack. The longer I wait the more difficult it is to begin, because a shack is not a static thing. It is a living, breathing, GROWING entity. It has a life of its own, and the longer you have it, the bigger it gets. A new piece of gear comes in and the box gets thrown on the floor (I'll store that box just as soon as I clean out the closet). A new boom microphone is installed. I'll run those cables neatly next weekend, but right now I'll just leave them where they fall. Look up an address and the *Callbook* gets a new home on top of the stack of other reference books I swore I'd return to the shelf. After all, it's only temporary.

After the "never put anything back where it came from" sickness I suffer from, the other affliction I must confess to having is the dreaded "never throw away a piece of paper" disease. Since I like to keep notes on just about everything, the amount of loose paper displayed in my shack at any one time would probably be a cause of some concern to the local fire marshal. I have pieces of paper with net frequencies (no net names, mind you—just the frequencies). I have pieces of paper with the settings of my antenna tuner for each band of operation and each antenna—even antennas that have been taken down and are currently living somewhere in my closet. I have pieces of paper listing items for sale, obtained from local swap nets and packet bulletin boards. I'm not looking for any new gear, you understand—I simply must write down any potential bargain. I have pieces of paper containing the orbital data of satellites that have long ago burned up in orbit. I have pieces of paper with telephone numbers—no names, just telephone numbers. I have pieces of paper containing directions to places I've never been to and have no intention of ever visiting. Paper grows on my desks and floor like a fungus. I've tried everything—spraying, washing with bleach, dehumidifiers—nothing works. Maybe there's something about RF frequencies that is conducive to yellow legal pad paper growth.

I must admit that there are some positive aspects to my shack's constant state of chaos. I can operate several bands and modes at once. I've often had 2 meter packet, HF RTTY, 440 repeaters and HF sideband all going at the same time. If the muse hits me, I can wade through the snake pit of cables to my 4-track tape recorder and within minutes record a potential hit song for posterity. I have faithfully kept every packing box from every piece of gear of any kind. If anything ever has to be shipped out for repair, I'm prepared (I've been a ham for 20 years and have only had to ship back one HT for repair, but you never know). With all cables and wires exposed, I can change configurations in an instant. Hiding the wires neatly behind the desks and along the baseboards would mean I'd only have to rip them up whenever I wanted to move things around. Since the bookcase is on the opposite side of the room from my operating position, it is more convenient to stack the books on my desk. After all, I'm sure that I'll need to check that WWII-era *ARRL Handbook* again in the near future. Why bother putting it back on the shelf?

Plus. . .since the bookshelf is now empty. . .I can bring in a few more books! 73

NEVER SAY DIE

Wayne Green W2NSD/1

Aspen '92

Anybody who has to be told twice about the Aspen Ham Colloquium in order to get him to decide to go, probably shouldn't go anyway. We don't need any wishy-washy namby-pambies clogging up the works.

The ham business is in trouble and action is needed. Yes, I said ham business. Any of you commie fellow travelers who still believe that socialism is better than capitalism have your head so far up your. . . er. . . armpit, that you need some fresh air. Non-profit? That's the ticket to bureaucracy and lousy service.

As I pointed out last month, it's this non-profit baloney which has so badly screwed up our postal "service" and our educational "system." The sooner we take these public projects private, the sooner we'll start getting some productivity. Just look at the terrible mess our non-profit ARRL has made of our hobby! They destroyed the American ham industry 25 years ago, from the manufacturers down to most of our ham stores. Now they're non-profiting away in Newington while technology is squeezing us out of our frequencies. I'll take for-profit and the merciless marketplace every time for efficiency.

When we use the capitalist system we vote every day with our dollars. And this works for every range of products, from Rolex right on down to Timex. They both keep just as good time, one's just flashier than the other. Private schools can provide better educations than public for every economic level. Once we changed to public schools in the last century our literacy rate dropped and it's never come back up to what it was.

The 16th Annual Winter Ham Colloquium will be in Aspen February 1–8th. Gonna be there, skis and HT in hand? We'll save a chair at our table for you.

Doing Something

Not everyone is sitting on their. . . er. . . laurels. I see in *EDN* that Bob KØDYH is starting a science club in Wichita to stir kids' imaginations. Where are the experimenters? "They're all around us, just waiting for the opportunity to grow," says Bob.

He's lined up mentors to help the kids learn about aviation, electronics, amateur radio, computers, photography, astronomy, and so on. The local Lions Club will help finance National Science Fair projects.

Good idea. . . so how about getting something similar started in your area? Or perhaps as an activity of your ham club?

I remember, way before I discovered amateur radio, I had a great interest in science. I read everything I could get on rockets and space travel when I was around seven years old. I'd have loved a club like that. When I was eight I got a huge chemistry (Chemcraft) set for Christmas. My grandfather even built a workbench to go with it. I had a ball with the chemistry set and built my first radios on that same workbench when I was 14.

How about it? Our kids need all the encouragement they can get. Or would you rather see them dragging their untied shoelaces around the malls, with nothing much to do but cruise? If I ever develop any job openings for experienced cruisers I'll be able to fill them a thousand times over.

Radio Therapy

A chap in New Jersey has discovered a way to ease pains, such as those from arthritis, with low frequency audio modulated radio frequencies. Since he wants to put the device on the market, he's not given any details. He says it also works on horses with pulled tendons and other pains. I'll try to find out more.

Scientists have been gently zapping cats with 2m RF, modulated at the brain frequencies in the 3–15 Hz range. The field strengths used are on a par with what we normally experience when we use our HTs. Even at these low powers the results with the test group have been markedly different from the control group.

No, they have no inkling so far as to how brains demodulate the 2m energy or why the resulting low frequencies have such a powerful effect on the performance and reinforcement of behavioral patterns of the animals. These experiments are certainly going to get me to use remote mikes with my HTs from now on. . . particularly if any sub-audible tones are being used.

This work shows how much we have to learn about the brain. . . and about the effect of electromagnetic fields on cells. It's interesting that many of these experiments are well within the resources of the average amateur, the only stumbling block being a lack of curiosity.

Electricity has been gaining ground in medicine in recent years. It's used now to help the healing of bones and soft tissue, in many cases healing bones which have been broken for many years. Transcutaneous electrical nerve stimulation (TENS) is used to reduce chronic pain. Electroacupuncture is helping the treatment of heroin and cocaine addition. . . it even helps smoking withdrawal and jet lag, and improves learning and memory.

My thanks to Dr. Adey K6UI, a leading researcher in this field, and to the newsletter of the American Institute of Stress for the above data.

DXpeditioning

As I was reading a short item in Chod's *The DX Bulletin* about a group going to Albania, it got my juices up. Lordy, what fun that'd be! Gee, I wish some of these DXpedition groups would remember poor ol' Uncle Wayne when they're deciding who they want with 'em.

Well that's my reaction. . . what's yours? Do you get the urge when you read about DXpeditions? Do you say, "Dammit, that sure would be fun!"? Or has a defective gene or irresponsible parental upbringing grounded you? Or perhaps you feel family responsibilities have permanently clipped your wings?

I don't care how busy I am or how important work is, if I get invited on a really good DXpedition, I'll have my bags packed in minutes. Should I bring along my cute little ICOM 735? How about some antennas? What else do we need? My passport is at the ready!

No, I'm probably not the fastest operator in the world. . . though I think I am and am willing to tackle the pile-ups from the DX end with anyone who wants to challenge me. I'll work those piles, right on down to the mobiles and QRP, and I'll still rack up contacts faster than anybody else with my system. I'll even try not to get testy when the Goliath Big Gun DXers insist on not waiting their turn. Aha, but will they ever get a QSL? Heh, heh. Unk Wayne is merciless with bullies.

So this group is headed for Albania and monumental pile-ups. . . and I'm sitting in New Hampshire writing this damned editorial, watching the first hints of red in the sky over Crotched Mountain as the sun starts working its way up. My barefoot 735 is sitting at my elbow, waiting. . . patiently waiting, perhaps hoping to be packed away for use in some fascinating spot.

Sure, travel is expensive. Well, it isn't anywhere near as expensive as it seems if you do some planning. Like getting an airline credit card and racking up as many free miles as you can. I use it as much as possible for company expenses, so I've got enough free miles saved up to circle the earth a few times.

Clothes? Heck, there aren't any dress codes for most DXpeditions. Oh, you don't want to look like a homeless person. Some plain old Banana Republic stuff will do fine. That's what I wear most of the time anyway.

You're probably not going to be DXing from a country with a Hyatt hotel. . . unless you're heading to Sabah, where I recommend the Kinabalu Hyatt. Great spot to visit. . . particularly if you'd like to do some diving too. The diving there is almost beyond description in terms of excitement. And one more thing, you don't even have to bring a rig. . . the local hams couldn't be more friendly, so they'll like nothing more than to let you sit at their rigs and work about 10,000 Japanese for them . . . plus maybe 5,000 Indonesians. . . if you'll handle the QSLs!

My first DXpedition was back in 1958 when six of us went to Navassa. We first planned on Clipperton. I still have the FO8AS call I got for that trip. . . finally got to use it in 1966 when I visited Tahiti, where I used FO8AA's station.

I got the call KC4AF for Navassa and we had one heck of an adventure. I've got to tell you about that sometime. We went through a hurricane and almost crashed on a reef getting there. Then we came that close to getting killed when we stopped at Haiti. You'll love the part where I have to dive in shark-infested waters to retrieve some dropped antenna elements.

That's part of the excitement of DXpeditioning. You're going to rare spots and you don't know what's going to happen. Sure, it can be dangerous, but that's part of the excitement.

Other DXpeditions can be luxurious. . . like the time I operated for a couple of weeks from King Hussein's summer palace. It doesn't get any more luxurious than that. . . complete with a king for company on a ham-to-ham basis.

Of course the burning of the American Library in Amman the day before I got there and the stoning of our embassy made walking about downtown not particularly wise. Another American ham ignored the warnings and managed to get beaten up by a couple PLO soldiers. But then he was Jewish, took pictures of the soldiers, and his wife was wearing a miniskirt. . . three very big no-nos in Jordan at the time.

I can't understand why you haven't gone on a DXpedition yet. It's fun and

Albania Success

The International Amateur Radio Union (IARU) team of operators/instructors returned in early October from a successful operation in Albania. The ZA1A team was given the honor of establishing amateur radio in Albania and training 12 Albanian students to carry that seed further. During the expedition over 71,000 contacts were made. Thanks to the ZA1A project, Albania is no longer a rare DX country and will continue to be active. On October 8, the ARRL DXCC desk approved the ZA1A operation for DXCC credit. The NCDXF is aiming for the shortest ever turnaround in QSLing for any major DXpedition. They started shipping out cards as of October 26. The QSL address is NCDXF, P.O. Box 1, Los Altos CA 94023. Please include two SAE/SASEs. TNX *Erkki "Eric" Heikkinen OH2BBF, Martti Laine OH2BH and Yaesu USA.*

Business on the Bands?

FCC Rule 97.113, "Prohibited Transmissions," could be changed to permit "personal business" communications, including ordering pizza by autopatch. At the recent ARRL National Convention held in Saginaw, Michigan, FCC Private Radio Bureau Chief Ralph Haller N4RH startled listeners with this proposal, which he says was in response to numerous requests from the ham community to broaden the range of amateur communications. The Commission indicated that it was open to the filing of a request for a rules change that would address certain aspects of quasi-commercial use of amateur radio spectra by hams. Among the possible changes would be: allowing hams to conduct personal and club business over amateur radio; increasing access to amateur radio for local government activities and nonprofit organizations; permitting greater latitude in the gathering and dissemination of news, even for the media, by hams through amateur radio; and permitting payments to educators who operate amateur radio stations for educational purposes. The proposal would also permit hams to retransmit other radio services, such as the Voice of America, WWV, and NOAA bulletins.

Says Haller, "As frequency managers, we feel overly bureaucratic when we have to tell you that you must not use your unused Amateur Service frequencies for non-amateur purposes. After all, the real anti-exploitation rules are those rooted in your respect for the principles for which your frequencies are made available to you, and by your good judgment." *[Unused Amateur Service frequencies?]* When traditional uses of the amateur bands are insufficient to "completely occupy all available amateur spectrum," amateurs should be allowed to use "inactive" frequencies for these almost-commercial operations. This would be on a secondary, noninterfering basis with all other amateur radio communications. These secondary communications would be limited to areas falling under FCC jurisdiction, and where international regulations do not take precedence. The question is: What are the implications of this proposal, and if such a proposal were accepted, how might it change amateur radio? TNX *W5YI Report, Vol. 13, Issue #20, Westlink Report, No. 611,* and others.

Museum Station W4BFB

On Saturday, November 2, the Amateur Radio Education Center at Discovery Place, Charlotte's Science Museum, North Carolina, opened its doors. Opening on the same day were an OMNIMAX Theatre and America's largest Spitz Space Voyager Planetarium.

Station W4BFB, under the direction of the Mecklenburg Amateur Radio Society, invites and encourages all licensed hams to use this fine equipment.

The Science Museums of Charlotte accept tax deductible contributions for the purchase of more radio equipment and station supplies. Contributions also enable them to conduct radio license classes. With a contribution of $100, your QSL card is permanently sealed in plastic and mounted on a wooden panel inside the station for all to see.

For more information, write Science Museums of Charlotte, Inc., 301 North Tryon Street, Charlotte NC 28202 or call (704) 372-6261.

Ham Arrested for Owning Ham Gear

Eric Dobrowansky KA2YKC has been indicted by a New Jersey grand jury on charges of having amateur radio gear in his car that can receive police dispatch channels, which violates New Jersey Statute A2A 124-4. The police channels are adjacent to the 2 meter band. Dobrowansky was arrested late last year by the Cranford police while trying to assist that department in its hunt for a jammer of its police radio communications. His mobile ICOM IC-901 transceiver receives on the frequencies of 136–174 MHz.

The indictment angered the New Jersey amateur radio community. New Jersey hams were already involved in a major political battle to overturn the 30-year-old law under which KA2YKC was charged. The replacement measure, New Jersey Assembly Bill A-3044, or the "Mendelsohn Law" after ARRL Hudson Division Director Stephen Mendelsohn WA2DHF who has been spearheading its passage, would make possession of mobile scanners a criminal offense only if the device was used in conjunction with the commission of a crime.

While hams in the community are deciding what to do, or have perhaps already engaged in doing some of the ideas they have thought of (picketing the P.D.? getting on "Inside Edition"? forming a motorcade equipped with banned gear and driving around town?), Eric Dobrowansky KA2YKC has refused a court plea bargain that would have permitted him to enter a no-contest plea. Instead, he has elected to demand a jury trial. He is represented by ARRL Volunteer Counsel John Norton N2IOB. If convicted, Dobrowansky faces up to a year in jail and several thousand dollars in fines, or both. TNX *Westlink Report, Number 610.*

Let's Talk Radio

A growing number of TVRO (satellite dish) listeners have been tuning in and discovering a very intriguing audio subcarrier. This audio show is called *Let's Talk Radio,* and operates every weeknight from 6 p.m. Eastern till past 2 a.m. (9 a.m. till 2 a.m. on weekends). It features live call-in discussions about amateur radio, TVRO, and shortwave listening, along with a wide array of regular talk show hosts covering just about any topic (usually between 9 p.m. and midnight). Operated by Jim Bass of Syracuse, New York, the listening audience covers most of North America! You can tune into the show by looking at Spacenet 3, channel 21 (S3-21). You'll probably see a scrambled picture, so just turn off or unhook your videocipher unit, tune into the 6.2 MHz audio subcarrier, and join in the fun.

In addition, Jim has an HF receiver at his home which he uses to uplink various amateur radio nets to the satellite subcarrier. Currently he uplinks the ATV net every Tuesday night at 9–10 p.m., various swap nets (usually between 8–9 p.m.), and the weekend TVRO HF net. Anyone who would like more information, or who would like Jim to uplink your net or special activity, should contact Jim Bass, c/o Let's Talk Radio, P.O. Box 254, Syracuse NY 13215. Or call him at (315) 673–3752.

Tropical Hamboree

Every ham is encouraged to bring a young nonham to the Youth Forum on Sunday, February 9, at the Tropical Hamboree in Miami. Carole Perry WB2MGP, famous teacher of amateur radio to young people and conductor of the Youth Forum, also needs **good speakers and presenters under 18 years of age.** Write Carole at P.O. Box 131646, Staten Island NY 10313-0006. (If necessary, you may call Carole at 718/983–1416.) For information on the Hamboree, write Chairman Evelyn Gauzens W4WYR, 2780 NW 3rd St., Miami FL 33125.

LETTERS

From the Hamshack

Orville Gulseth W5PGG, Minnetonka MN I was thinking about sending a subscription to *73* to my grandson, who is nearly 13 years old and just getting started in ham radio. (This is the third generation of hams in the Gulseth family.) Then after I saw the picture of WK3N's QSL card on page 87 of the September 1991 issue of *73*, I decided not to. That spoiled an otherwise very good issue.

Orv, in a few months your grandson will discover girls all by himself and we'll get the subscription from him. You must have a great time censoring all his newspapers and magazines and keeping him away from the TV. Imagine what would happen if he ever saw Murphy Brown! . Wayne

W.E. Beckman WA9JIE, Buffalo IL I have a problem I haven't been able to resolve and am now requesting the help of the amateur fraternity. It's the computerized equipment in my Lincoln Town car that puts out millions of harmonics, and makes a royal mess on my 10 meter HR-2600 transceiver. I haven't dared try my Icom 730.

Remedial steps included good grounding of the equipment to chassis, running RG-8/U coax directly from the car battery into the transceiver with ground strap to coax shield near both the battery and rig. No success. I have put ferrite beads on all power and speaker leads inside the rig. Still no success. (Ran out of beads and could not do the mike leads.)

With the computer chip becoming more and more prevalent in our society, more problems are going to arise. Hopefully some of the hams out there have found a tried and true way of getting rid of all this chirping in their mobile rigs and would like to pass that information on. I'd hate to have to build a Faraday cage around the darn thing; I'm hoping to find an easier solution through my fellow amateurs.

Wolfie, my Toyota Previa van is marvelously silent and handles better than the Lincoln. That's one way to cure all that hash. . . . Wayne

Mark Cronenwett KA7ULD/6, Santa Clara CA After being inactive for several years, I am very happy to see that you are still around. Your editorials are the very first part that I read then and now. I can see that things must not have changed much.

Your editorial in the September issue was great. The part about clubs was excellent. I remember when I joined the local club In Montana. At 17, I was the youngest member; the next closest was about to retire. I didn't like it much after a while.

I have no problem with heights and climbing towers, and I am also very helpful by nature. So I found myself doing a lot of tower work for all of the members of the club who suddenly found they couldn't do it for themselves.

Now I am debating about joining a club or not. I have noticed on the local repeaters that no one will talk to you if you don't belong to the club or group. I originally stopped because I was getting harassed for being a pirate station. Fortunately, that hasn't started again.

Mark, what did you get in return for climbing towers for the geriatrics, a hearty handshake? If they make it worthwhile in some way, no problem. You don't owe 'em free work. Same thing with a club. . . if it's fun, then join. It's that simple. If it isn't fun, forget 'em. And if they don't want you on their repeater, put your own on, and don't let 'em use it. No, better, send me their calls and I'll print 'em in my new Ham Hall of Shame. . . . Wayne.

Kevin KD4CNH, Key West FL I can't begin to tell you how much I enjoy your editorial in *73*. I think you speak for the majority of us new and future hams. I love the part about the fogies. It reminds me of the "I had to walk five miles to school, uphill both ways, always three feet of snow on the ground," saying. I'm an avionics technician for the Navy, and agree with you when you say most don't know what they are talking about. I just believe if you can't say good things about a person, don't say anything. If you're ever talking Florida, give me a call on 10 meters. The 2510 is always scanning! And I love to talk; but make sure you have some time to spare!

Kev, baby, if you don't have anything good to say about a person, write an editorial. . . Wayne

Robert Dickson N4UBK Mr. Green, if it was not for your efforts, I would have been "out of there" a long time ago. Did you know that *73 Magazine* is the only ham publication in the military bookstore on Ramstein AFB, Germany? I read only *73*, beam *[?]* and *Funk Amateur*, which are excellent mags, but if I had to pick one, it would be your *73*. Keep up the hard work.

Don Norman AF8B, Elyria OH The no-code Technician license is changing amateur radio rapidly. Although a recent *QST* analysis says that 90% of new exams are for no-code, it doesn't fit my experience. Seems more like 40% of total exams to me.

Almost all no-code Techs that I have met are working on the code, and I have had two pass their 13 wpm in VE sessions I've worked.

If the hobby is to grow, we need more VE sessions. No matter where a session is held, candidates appear. I have assisted in three sessions in Gilmer County, West Virginia, and no session has had less than 10 candidates.

I suggest *73* magazine do some material on 6 meters. This was a lot of fun in the late fifties. Suppose a 6 meter rig like the Uniden 2510/2600 were available. Seems like a natural for the no-code people.

Norm, ol' boy, I've been hoping that the last ham on 6m would write something for Radio Fun *so we'd get more activity there. It's a wonderful band. . . . Wayne*

Robert A. Willingham N5UYA, Tularosa NM You *[Wayne]* inquired in your note how I had been received on the air. This is hard to quantify. I can say that nobody has been openly hostile to me; I've head a number of derogatory remarks about us "codeless Techs" voiced on the air among some of the "old-timers." They don't think we can operate correctly. Believe me: All the nonsense and bad procedure isn't just on 20 meters! I don't think most of these know-it-alls could pass a test on the FCC regulations, much less Morse code! All of my QSOs have been on 2 meters so far, and I'd say the "friendly vs. unfriendly" has been about 50-50. As I say, nobody has been openly hostile, but I've been given the brush-off more than once. I find that the other "codeless Techs" are always eager to find a friendly voice. I might add that while this part of the country is sparsely populated, we've got a lot of 2 meter repeaters available for use on the surrounding mountain tops and a couple of linked systems, one that stretches from Texas to California. The result is that I hear a surprising amount of activity in the "scan" mode.

As far as reception in other areas, that hasn't been extremely warm either. I don't have any close friends among the local amateur community, but a lot of them know me on sight and now know I am licensed. Nobody has invited me to a meeting of the local club. I went to the local hamfest a few weeks ago and mostly all who would talk to me were selling something. I did run into a guy I took the examination with and he seemed to be glad to have someone to hold a conversation with.

There was one notable exception. I walked up to the ARRL booth and introduced myself to the section manager, Joe Knight W5PDY. He extended to me what I thought was a heartfelt welcome to amateur radio. (I've heard Joe on the air a lot, on 2 meters, and running the net on HF, and I think he is a genuinely nice guy.) I guess the ARRL isn't all bad, but we knew that anyway.

In general, I think a lot of these old-timers don't realize the value to the hobby a lot of us "codeless Techs" could be. Just think of the repeaters, satellites, and other high overhead goodies our money could help finance. Your magazine might become as thick as the Japanese ham magazine you mentioned in one of your editorials. To give you a little bit of my technical background: I've operated my own two-way radio shop, ran a telephone construction company, consulted for AT&T Long Lines and Mountain Bell in the common carrier microwave area. I engineered and built a lot of the private and industrial microwave systems in the southwest. I've done a lot of broadcast engineering work, including building an FM station from the ground up in El Paso, Texas. I've had, along with all this, extensive experience in the data communications field.

No, not everybody has had the background that I have had, but just think of the computer hobbyists out there who could add their knowledge to the pool.

As far as operating on the ham bands, right now I'm confined to 2 meters. My next step is to get involved with packet. I've got an IBM compatible computer already, so all I need is a TNC. I don't know about ATV; I don't have anything worth looking at, and nobody would want to look at me! I would like to explore the microwave region and use the amateur satellites, having had a lot of experience in those areas. I've got mixed feelings about trying HF. Look at the people you have to associate with down there! I'm glad we of the sub-human species have people like you out there beating the drum for us.

Ed Libera, Jr., WT1W, Palmer MA I have been licensed for one year now, having attained the Extra class license in just under seven months.

I read *73* every month, and I find that between the articles and columns, spiced with just enough advertisements, your magazine is a very good buy for $2.95. I don't want to subscribe, however, because I like to visit the YL who runs the local newsstand.

Your editorials, I find, do illustrate some of the nonsense that I have already observed in my new-found hobby. It's an ugly thing, the fact that some hams have been operating for so many years in the same modes, on the same bands, talking to the same people about the same things. Just listen to 75 meters AM, you'll find some don't even acknowledge the existence of SSB. Then you have the politicians, schizophrenics, drunks and dopers. Why does such an enjoyable hobby attract such weirdos?

I know people who spend all their air time on either 2 meter packet or windbag repeater rag-chewing, always talking about the same things. I get sick of being told that if I buy UHF and microwave equipment I won't have anyone to talk to. Then you get these guys who hear new operators on local repeaters and yell at them rather than trying to coach them.

I have been nominated for vice president of our local club, and will probably be elected. All the older members want someone younger (I'm 33) to have a place in club management. I am sworn to get new members and educate new hams, and to get these guys to talking about things besides "my dog's cataract operation."

Kathleen Smith VE3WKW, London, Ontario I look forward to getting your magazine every month at the newsstand. I love your editorials. I find that there is a general lack of enthusiasm with our local hams when it comes to newcomers or interested prospects, so you are correct. Not much of a surprise!

I am a newcomer to the radio hobby, but it seems to me that with an army of retired hams locally, there could be some effort to push our hobby a bit and lend a hand to newcomers.

At my radio class there were only two used rigs for sale, and no accessories at all. No dealers showed up to show off new equipment or even drop off catalogs. I think that a list of used equipment could have been compiled from the local repeater or from the local ham club.

I expected a visit from the president of the local radio club to round up new members, but this opportunity was missed as well. I must admit that some members of the 2 meter club showed up and were well received, so someone is doing some thinking.

One suggestion I would make is that amateur radio students could be paired with older, more experienced hams to help them find and get their stations running. Not to mention a chance to pass on all that knowledge before it is lost to the Silent Key Patrol!

I am temporarily inactive due to an illness and financial setback that forced me to liquidate my station, but as soon as I am able, I will be back on the air. The questions still stand, though: What kind of old rig is dependable, who do I buy it from, and how do I keep it running? Better yet, who will take the time to explain?

The Simple TX TX

The perfect companion for the SupeRX receiver!

by Bruce O. Williams WA6IVC

Ever since I introduced the Simple SupeRX (see the April 1991 issue of *73*), I meet QRPers looking for a companion transmitter at every hamfest I attend. The transmitter must have 2-3 watts output, provide reasonable performance and cost, and be suitable for portable or backpacking use with the SupeRX. It must also be able to operate on any band from 80 to 20 meters. And now it exists—the Simple Texas Transmitter (TX TX). It produces 1.5-2.5 watts on any one of four bands, is simple to build, and can be put on the air in about two hours.

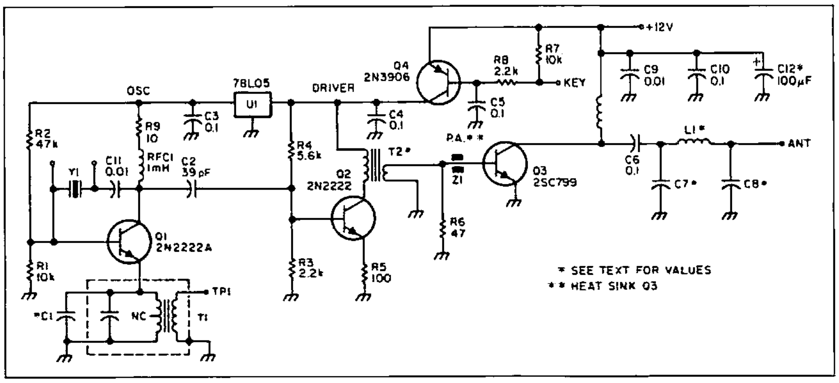

Figure 1. Schematic for the Simple TX TX.

After developing the Simple TX TX, I have a real sense of accomplishment. It only oscillates where it should, and it's not a particularly exotic design. It uses a basic oscillator/driver/amplifier scheme. There are a couple of improvements over the classic circuits, but by and large, it is a perfectly straightforward application of several proven circuits. Refer to Figure 1 for the schematic. Q1 is a bipolar-transistor Pierce crystal oscillator. A tuned output is desirable in a crystal oscillator to maximize power output and reduce harmonics. However, in the Simple TX TX, unlike most circuits, the resonant circuit, T1, is in the emitter of the transistor. This provides the necessary stability and purity of the signal I wanted.

I tried the microminiature 10.7 MHz IF transformer in the collector circuit initially, and attempted to take the oscillator output from the secondary of the transformer, but discovered that the output of the oscillator was too low, requiring an additional stage to drive the final amplifier. With the resonant circuit in the emitter, the output of the oscillator, taken at the collector, is about 4 Vpp, and it does not exhibit the distorted sine wave that many crystal oscillators do.

The oscillator collector voltage is regulated at 5 volts by U1, a subminiature 78L05 voltage regulator rated at 100 mA. Since the collector current of Q1 is only about 10 mA, there is little stress on the regulator. Keying is accomplished by controlling the 12 volt input to the regulator via Q4. This arrangement creates a smooth keying characteristic, without clicks or other problems.

Q2 is a conventional buffer/driver. The 2N2222A is capable of driving the final amplifier to about 1.5 watts with 12.0 volts, and over 2.0 watts with a 13.5 volt supply. Q2 is keyed with the oscillator by Q4. T2 is a wideband balun transformer that drives a conventional class C final amplifier, Q3. Because of the nearly pure sine wave output of the oscillator, the output from the PA is clean and free from distortion.

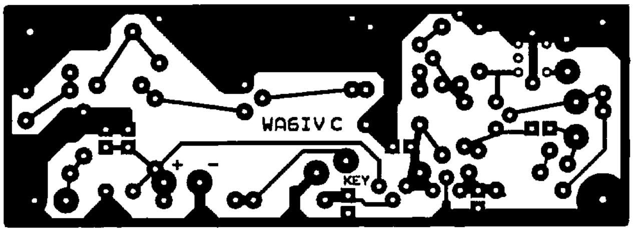

Figure 2. The PCB foil pattern.

The simple output filter (L1, C7 and C8) attenuates harmonics, but provides no impedance matching. It is taken directly from the ARRL's *Solid State Design*, a book by Wes Hayward W7ZOI and Doug DeMaw W1FB (1986). Because the output power is less than 5 watts, this filter provides sufficient filtering to meet FCC spectral purity requirements.

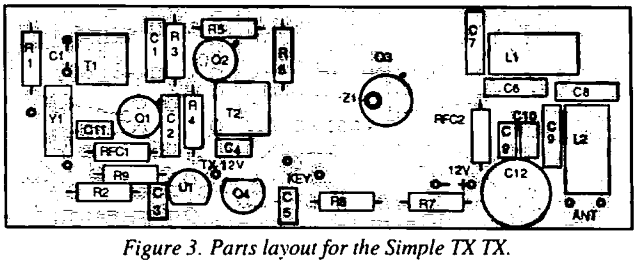

Figure 3. Parts layout for the Simple TX TX.

There are several good bipolar amplifiers available that could be used for Q3. The 2SC799 is

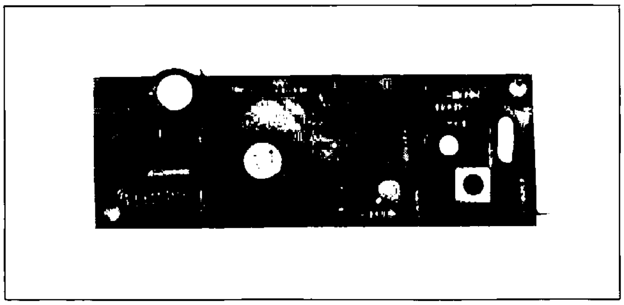

Photo. The simple TX TX.

T2 Values

Band	Primary	Secondary
80m	5 T No. 28 enam.	1 T No. 24 enam.
40m	5 T No. 28 enam.	1 T No. 24 enam.
30m	4 T No. 28 enam.	1 T No. 24 enam.
20m	3 T No. 28 enam.	1 T No. 24 enam.

Output Filter Values

Band	C7, C8	L1
80m	750 pF	21 T No. 24 on T-50-2
40m	470 pF	14 T No. 24 on T-50-2
30m	300 pF	12 T No. 24 on T-50-2
20m	210 pF	12 T No. 22 on T-50-6

readily available at low cost. It was commonly used as an output amplifier in CB rigs, and is capable of up to about 4 watts. Of course, the 2N3866, 2N4895, RCA 4013, or any of several other TO-5 configured transistors can be used. The MRF 472 and MRF 476 are also usable with a slight change in pinout.

The Simple TX TX design is very forgiving. You can substitute parts of different values for almost any of the components shown. The only critical parts are the 10.7 MHz transformer, T1, and the output filter components. I tried several different values for RFC1 and RFC2, and the effect on performance was minimal.

Construction

I built the Simple TX TX prototypes using printed stripboard (see the table for sources of parts). This product is easy to use, and not expensive. So-called "ugly construction," or what Zack Lau KH6CP/1 now calls "ground plane" construction, is another option. I personally have never had much luck with this approach, but I know of many home-brewers who do very well using this technique. However, a printed circuit board is available at a reasonable price (see the table). Figure 2 shows the etching pattern for the circuit board, and Figure 3 shows component placement. You can get a complete circuit board kit from MXM Industries. I recommend using the available printed circuit board, since it speeds construction and makes it difficult to "garf" up the circuit.

Start your construction by installing the power supply capacitors and keying circuit components, and the 5 volt regulator, U1. Don't make the mistake of attempting to complete the entire transmitter before testing the individual circuits. Build one stage and check it out before going to the next. Troubleshooting the entire transmitter will drive you nuts, and there is a strong likelihood that you will damage some of the components in the process! After assembling the regulator and keying circuit, make sure that the output of U1 is approximately 5 volts (typically 5.02 volts), and that the keying circuit operates properly. Only after this crucial step should you continue.

Install the components of the oscillator (R1, R2, R8, T1, C1, RFC1, Q1, C2) and verify that the oscillator is operational before continuing to the buffer/driver, Q2. Tune T1 for the best sounding signal, not necessarily the signal with the most output. Check that when the oscillator is keyed there are no key clicks or other anomalies during keying. You can monitor the output of the oscillator on a ham band or general coverage receiver. If you have a frequency counter or oscilloscope, a small piece of component lead can be soldered into the board at TP1 to allow confirmation of the proper signal. Don't be surprised if the frequency of oscillation is a little above the frequency indicated on the crystal (1–2 kHz). It's easy to tune the output of the oscillator to the frequency you desire later.

Extra Adjustment for 20 Meters

T1 is a microminiature (7mm) 10.7 MHz IF transformer. To make the transformer resonant on the particular band of interest, a padding capacitor must be added across the 3-pin primary. Different values for capacitor C1 for operation on the 80, 40, 30, and 20 meter bands, respectively, is given in the parts list.

Although the value for the padding capacitor is shown as 27 pF for 20 meter operation, some modification to T1 is also required. There is a small ceramic capacitor mounted in the base of the transformer. This capacitor must be *carefully* removed before you install the transformer on the circuit board.

Carefully break the capacitor in half, using a very small, sharp X-ACTO® knife, and pull the two halves out. Do not try to pull the halves from the transformer base. First, carefully cut the leads connected to the halves, then remove the halves.

Check continuity between the two outboard pins on the 3-pin side of the transformer. If there is no continuity, the transformer must be replaced. With this capacitor removed, T1 will be resonant at 20 meters with the addition of the 27 pF capacitor as C1.

The value of 39 pF for C2 limits the output of the Simple TX TX to about 1.5 watts with a 12 volt supply. If you wish to increase or decrease the output, some experimentation with C2 will be required. I found that if the value of C2 is as high as 100 pF, both Q2 and the output transistor will exhibit extreme heating, and shortly destruct! I found that the usable upper-limit value is about 51 pF.

Winding T2

T2 is a broadband transformer wound on a

Z1	FB-43-201	ferrite bead

Printed stripboard may be ordered from Dick Smith Electronics/American Electronics, P.O. Box 468, Greenwood IN 46142. (800) 872–1373.

Transformers are available from Mouser Electronics, 2401 Hwy. 287 North, Mansfield TX 76063. Tel. (817) 483–4422; (800) 346–6873.

For transistors and balun cores, you may contact Danny Stevig KA7QJY, P.O. Box 7970, Jackson WY 83001. Tel. (307) 739–1634, evenings.

A drilled and plated circuit board is available from FAR Circuits (N9ATW), 18N640 Field Court, Dundee IL 60118. Price $4.50 plus $1.50 S&H.

You may also obtain a complete circuit board kit, which includes all board-mounted components and a crystal on the QRP calling frequency for the selected band, from the author at MXM Industries, Rt. 1 Box 156C, Smithville TX 78957. Tel. (512) 237–3906. Price for the complete kit with crystal is $32.95 plus $4.00 S&H. Texas residents add sales tax.

A complete transmitter/receiver kit on a single board (uses the SupeRX receiver) is available for $79.95 + $4 shipping.

BN-43-2402 binocular balun core. I start winding T2 by putting the secondary 1-turn winding on first—1 turn of #24 enameled wire for operation on the 80, 40, 30, and 20 meter bands—then I wind the primary over the secondary.

The turns ratio for the primary winding varies with the particular band. For 80 and 40 meters, it's 5 turns of #28 enameled wire; for 30 meters, it's 4 turns of #28 enameled wire; and for 20 meters, it's 3 turns of #28 enameled wire.

The primary leads should come out of one end of the core, and the secondary leads out of the other end of the core. The balun core is extremely small, and the holes through the core are also small. If you have to use larger size wire, you may have problems getting all the turns on. You can use a larger balun core, of course, but some experimentation with turns and turn-ratios will be required. If you don't have a binocular type of core, a broadband toroidal transformer can be substituted. *Solid State Design* gives information for using toroidal cores as broadband transformers.

Output Filter

The final power amplifier, Q3, is a straightforward configuration which you may recognize as about standard for most QRP transmitters. The value of RFC2 is not very critical. I have tried values from 15 µH to 1 mH with little effect on performance. I found that the 1 mH value reduces the output a little, just because of the additional resistance of the winding in the higher value. Values from 25 to 100 µH will work fine. D1 is a 36 volt zener diode that protects Q3 from damage in the event an antenna is not connected when the transmitter is keyed.

Testing and Operation

If you have followed my suggestions about assembling each stage separately, by the time you finish construction, the transmitter will be ready to use. A few preliminary tests are a good idea, however. NEVER test the transmitter without a dummy load (of at least a 5 watt rating). If you don't have a suitable dummy load, you can construct one by placing three 150 ohm, 2 watt resistors in parallel, or by using any number of combinations. Although I have a 10–1000 watt dummy load, I generally use a small, calibrated SWR/wattmeter with a home-built dummy load. I find that my commercial dummy load/wattmeter is poorly calibrated at low power levels, showing less than a watt when the actual power is over 1 watt. One sure way to get a good estimate of output power is with an oscilloscope.

It is essential, even at low power levels, to use a heat sink on the final amplifier. In fact, it may be a good idea to put a heat sink on Q2, since it does carry a heavy burden in this design. Although during tune-up the final amplifier may seem to be running cool, when it is mounted in a cabinet, the circulation of the cooling air may be impaired. In the same vein, be sure to install a ferrite bead, Z1, on the base lead of the final amplifier.

It is possible to VXO the crystal a little by placing a capacitance across it. Don't expect too much of a shift, however. Maybe just 2–3 kHz. Remember that the tuning capacitor must be isolated from ground. I use a DPDT switch with a center OFF position, and connect the two center connections across the crystal. In the center OFF position, no capacitance appears across the crystal, and the frequency will be whatever the crystal generates. I placed two capacitors across the other two poles, so that if the switch is in one position, that capacitor controls the frequency, and if it's in the other position, the second capacitor controls the frequency. If you can't get the frequency where you want it with a fixed capacitor, there is room on the switch to mount a small variable capacitor to fine-tune it.

Good luck with your Simple TX TX! The project is so simple that you should not experience any major difficulties. If the darned thing doesn't operate right off, check your wiring for solder bridges, and see that the components are in the right place. With the Simple SupeRX, no problems have been reported to me apart from two isolated part failures not the fault of the design. If you think you have a problem that I might be able to help you with, or if you just want to talk about it, please do not hesitate to write or even call. ■

You may contact Bruce O. Williams WA6IVC at MXM Industries, Rt. 1 Box 156C, Smithville TX 78957. Please enclose an SASE.

The Ramsey 2 Meter Transceiver Kit

Build your own high-quality FM rig the easy way.

Ramsey Electronics
793 Canning Parkway
Victor NY 14564
(718) 924-4560
Price Class: FTR-146, $150; FTR-C (cabinet), $25; add $10 S&H, plus $4.50 for COD.

When Ramsey Electronics first advertised the FTR-146 2 meter transceiver kit, the promise of a synthesized VHF radio for $149 was just too attractive to pass up. My only fear was that a project this inexpensive might be difficult to construct—or not work very well. Fortunately, these fears proved unfounded.

Features

The FTR-146 is a six-channel diode-programmable PLL-synthesized FM transceiver, covering 144.000 to 147.995 MHz. "Diode-programmable synthesis" means that you select six of your favorite operating frequencies and program them into the radio when you build it. Programming is done by installing diodes in a binary matrix, a procedure that is much easier than it sounds. Transmit offsets for +600 kHz, −600 kHz, and simplex are also programmed in by installing diodes. Ramsey conveniently provides a 12-position switch with the kit, so you can add up to six additional channels by expanding upon their diode matrix.

FTR-146 RF output is rated at 4–6 watts, which is plenty of signal for base or close-in mobile operation. Since the radio draws only 1.5 amps on transmit, nearly any inexpensive CB-type supply will provide enough power.

Although amenities like a signal strength meter, microphone, and built-in speaker aren't provided with the FTR-146 kit, it does include attractive "packet-ready" features other radios may not have—like PIN-diode T/R switching and a DIN-type TNC jack on the rear panel. An on-board jumper selects squelched speaker-level audio or unsquelched discriminator-level audio for your TNC. For an additional $24.95, Ramsey offers an attractive 9″ x 6″ x 1.5″ cabinet with silk-screened front and rear panels, and matching knobs. I found plenty of room inside this enclosure to install a home-brew channel expansion board and a 3″ speaker.

Constructing the Kit

With any kit, the dividing line between success and frustration usually depends on two key factors: the integrity of the circuit board, and the clarity of the instructions. A poorly designed board or a confusing manual can turn even the simplest kit into a nightmare Happily, I found the FTR-146's CAD-designed two-sided PC board an absolute pleasure to construct. Part locations are silk-screened on the component side, and there's plenty of space for everything to fit. You won't need the dexterity of a brain surgeon to make it look professional. The same CAD program that generated the board layout was used to produce striking 11″ x 17″ multi-colored parts placement and schematic diagrams for the manual. Credit goes to project designer Tom Hodge WA2YTM for some fine computer work.

In a similar vein, I found the kit's documentation, written by Dan Onley K4ZRA, to be equally impressive. The manual has over 100 pages of information and diagrams to guide you through construction, complete with check-listed steps, mini-schematics, and parts placement figures for every stage. Even the parts list is cross-referenced to the installation steps in the manual! The instructions are not only detailed, they're educational as well. By the time I completed the project I had learned a great deal about how synthesized transceivers work.

For the most part, you won't need special tools to complete this project. However, if you make a mistake, you may need a vacuum-type desoldering tool (or a roll of Solderwick™) to remove parts from the radio's double-sided, plated-through, PC board. Radio Shack's desoldering iron (#64-2060) is inexpensive at $8.49, and does this job well. Also, tune-up requires nonmetallic tuning wands, including one with an insulated metal tip like the GC-8608 (Radio Shack Tuning Wand Set #64-2230). Finally, some of the air-wound inductors are formed on a 3/8-inch 18-TPI bolt. If you don't have one on hand, this could mean an unscheduled trip to the hardware store.

Improvements

I really enjoyed building the radio. But, before I'm accused of working for Ramsey's ad department, I'll confess to at least ONE aspect of the kit that I don't like. The solid-copper bell wire supplied for point-to-point wiring of controls and switches was hard to handle—and easy to break. I threw it away and made a color-coded harness from flexible stranded wire.

More significantly, I had to solve a couple of technical snags to get my rig on the air. Initially, the radio's squelch circuit wouldn't function properly, due to a defective IC. Ramsey helped me find the problem and promptly mailed a new chip.

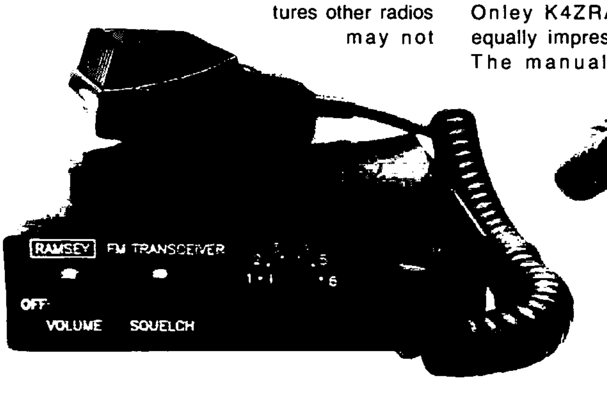

Photo A. Completed FTR-146, front panel.

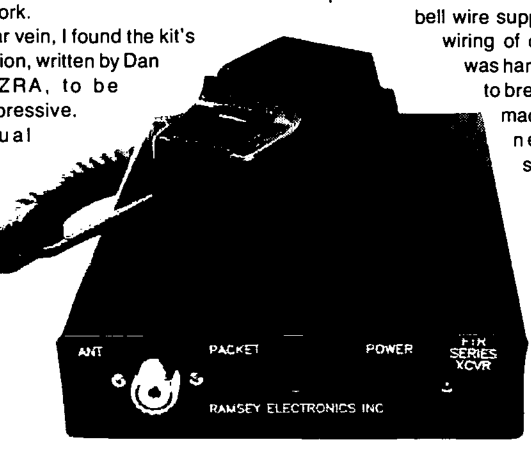

Photo B. Completed FTR-146, rear panel.

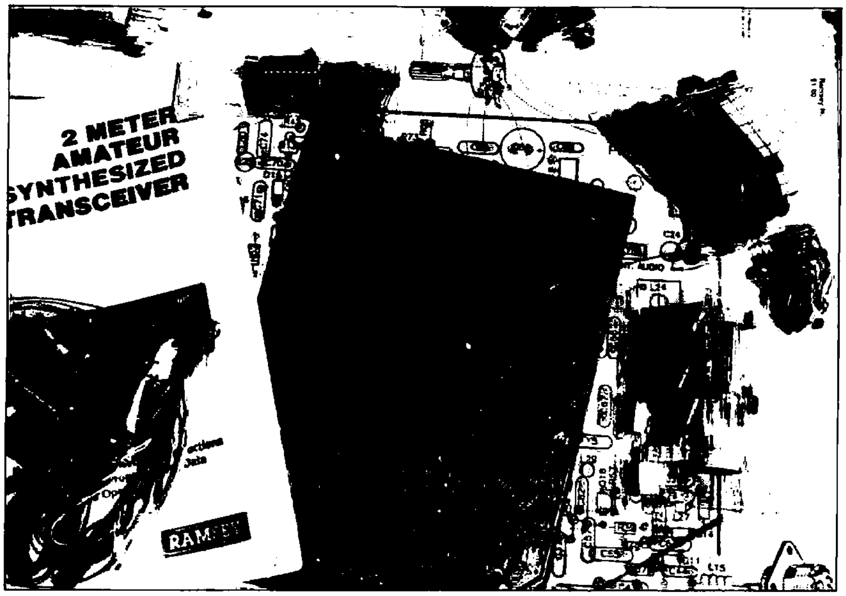

Photo C. The kit comes with a high-quality PC board, all components and excellent documentation.

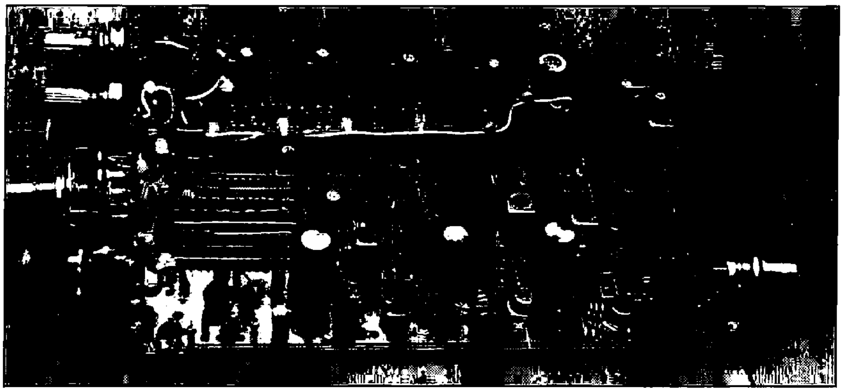

Photo D. The assembled FTR-146 transceiver board.

The second snag was a bit more complex. The radio's synthesizer IC tunes in 10 kHz steps. When a +5 kHz frequency change is needed for 15 kHz channel spacing, the loading on each mixer oscillator crystal is switched by diodes to "pull" that oscillator in frequency (recall the +5 kHz switch on your old synthesized HT). Unfortunately, I couldn't make two of the four oscillators in my radio pull far enough to hit both frequencies. I traced the problem to out-of-tolerance crystals. Once again, Ramsey helped me diagnose the problem, and promptly shipped the items I needed.

Getting on the Air

Aside from the crystal problem, alignment was straightforward. You'll need a frequency counter to set each oscillator on frequency, and an RF power meter to peak the transmitter. You'll also need a weak signal source to align the receiver. Lacking an expensive FM service generator, I terminated the antenna jack with a 47 ohm resistor and used a short scrap of wire to pick up a local repeater. Any signal weak enough to produce audible background noise will suffice.

During construction, you'll wind many of the radio's air-wound inductors by hand—a somewhat imprecise science. During tune-up, you may need to "tweak" some of these by compressing or stretching the windings (tweaking may be needed to bring a coil's associated trimmer capacitor in-range, or to optimize a circuit using a fixed capacitor). Once aligned, my radio delivered 4.5 watts into a 50 ohm load and approximated the receiver sensitivity of my ICOM HT. I later measured receiver sensitivity at a respectable 0.4 µV on an FM service monitor.

The FTR-146 microphone circuit was designed to work with an ICOM-type speaker mike, and employs "load-sensing" to activate the transmitter (there's no separate PTT line). If you opt to use a replacement-type mobile mike, you'll need to wire the PTT switch in series with the mike cartridge in order to key the radio. When I first tested my microphone, I got reports of a loud hum on the audio. I quickly discovered the cause to be stray RF pickup—a consequence of running the rig without a case into a rubber duck antenna. Connecting an external antenna cured the hum.

There are as many ways to package the FTR-146 as there are ways to use it. I keep mine next to our telephone, serving as base station for our "multi-ham" household. For this task, I installed a three-inch speaker in the Ramsey cabinet. This provides plenty of volume to hear calls while you're in another part of the house. More extensive customizing is possible—including sophisticated channel switching schemes, and even a digital display. Toward this end, manual writer Dan Onley has established a user's group and newsletter for FTR builders in order to share customizing schemes and circuit upgrades.

The Bottom Line

The Ramsey FTR-146 kit is a fine value from several standpoints. First, it's instructional. After building it I find synthesized radios less mysterious, and I'm more confident when tackling repairs on other radios.

Second, the FTR-146 is the right tool for the job. I don't really *NEED* a 50-watt radio with 100-channel scanning to hit the local repeater. The FTR-146 does this flawlessly, and people say that the Ramsey transmitter audio sounds superior to my other rigs!

Finally, for the serious packeteer, the FTR-146 may be a sensible radio to dedicate to online data communication. Hook it onto your TNC or modem and save your other rig for voice contacts.

Evolution

By the time you read this review, an enhanced version of the FTR-146 (the FX-146) will be available for $169. According to Ramsey designer Tom Hodge, this FM transceiver is now on the bench and headed for production soon. This new radio uses a more sophisticated synthesizer chip which expands receiver coverage to 20 MHz, provides a programmable offset, and facilitates producing 220 and 440 MHz versions of the radio. The new synthesizer also provides 5 kHz steps, eliminating the need to shift mixer frequencies. Other changes include a simplified receiver circuit using a more advanced IC. According to Hodge, receiver changes will provide tighter IF filtering, improved image rejection, an RSSI meter output, and enough extra board space to include a 12-channel diode matrix.

OK, so you are nervous around hot soldering irons and you have fat fingers. Should you tackle one of these kits? I say YES! Through the FTR-146, Ramsey Electronics has clearly demonstrated the ability to engineer and produce a good radio that's easy to build. And, they've shown that they can support it with first-class documentation. If my experience with the FTR-146 is any indicator, construction of the FX-146 kit should be a snap as well! I like my radio a lot, and I suspect that Ramsey transceivers are going to be with us for a long time to come. 73

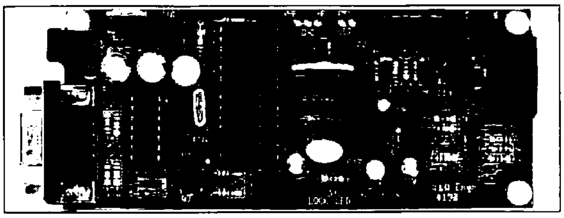
The BayCom Packet System

Run packet without a TNC.

A & A Engineering
2521 W. LaPalma #K
Anaheim CA 92801
Telephone: (714) 952-2114, FAX: (714) 952-3280
Price class: Blank board, $13; complete kit, $60; assembled and tested board, $90.



The A & A Engineering modem for the BayCom packet program.

Over the course of the last seven years packet radio has developed into amateur radio's fastest growing mode. The computer hackers love it, some operators find it useful for obtaining the latest information on a variety of subjects from ham radio to amateur astronomy, and other operators find that packet is not their "cup of tea." One thing stands incontestable, however: Packet has become prevalent in virtually all aspects of our hobby. Visit any reasonably large city, tune around 144.91–145.09 MHz, and the sound of various packet networks will greet you. Tune the HF bands near the domain of what used to be our primary digital mode (RTTY), and again the sound of 300 baud packet bursts will be heard. Virtually all of the new amateur satellites use packet as the communications medium. Most importantly, packet has given the amateur community visibility and recognition by advancing the state of the art in digital communications.

One of the main reasons for packet radio's skyrocketing popularity is its ease of implementation. Only a few years ago getting on packet meant building a terminal node controller (TNC) from a kit and interfacing it to one of the many then nonstandard computers. To those with computer expertise, this was a challenge that was eagerly anticipated. To others with a curiosity about this new mode, but who were somewhat less endowed with "computer smarts," this challenge turned into a fiasco.

Differences in standards, such as TTL vs. RS-232, resulted in damaged equipment and hurt pride. Luckily, the manufacturers of packet systems took note. Soon, factory-built TNCs were on the market with documentation that made computer and radio interfacing less of an arduous task. Each year, as the state of the art progressed, the TNCs became more capable. As of this writing, most TNCs are effectively multimode controllers that offer a diverse mix of digital modes from packet to SSTV in a single turnkey package. "Plug and play" has become the watchword.

With the present simplicity of packet radio, I found it puzzling that it wasn't being used in portable applications or public service more frequently. In October of 1989 I put together a portable packet system. It consisted of an old 2 meter handie talkie, a standard packet TNC, a Tandy LT-1400 laptop computer, and all necessary cabling. I packed all this into my attache case and headed into the wilderness for my first QRP, portable packet operation (actually the "wilderness" was a hotel room on a business trip).

Upon arrival, I set everything up and found some problems. Packet requires virtually full quieting signals with no interference. The HT with its rubber ducky antenna had to be moved a considerable distance from the TNC to avoid RFI. Even using an external antenna, I couldn't move it far enough from the TNC in the confines of the hotel room to eliminate all RFI. RF from the HT would also get into the TNC, sometimes causing it to lock up. Finally, it seemed that interconnecting the TNC to the computer really enhanced the RFI problems. I used shielded cable, ferrite forms, and all the suggested solutions, to no avail. It seemed that portable packet required a "fixed" antenna located at least 30 feet from the TNC and computer.

Get Rid of the TNC!

Commodore 64 users have a system of "TNC-less" packet, known as DigiCom>64, which has been in existence for several years.

The function of the TNC has been implemented in the Commodore's software. Even through this eliminates the TNC from the RFI equation, another problem is presented. The Commodore 64 and its separate disk drive was originally designed for 120 VAC operation. It can be modified for 12 VDC operation and through use of A & A's DigiCart>64 cartridge the disk drive can be eliminated. However, the "64" still requires an external monitor, generally a TV set. Operators have used this system successfully in portable packet radio, but if there was a way to do the same thing with the IBM-compatible laptop then portable operation is a whole lot easier.

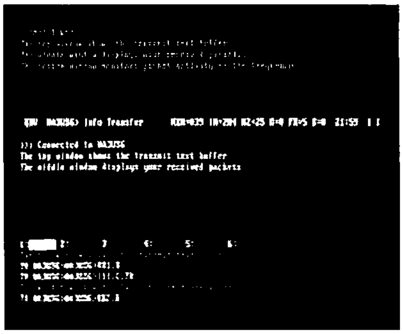
Enter the BayCom TNC-Less Packet System!

Florian Radher DL8MBT and Johannes Kneip DG3RBU of Regensburg, Munich, Germany have developed a program to allow most IBM compatibles to run packet radio without a TNC. Their system really consists of two parts: a shareware program called "BayCom," and a simple modem. The program is available from several sources, including A & A Engineering and many telephone BBS systems, such as CompuServe. Although you can completely home-brew a modem, a new kit which includes HF packet is available from A & A Engineering.

The A & A Engineering Modem

The A & A modem uses the 7910 "World Modem Chip," and is quite easy to build. It came with a high-quality printed circuit board and all the components, and took a total of just two hours to build. It is quite small (approximately 1.5" x 2.5"). Connectors are supplied to interface with the computer (DB9) and the radio (5-pin DIN).

Another nice feature is movable jumpers that allow the push-to-talk (PTT) configuration to be switched from the standard "grounded pin" to various "handie talkie" systems. By simply moving two jumpers and changing a cable, either conventional FM radios or HTs may be used. The PTT function is performed via a relay on the modem board.



The terminal screen for the BayCom packet program. Three window area display transmitted packets, received packets and monitored packets.

The only adjustment on the modem is the transmit audio level. The modem draws about 100 mA from a 12 VDC input. A & A includes a small 12 VDC wall type plug-in power supply with the modem. I found that the 5-volt regulator (7805) ran quite warm. I added a small heat sink on the regulator to keep it cooler.

The only other control on the modem is a switch that selects normal VHF operation, enhanced VHF operation, or HF packet operation. On VHF FM I noticed no difference between the "normal" or "enhanced" mode—both worked quite well. It should be noted that the modem effectively has an "audio" DCD.

Whenever the squelch is broken (by noise as well as by bona fide packets) the DCD light comes on. This causes no problem on FM packet, but on HF SSB noise and static crashes will generate a false DCD. A very nice feature of this modem is its capability to function on HF packet. It's helpful to use an external tuning indicator on HF since the DCD LED on the modem is responsive to any audio. I paralleled the BayCom modem with my AEA PM-1 packet modem (which has a tuning indicator). HF operation with the BayCom system is possible, but any noise or QRM on the frequency degrades its performance. This problem is typical with every HF packet system, however. Finally the A & A modem incorporates a 45 second 'watchdog timer' to prevent QRMing the frequency if there is a malfunction or problem with the computer or modem.

The Program (BayCom Version 1.2)

The Terminal/TNC emulation program is superb! There is a configuration file called "BAYCOM.INI" that must be initialized with your parameters (e.g.: COM port number, callsign, CTEXT, TXD, etc). Most parameters will be instantly recognizable to those with experience in conventional TNCs. Screen colors and screen layout may be modified. Up to nine simultaneous connect channels are supported.

Once the configuration file is set up and the program is booted, the terminal screen will be displayed. This screen consists of three sections: a transmit window, a receive window, and a monitor window. The transmit (or top) window holds data from the keyboard or the file that is to be sent. The receive (or center) window displays data from the station that you are connected to. The monitor (or lower) window displays both transmit and received data, along with the status of the packet, or any system requests (e.g.: connect request) as well as all packet activity on the frequency. The size of each of these windows may be changed to make that window the predominant one. By using the appropriate function key, the cursor may be placed in any window and the window contents scrolled back a number of lines (scroll back buffer size specified in BAYCOM.INI).

Since the computer is essentially the TNC, many parameters not available with conventional packet systems are displayed. The upper window status line contains the operational mode, callsign with SSID, present port state (disconnected, info transfer, frame reject, waiting acknowledge, reject sent).

Another very useful parameter that is displayed is the number of outstanding unacknowledged packets, along with the maximum number allowed. This is valuable information to have on a busy channel. Once the number of outstanding packets reaches the maximum allowed, an automatic disconnect will take place. Monitoring these parameters will flag you to stop generating additional packets until some of the outstanding ones are acknowledged.

Other displayed parameters are memory buffer sizes, Frack time, channel number, connected callsign, time from your system clock, and Com port number.

There is an excellent help screen available via one keystroke. The program has a self-connect mode that can be used without a modem. Issuing a connect request to your own callsign will cause BayCom to connect to yourself. Many aspects of the program may then be tested, exercised, and practiced. Going back and forth between the program and the help screen will help you become an "experienced user" in a matter of an hour or so.

BayCom has the capability to transfer both ASCII and binary files (binary to other BayCom systems). It offers extensive file handling utilities in the form of its diverse command set. Files may be created and edited offline without leaving the BayCom program. Most TNC monitoring functions are supported (e.g. Monitor Heard), as well as functions such as digipeating. Even the connect and disconnect sequences are enhanced with "spiffy" sound effects. For a pure packet terminal program, this is the best that I have ever seen. . . and you don't need a TNC! On an even more positive note, I could detect NO RFI FROM THIS SYSTEM in my radio!

Suggested Improvements

The only real problem that I could find was with the documentation. This consists of an ASCII file on the BayCom system disk. Simply copied to the printer, it generates a complete 49-page users' manual with a table of contents and index. While it contains a wealth of information, its translation from German is, at times, confusing.

Some of the result and error messages generated by BayCom are in German, although these will be changed to English in the near future. While this causes no problems, it is a bit startling. Finally, the modem section in the users' manual is apparently written for a different modem than the one provided in kit form by A & A Engineering. However, if you do purchase the A & A kit, it is "plug and play." The documentation provided by A & A is quite good and it identifies all necessary pin-outs to get both the computer and radio interfaced correctly.

In Summary

BayCom is an absolutely superb system! It is simple to learn and use. It is second to none for portable operations, and should be quite useful in public service and emergency communications. 73

Project Inspire: A VLF Space Shuttle Experiment

Build a simple receiver to explore the wonders of the 60,000 meter band!

by Jim Ericson KG6EK

Tired of hearing the same old stuff on your radio? Do you tend to think of 160 meters as the "bottom of the band"? This article will discuss both man-made and natural radio activity between 100 Hz and 10 kHz, the absolute bottom end of the VLF (Very Low Frequency) spectrum. If we call 5 kHz the center of the band, we're talking about a 60,000 meter wavelength! I will describe a simple and inexpensive (under $40) VLF receiver design, and present some ideas on how you can participate with space scientists in scientific data gathering involving VLF propagation (and possibly share some of your ham radio expertise with U.S. high school students and other experimenters) during a March 1992 space shuttle experiment. Letters inviting participation in the listening experiment have already gone out to 10,000 high school physics classes in the U.S., and both amateurs and private experimenters are also being invited to participate.

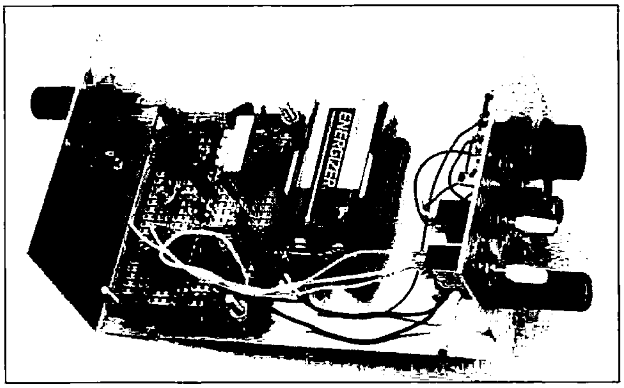

Photo A. The RS-4 VLF receiver layout, using perfboard construction technique. (Photo by Mike Mideke WB6EER.)

A Quick History

The story begins in World War I Europe, where both sides used telephones for trench communications. Soon the vacuum tube came along, opening the way for high gain amplification. Each side began intercepting "leakage" from the other's telephone communications by using amplifiers connected to widely separated ground rods. Electronic Counter Measures were born! Evidently this system worked quite well most of the time, but now and then strange falling notes filled the monitors' headsets, sounding like phantom shells passing overhead.

German scientist H. Barkhausen was assigned to fix this interference problem. He was unsuccessful, but he became intrigued by the mystery. He and other researchers picked at it for years, and by the late 1920s there was general agreement that lightning was responsible for these "whistlers." But it was not until the 1950s that the exact mechanism was found.

As researchers learned, lightning is an enormous spark discharge which produces a broad spectrum of radio energy in which all frequencies appear at once, from hundreds of hertz through hundreds of MHz. However, scientists discovered that a large percentage of lightning's effective radio energy is concentrated in the 1 to 20 kHz region, loosely defined as VLF.

VLF Punches Through the Ionosphere!

VLF static bursts caused by lightning propagate with great efficiency in the waveguide formed by the earth's surface and the lower regions of the ionosphere. Mostly it sounds just like the static you hear on an AM radio receiver. But if you listen closely, you'll sometimes find that somewhere below 10 kHz the static crackles become liquid "pings" or "whistles"...brief musical notes.

Today, the mechanism for this effect is well understood. Radio signals propagating through a non-vacuum medium become dispersed. This means that the higher frequencies travel a little faster than the lower frequencies. A lightning burst starts out as all frequencies at once and propagation in the earth-ionosphere waveguide effectively spreads the frequency components to produce audible "pings" at the lowest frequencies. By measuring this dispersion, investigators can calculate just how far the signals have traveled.

Early investigators were puzzled by the fact that nobody could find signal paths on earth that were anywhere near long enough to account for the huge amount of dispersion heard in long whistles. Eventually, new techniques including spectrum analysis helped to unravel the mysteries of whistlers. L.R.O. Storey of Cambridge University and R.A. Helliwell of Stanford University were among the widespread group which developed a new view of the earth's near-space environment, opening up the field of magnetospheric physics. As it turned out, the long dispersive whistler paths were ducts in the magnetospheric plasma which extend between the Northern and the Southern Hemispheres. These ducts (sort of like the lines you see when you sprinkle iron fillings over a bar magnet) arch to a maximum distance of several earth radii, far beyond the boundaries of our ionosphere. This explains why some whistlers have a duration of several seconds when heard here on earth.

The Antarctic Antenna Farm

In the 1950s, researchers discovered that CW transmissions from military VLF stations sometimes triggered whistler-like events. In the 1960s, they chose Antarctica as a perfect spot for controlled whistler research. Plenty of room to put up a 40 kilometer (26 mile) VLF dipole transmitting antenna, mile-thick ice (a nice insulator to keep the antenna off the "ground," and almost no interference from AC power!

A powerful transmitter was built at Siple Station, Antarctica. In the 1970s and '80s, transmissions from Siple generated a variety

of magnetospheric signals which were recorded by a monitoring station at the magnetic conjugate region near Roberval, Quebec, and by a variety of satellite monitors. These experiments have advanced scientists' understanding of the ionosphere and magnetosphere while suggesting many subjects for further research.

The Need for More Ears

Until recently, VLF research was carried out using only a handful of listening stations manned by the government and a few universities. In 1989, high school and amateur listening participation was invited in a joint NASA/Soviet experiment involving the Soviet satellite *ACTIVE*. The Soviet satellite attempted artificial stimulation of the magnetosphere by passing large 10.5 kHz currents through a 20-meter-diameter loop antenna. Unfortunately, the loop apparently deployed in a twisted configuration, and the SWR was very high. Several months of monitoring by NASA, Soviet observers, and dozens of private experimenters in the U.S. failed to produce any copy. These joint experiments were nonetheless successful in that they provided the first occasion for participation by amateurs and high school groups. The possibilities of a large network of coordinated monitors had never before been explored.

INSPIRE 1992

INSPIRE stands for Interactive NASA Space Physics Ionosphere Experiments. The private industry sponsors who, at this time, are coordinating with NASA include TRW Systems and Micro Power Systems in California, and MESA Art and Printing in Arizona. In March 1992, NASA plans to launch the space shuttle (STS-45) with the first mission in a series of 10 flights called ATLAS (ATmospheric Laboratory for Applications and Science). *[Ed. Note: STS-45 will also be the next SAREX flight.]* One of the ATLAS investigations is called SEPAC (Space Experiments with Particle ACcelerators), which is an experiment involving the earth's atmosphere, ionosphere, and magnetosphere. The 7 kW SEPAC accelerator (see Photo A) will emit a beam of electrons modulated by a series of audio tones from 50 Hz to 7 kHz. A unique feature of the transmitter is that it does not directly utilize a metallic antenna. The modulated electron beam projected into space will become its own "virtual" antenna!

SEPAC will use coordinated high school and amateur experimenter teams to listen and tape record the radio waves. The locations where the transmissions can be detected will define the "footprint" of the signal, an impossible task without a large number of participants.

How to Hear Audio Frequency "Radio" Waves

Radio signals in the VLF region occur at frequencies ranging from a few hundred hertz to something above 10 kHz. These frequencies are readily accessible to human hearing but, even so, they are not directly audible. Why? Because they are electromagnetic events which do not produce the mechanical vibrations in the air that our ears need to detect them as sound.

In order to hear these waves, we must convert their electromagnetic activity to acoustical vibration. Conversion is done with a transducer—a simple amplifier connected to a loudspeaker or headphones—that uses the electrical energy to move air molecules to produce an audible sound.

Building a Practical VLF Receiver

It is fortunate that very simple and inexpensive circuits can be used to hear and record both natural and man-made VLF signals. Beginners can build them; it is not necessary to understand the theory of operation in order to make equipment that works very well.

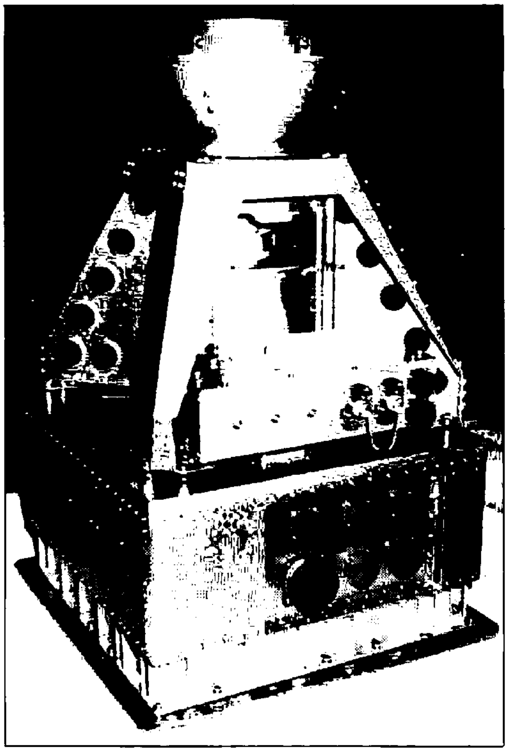

Photo B. The "business end" of the SEPAC Electron Beam Generator. The 7.5 kW electron beam is emitted from the cone at the top. The base (measuring about two feet on a side) is a large heat sink. Peripheral drivers and associated electronics are in a separate module. This experimental package will be mounted on a pallet in the cargo bay of the shuttle. (Photo courtesy of TRW.)

The receiver described here has been dubbed the RS-4 by its designer, amateur experimenter Michael Mideke WB6EER. The identical design (in kit form) will be constructed and used by the participating high school physics classes. All essential components are listed in the current Radio Shack catalog.

The receiver uses a FET input stage to transform the extremely high impedance of a short (1 to 10 foot) antenna to a more practical value. A low-pass filter rolls off frequencies above 7 kHz in order to prevent overloading from high power OMEGA radio-navigational signals at 10.2 kHz and above. The active high-pass filter (controlled by SW-1) significantly rolls off frequencies below 1 kHz, helping to reduce the hum from 60 Hz power line harmonics. A ferrite bead (Amidon FB901-43, available from Amidon Associates, 12033 Otsego Street, North Hollywood CA 91607) in the FET gate circuit helps prevent overloading by radar and TV. Resistor R1 should be shorted via SW-3 when using an antenna longer than about 30 feet. A switch and jack are included to allow the operator to use a microphone for insertion of time marks and commentary while recording.

Note that the receiver uses a jack instead of a conventional power switch. Inserting a shorted plug into the power jack completes the battery negative circuit, applying power to the unit. This approach prevents accidental turn-on of the receiver while it is being transported. (There is nothing more frustrating than pulling the receiver out of your knapsack to discover that it has gotten turned on and the battery is dead!) *[Ed. Note: You can use an SPST switch in place of the jack if you so desire.]*

The layout of the circuit board is not particularly critical (see the accompanying photo for suggested layout using perfboard construction). Try to keep "output stuff" as far as possible from the antenna input. Component values aren't critical either, but try to keep the 11k and 22k resistors associated with U1-A within 5% or so. Since Radio Shack doesn't supply 11k resistors, you can parallel two 22k units, or series-connect a 10k with a 1k.

When all components (including jacks and switches) are soldered in place, it is a good idea to double-check the wiring and do some preliminary tests before mounting the board in the enclosure. The first check is to remove U1 and connect the 9V battery to the circuit, in series with a milliammeter. It should read about 0.5 mA. If the meter indicates much more, or no current at all, something is wrong. Go back and check your work.

The second test is to disconnect the power and insert U-1 in its socket (check for proper orientation). When you reconnect the battery, current consumption should be 3 to 6 mA. If it is, chances are good that everything is OK.

When the receiver is completed, raise the whip antenna a few inches and attach a ground (or several feet of wire if no ground is handy). Listen with Walkman-type headphones or a monitor amplifier, and verify that you have hum and noise. Touching the small antenna, or even moving your hand near it should increase the hum intensity. Switching the high-pass filter in and out should make a noticeable change in the sound of the output. The series antenna resistor will make little difference, whether it's in or out.

Using the Receiver

Even though high-pass filtering is incorporated in the receiver design, it is not a cure-all for the pervasive hum radiated by the AC power lines that dominate our modern civilization. To get reasonable reception of VLF signals, you're going to need to find a site which is at least 500 meters from AC power lines. You'll also need some kind of ground or counterpoise. Usually a simple one-foot nail or spike provides enough grounding to prevent squeals in the receiver. The chassis of an automobile (engine off!) also works nicely. Try the little Radio Shack whip antenna if you are in the open, and maybe a 20- to 50-foot wire if you're in the woods. You will hear some AC line hum, but if you've picked the right site you'll also hear clicks, pops and, with some patience, some whistlers!

Alternatives to Building RS-4 from Scratch

The volunteer nonprofit INSPIRE organization is offering the RS-4 receiver in kit form to the high schools, and the same deal is available to radio amateurs and private experimenters. At $49.95 postpaid (plus $4.12 sales tax in CA), the kit includes:

- All components, enclosure, etched PC board, and detailed assembly instructions.
- *The Beginner's Guide to Whistler Hunting*, by Michael Mideke WB6EER, a 23-page history of VLF, including tips and advice on observing, describing, and recording natural and man-made signals at very low frequencies.
- A 60-minute narrated cassette tape by Mideke which samples the incredible variety of sounds that can be heard in the VLF range. Included are notes describing the audio segments, and sample spectograms of some of the signals.
- Instructional materials designed to assist you in working with high school students to mutually learn more about natural radio and the ATLAS-SEPAC INSPIRE mission.
- You will also receive updates by mail about SEPAC operation schedules, and the status of the mission.

To order an INSPIRE kit, send a check made out to INSPIRE to: Bill Pine, Science Department, Chaffey High School, 1245 N. Euclid Avenue, Ontario CA 91762. If you need a receipt, or have any questions, please include an SASE. If you just want the blank PC board, it's available for $7.

If you decide to build the RS-4 as described in this article, but don't anticipate direct project participation, you may still want to get a copy of the Mideke booklet and audio tape. The Guide is $6 postpaid in the U.S. (plus 83¢ sales tax in CA), $12.50 outside North America. Write Michael Mideke at P.O. Box 123, San Simeon CA 93452-0123.

For those not interested in construction but who would like to experiment with a receiver, Conversion Research has a new VLF pocket receiver available completely assembled for $48 postpaid in the U.S. (plus $3.96 sales tax in CA). The circuit is not exactly the same as the RS-4, but it is fully effective, includes a 33-inch telescoping whip antenna and a battery, and is housed in a sturdy diecast aluminum enclosure with an on/off

Why buy a TNC?

PC HF FAX + PC SWL $119

SPECIAL COMBINATION OFFER

For a limited time, if you order PC HF FAX $99 (see our other ad in this issue), you can add PC SWL for only $20 instead of our regular low price of $99.00.

PC SWL contains the hardware, software, instructions and frequency lists needed to allow you to receive a vast variety of digital broadcasts transmitted over shortwave radio. All you need is any IBM PC or compatible computer and an SSB shortwave receiver. The product consists of:

Demodulator
Digital Signal Processing Software
80 Page Tutorial Reference Manual
World Press Frequency List
Tutorial Audio Cassette with Samples

PC SWL automatically decodes Morse code, Radio Teletype, FEC (forward error correcting code), SELCAL (selective calling transmissions), and NAVTEX.

PC SWL lets you tune in on world press services with up to the minute news, meteorological broadcasts, ham radio operators, coastal shore stations, aviation telex and much more digital action on the shortwave bands. Find all the utility station action you have been missing. PC SWL software uses the processor in your PC to do the work, why pay for another expensive box when a simple interface and your PC and do the job?

ADVANCED FEATURES:

Tuning Oscilloscope
Digital Waveform Presentations
Auto Calibration and Code Recognition
Continuously Tunable Filter Frequencies
Variable Shift
Adjustable CW Filter Sensitivity
Unattended Capture and Printing

switch, audio gain control, and a 3.5mm jack for stereo earphones. Order from Conversion Research (Frank Cathell K3YAZ), P.O. Box 535, Descanso CA 91916.

Project INSPIRE offers an opportunity for amateurs to be involved in a truly significant research project. To make it fully effective, we amateurs need to bridge the gap between the NASA shuttle experiment and local high schools. Pick up the phone and connect with the physics teacher at your neighborhood high school. If he (or she) hasn't heard about INSPIRE, have them send an SASE to Bill Pine for information. Offer to help students build the kit, and maybe give some advice and assistance in searching out a remote and radio-quiet listening site for the March 1992 mission. Good hunting on 60,000 meters! 73

ZD Engineering Hardline Matching Transformers

ZD Engineering
605 Balsley Avenue
Findlay OH 45840
Tel. (419) 424–8765.
Price Class: $28–$30 per pair (available for any band between 144 and 1296 MHz). Other frequencies can be specially ordered—call for price quote. Two-port power divider—$40 including companion transformer.

'A great way to use all of that cheap CATV cable!

Ham radio operators, in general, are a resourceful bunch. Most hams have some experience with making something out of nothing, and just about every amateur product advertised makes you say, "Why didn't I think of that??" The RF hardline matching transformers manufactured by ZD Engineering are just such an item. Not only do these matching transformers allow the use of very cheap CATV coax for ham radio, they also perform environmental and social services as well.

What's So Good About Hardline?

If you're new to ham radio, all of this interest in hardline may be somewhat confusing. After all, why deal with big holes in the wall and stiff, uncooperative cable, when a piece of RG-8 or RG-58 does the same job? The answer is cable loss.

Cable loss refers to the amount of power that is lost on the trip from the transmitter to the antenna. It varies from cable to cable. A percentage of your transmitter power is used up on the way to the antenna due to cable resistance and other factors. This "missing" power is turned into heat which dissipates along the cable rather than being radiated from the antenna.

As you might guess, cable loss increases as the cable gets smaller, and as the frequency gets higher. It also increases as the VSWR increases, which means that you lose even more power in the coax if the antenna isn't properly matched. Loss isn't much of a problem on the HF bands, but on VHF and above, it's a real concern.

For Example...

Consider a 2 meter transmitter feeding an antenna on a tower, with a coaxial cable length of 100 feet. An average loss factor for 100 feet of RG-8/U at 146 MHz might be 3.5 dB. A 100 ft. piece of 7/8" hardline has a loss factor of about 0.6 dB—a difference of almost 3 dB. What this means in terms of performance is that the same difference in radiated signal can be realized by either doubling your transmitter power—or by switching to hardline. (While different varieties of cable have different loss factors, the values presented here represent reasonable averages.)

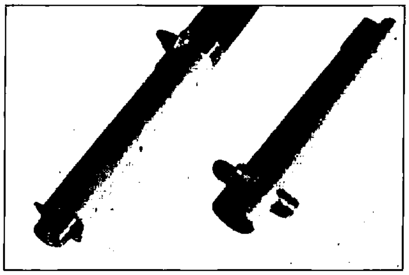

Photo A. 440 MHz Matching Transformer attached to 7/8" line, shown next to 440 MHz power divider.

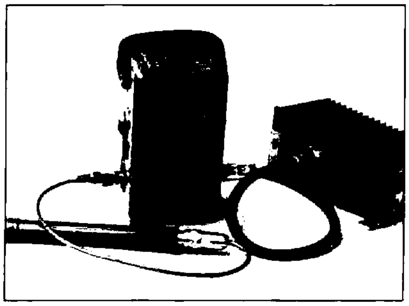

Photo B. 440 MHz Matching Transformer terminated in a 50 ohm dummy load.

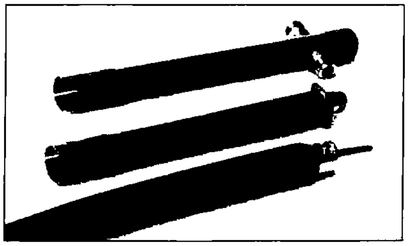

Photo C. 7/8" line prepared for installation of matching transformer and power divider.

If hardline is such great stuff, why isn't everyone using it? As usual, the answer is money! Prices vary, but a good estimate of communications grade hardline, in amateur quantities, is right around "several bucks a foot." Yikes! Not only that, but even if you can get the line for free, the connector prices are prohibitive.

As luck would have it, there is one source of free (or nearly free) hardline. The type of cable used for main runs by CATV companies turns out to be a very high grade of hardline, and it comes in 1/2", 3/4", and 7/8" inch sizes. These cables typically run for miles, and a "short end" to a cable company is often anything less than 500 feet. These "short ends" are often available for the asking—nice long sections of low-loss hardline—just haul them away. But there is one problem—it's 75 ohm impedance cable. And then, you still need to buy those expensive connectors.

The Solution

Fully aware of all of the above facts, the folks at ZD Engineering put two and two together and came up with six. The ZD Engineering Hardline Matching Transformers allow the use of standard CATV hardline for communications use. Each adapter consists of an appropriate connector (UHF or N) and a quarter-wave matching section that mounts on the end of the hardline.

A pair of matching transformers turns a piece of hardline into a flat 50 ohm transmission line (for only $30). It may seem like magic, but the ZD Adapter impedance transformer trick is based on straightforward transmission line theory. One characteristic of a quarter-wave section of transmission line is that it has the ability to match two unequal impedances provided that the impedance of the quarter-wave matching section is of a specific value. The value happens to be the square root of the

CIRCLE 270 ON READER SERVICE CARD

product of the two values to be matched—in our case, 50 and 75 ohms.

The value of the matching section therefore needs to be 61.2 ohms. The ZD Hardline Adapter is simply a quarter-wavelength line, built to the size necessary to produce a 61.2 ohm impedance. The line is then machined to allow mounting to the desired size of hardline, and a connector is silver-soldered to the other end. Although straightforward in design, the adapters provide a feature that makes installation a snap, and prevents a problem that's often experienced with lines of this type.

One of the main difficulties experienced with long runs of CATV hardline has to do with the amount of expansion and contraction that the copper-coated aluminum center conductor undergoes with changes in temperature. Expansion can cause the center conductor to move within the coax, stressing the connections. In extreme cases, the contraction of the center conductor will be so great that it will recede back into the dielectric by several inches.

The ZD Hardline Transformers eliminate this problem by providing a receptacle that's machined to allow the insertion of several inches of center conductor (in the 146 MHz version, the center conductor could be left up to two feet long). This extra length of conductor means that the connection will be making contact regardless of thermal expansion or physical movement.

The coax is simply slid into the adapter, and the inner receptacle holds the center conductor firmly in place. The outer conductor of the adapter is then clamped to the shield of the coax, holding the whole assembly in place. No soldering, threading, or special tools. The ZD Adapters come with explicit installation instructions, and a small amount of anti-oxidizing compound is included in the hardware package.

Transformers are available for 144 MHz, 222 MHz, 440 MHz, 903 MHz, and 1296 MHz. In addition, straight connectors (with no matching section) are available, as are power dividers.

But Do They Work?

The proof of the pudding is in the transmitting, and in this case the ZD Transformers worked just as expected. A series of tests was run using both 7/8" and 1/2" line, at power levels of 10 and 100 watts.

In all cases the measured loss was exactly what was expected from the coax itself—the transformers introduced negligible, if any, additional loss. (See the Table for typical hardline loss figures.) In addition, the transformers produced an absolute flat match into a 50 ohm dummy load. (Due to their high quality construction, the quarter-wave sections probably have a lower loss factor than the cable itself.)

Installation Tips

At this point, it may seem like the ZD Transformers are almost too good to be true. There are a couple of slight limitations that should be noted. First, the physical construction of the adapters could allow water to infiltrate under the outer cable jacket if proper waterproofing methods aren't taken. This can obviously be prevented by the careful use of Coax Seal™. The instructions that come along with the ZD Transformers state that you should wrap Coax Seal so that it overlaps two inches on each side of the junction of the transformer and the hardline. You should make sure the clamp is covered completely by sealant as well.

Second, the length of the adapter is rather long compared to the length of the section of coax that the adapter clamps onto, especially in the 2 meter version. This means that any movement of the adapter will be felt at the cable junction with a fair amount of leverage.

The adapters and the cable should be physically secured to a solid structure (the tower leg or, if indoors, a wall) to keep them from moving, and flexible coax jumpers should make the final connections to the antenna or transmitter. This is common practice in the commercial radio field, but may be something new to some amateurs.

Obviously, these two points are a minor trade-off in order to obtain a piece of low-loss line, but they should be carefully addressed. (The loss factor of hardline increases dramatically if the line is filled with water!)

Saving the Earth

Skeptical by nature, the author decided to check out the claims of all this low cost hardline available at cable TV companies. Obviously, the true value of a product like the ZD Transformer is directly related to how cheaply one can get the hardline. After calls to three cable companies in the area, it was clear that the term "low cost hardline" was something of a misnomer.

More correctly, it should be called "Free—how much do you want?" or perhaps, "We'll give you a few bucks to haul it away" hardline. Environmental awareness, landfill problems, and recycling have finally caught up with the CATV companies. Those "short ends" we were discussing earlier have to go someplace, and the landfill doesn't want to deal with them.

Aluminum scrap collectors used to burn the jacket off and salvage the metal, but burning the cable produces toxic gases—no longer an option. In most cases the short ends and old replaced cable are thrown in a pile, and someone who specializes in scrap cable comes by once a year—and *charges* to haul it away.

One CATV manager proudly told of a deal he worked with a scrap dealer concerning a run of existing cable that was being replaced. After a day on the phone, he finally found someone who would come and get the TWELVE MILES of old 7/8" cable and haul it away in exchange for the aluminum value—a real coup.

Obviously, the cable companies want to get rid of this stuff. Not only are you going to set yourself up with a very low loss antenna line system, saving a load of money in the bargain, you're also doing the Earth a favor. And the social implications? Just think how happy things will be around the house—once you tell the XYL how you saved a thousand dollars on hardline by using ZD Matching Transformers, and then only spent five hundred dollars on a new rig.

Now why didn't I think of that? 73

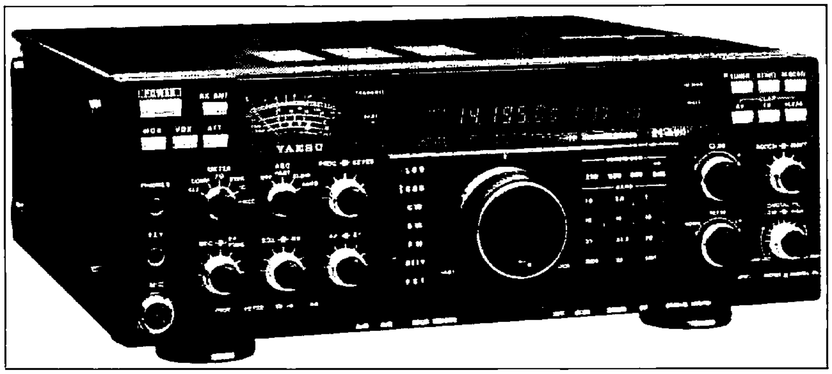
The Yaesu FT-990

A fully-equipped transceiver for the everyday ham.

Yaesu USA
17210 Edwards Road
Cerritos CA 90701
(213) 404-2700
Price Class: $2,400

The FT-990 is advertised as incorporating many of the features found on the FT-1000, yet leaving out some that most hams would seldom use. The result is a fully-equipped transceiver somewhat more affordable than the FT-1000, and more applicable to the typical ham. (See the sidebar for a list of some of the FT-990's features.)



The Yaesu FT-990 HF transceiver.

Operating

Getting the FT-990 on the air was straightforward and took just a few minutes. Only two things are required to operate the rig: AC power and an antenna. This is a complete HF ham station in a single box.

If you are just entering the microprocessor rig era you may find the large number of controls rather formidable, but don't be daunted. The FT-990 is really a very simple rig to operate and the dexterity it offers will be warming to any operator. Most functions are selected via microprocessor control buttons, in contrast to the old wafer switches of yesteryear with their thump-and-bump knobs.

Frequency selection is done with the main tuning knob, which has a very heavy, yet smooth feel. Actually, this can be said for all the controls on the front panel. They operate smoothly and are good-looking. Keypad selection of frequency is simple (except for adding a leading zero below 10 MHz) and, after the memories have been set, selection can be made directly from the memories. There are 90 memories, all tunable and scannable. Of course, there are two VFOs. The frequency readout is excellent and the display also monitors mode, memory number, VFO in use, tuning speed, and clarifier offset (RIT).

The automatic antenna tuner does its work quickly, even when not operating from one of its 39 memories. Typically, it only takes a few seconds. The received audio is a little mushy, to my ears, when all controls are open or centered, but slight adjustments to the DIGITAL FILTER and SHIFT controls make it real sharp (more about these features later). My transmitted audio got many unsolicited reports of "audio really sounds good," which is notable because I was using the hand-mike that came with the rig.

Overall, it is the quality and action of the FT-990's controls that impressed me the most.

Receive Performance

My antenna system is designed to instantly switch from one rig to another, and can be set to parallel rigs on the same feedline. This provides a means to compare performance. During the review process, I operated only in SSB, FM, AM, and CW modes, even though the FT-990 is built with internal interfaces for digital modes (RTTY, packet, AMTOR). I was very pleased with the general receiving capabilities of the FT-990 and I feel it will meet most needs. I still think that the FT-1000 has what I feel to be the ultimate receiver, but it is, after all, more expensive than the FT-990.

The rig I tested had the 2 kHz SSB and 250 Hz filters installed. I found that for signal separation, using these optional filters gave a distinct edge. Overall, the receiver is very tight and does not appear to suffer overloading problems caused by nearby strong signals.

Features and Comments

The Digital SCF filtering is super! I cannot say enough good about this feature. I used it often and was very pleased with its power and ease of operation. The filter consists of two controls that limit the audio bandwidth of the received signal. One cuts out the highs and the other the lows. Both are infinitely selectable and have very steep skirts. This filter is a real plus that isn't even found on the FT-1000.

The SHIFT (IF passband) control is great to use, smoother and broader (easier to tune) than most other rigs. Although the NOTCH FILTER works like it should, I've found that there are some tremendous automatic notch filters in the add-on market. It'd sure be great to see this kind of noth filter available in commercial rigs.

The RF FSP speech processor is unique in that it has a provision for shifting your transmit frequency. It is most effective during pile-ups. The slightly higher-sounding audio really cuts through. Just don't use it on 75 and 40 for local work. You won't be liked very much. This feature can be cloned by operating split, using two VFOs, or by using RIT. But, I doubt if you would consistently be as good sounding or as effective as the FT-990.

If you have never used a rig with an automatic antenna tuner, treat yourself to it sometime. I used multiband wire and vertical antennas for most of my HF work and found the 990's automatic tuner to be perfect for fast QSY. It tuned everything I normally use, with no problems. It did balk at working with my linear amplifier, so in those situations I turned the tuner off.

There is a nice feel to the tuning knob and all the controls are of excellent quality both visually and functionally.

The front feet on the rig are far nicer than the typical wire bails found on most rigs. They drop out of the case bottom, are round, and large in diameter. They are also non-slip!

For the CW operator, a built-in iambic memory keyer with dot/dash memory and selectable weight is standard. The keyer can even be set to simulate a bug. The BFO frequency is adjustable, and a SPOT button allows for precise tuning. A 500 Hz CW filter is standard with 250 Hz optional.

Each of the 90 memories stores frequency, mode, bandwidth, and clarifier (RIT) settings. They are scannable, perhaps nice for keeping track of activity on favorite nets or for FM.

The DVS-2 digital voice recorder (optional device) is basically a solid-state tape recorder.

It is convenient for calling CQ and, with the four short message sections, can be set up to XMIT most of a contest contact. Recording off-the-air is a good feature for repeating missed calls and contact numbers. In addition, as many hams really do wonder what they sound like on the air, particularly when making mike and/or audio changes to their stations, being able to play back on the air is a great feature.

Yaesu does not recommend long transmissions at full power on the FT-990 when operating digital modes. They suggest operating at half power.

The Manual

The manual for the FT-990 includes an excellent tutorial to get you going and does a good job of explaining the function of each control. It is a must-read booklet, as it contains instructions for customizing the transceiver for your own operation (power-up selections). I found the manual lacked some specifications (no stated dynamic range).

Customizing the FT-990

You can customize some of the operations of the FT-990 to suit your particular desires by instructing the rig how to come on when powered up (turned on).

Power-up selection choices are made by holding specified keys/buttons while switching the FT-990 from "off" to "on," and by using DIP switches. Once selected, these choices will be included every time the rig is turned on (until you change them). Some power-up selections are: method of frequency display (offsets for different modes), beeper on/off and pitch, 10 Hz readout, CW pitch, and sidetone volume. This capability makes it easy to turn the 990 into *your* radio.

Recommendations

At a suggested list price of $2,399 you will be getting a high-grade transceiver loaded with bells and whistles, internal power supply, automatic antenna tuner, and digital SCF audio filtering. The rig is also ready for any current digital mode.

Putting these prices into perspective, the FT-990 isn't such a case of sticker shock after all. All you need for general operation is a single all-band antenna such as a G5RV or Windom, a feedline, and a place to plug in the FT-990.

Would I recommend the FT-990? Yes, it offers the features most hams are looking for. Its controls are smooth and very effective, particularly the digital SCF audio filter and shift tuning. And, let's face it, the rig does look pretty darn good!

Some Features of the FT-990

Keypad direct frequency entry
Passband shift
90 memories
Automatic antenna tuner
Dual digital SCF (switched capacitance filter) audio filter
Noise blanker
RF FSP (frequency-shifted speech processor)
All-mode squelch
Notch filter (manual)
Iambic memory keyer
Selectable BFO offset
Spotting button
Key jacks on front and rear panels
Dedicated interfaces for RTTY, AMTOR, and packet
Internal switching AC power supply
DVS-2 digital voice recorder (optional)
10 meter FM operation

SPECIFICATIONS (as taken from the FT-990 Operating Manual)

General
RCVR Coverage: 100 kHz–30 MHz
XMIT coverage

160	1.8– 2.0 MHz
80	3.5– 4.0 MHz
40	7.0– 7.5 MHz
30	10.0–10.5 MHz
20	14.0–14.5 MHz
17	18.0–18.5 MHz
15	21.0–21.5 MHz
12	24.5–25.0 MHz
10	28.0–29.7 MHz

Frequency Stability
<10ppm (−10 to +50 degrees C)
<0.5 ppm (w/TCXO-2 option)

Audio output impedance: 4–8 Ω

The QUAG-V

A high performance and wide bandwidth antenna for VHF and UHF.

by Leonard Shick WB3AYW

A broadband antenna is a must for 440-450 MHz. The main problem of most antennas (as well as the matching system) for this band is the ability to achieve a low VSWR over a wide bandwidth while maintaining a high gain. This limits most antennas to a bandwidth of 1 or 2 MHz. By using quagi dimensions for directors and all spacings, the bandwidth of the driven element can be widened to 10 MHz by changing the driven element and the reflector to the double quad design, then bending them at a 90 degree angle. When this is done, all three radiating elements on the driven element reinforce each other at the first director for added gain on both receive and transmit.

In an antenna system with two quad loops driven at the center, there is an impedance of approximately 75 ohms. When used in an array, this can drop to around 50 ohms, which can be driven with 50 ohm coax directly without any matching device. This helps with the simplicity of the easy-to-build broadband design.

Construction Details

The antenna is made from #10 AWG house wiring because of its stiffness and low cost. The boom is made from wood (1" x 2" pine for 70cm and 1" x 3" for 2m). DO NOT USE METAL, as it will interfere with the element length and radiation pattern.

Using a #39 bit, drill all the holes in the boom, except the one for the driven element, which does not get drilled completely through. The undrilled part of the boom between the two holes keeps the two wires from

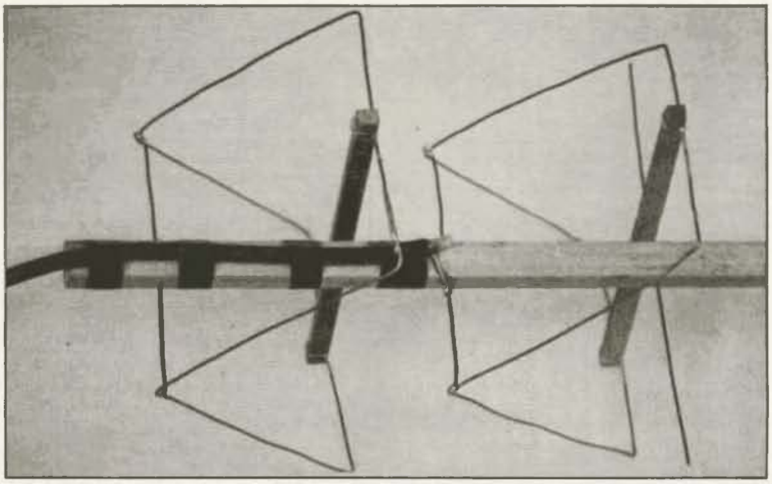

Photo A. Close-up view of the driven element, reflector and feedline attachment point.

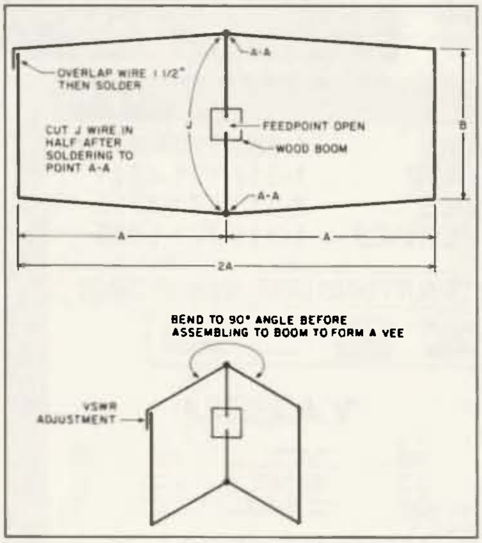

Figure 1. The driven element.

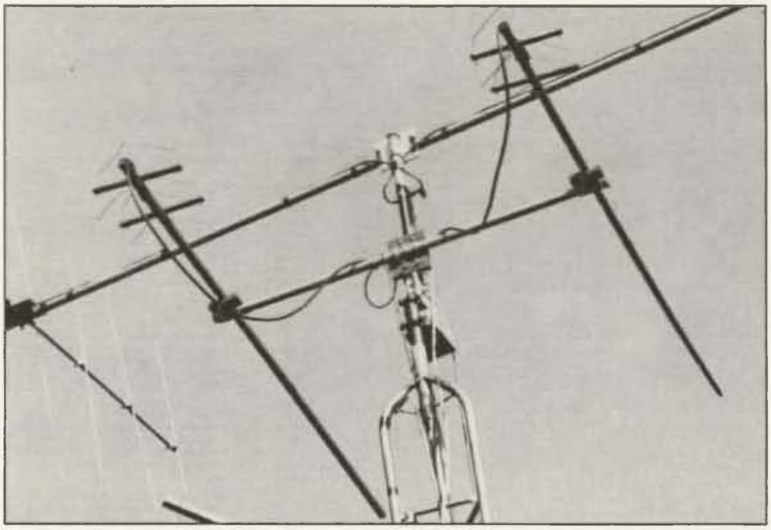

Photo B. Two Quag-Vs can be stacked for additional gain. If you mount the Quag-Vs for horizontal polarization in the configuration shown, you must use a wooden or fiberglass cross support.

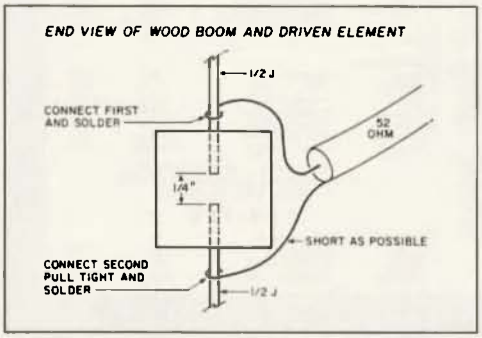

Figure 2. Feedline connection to the driven element.

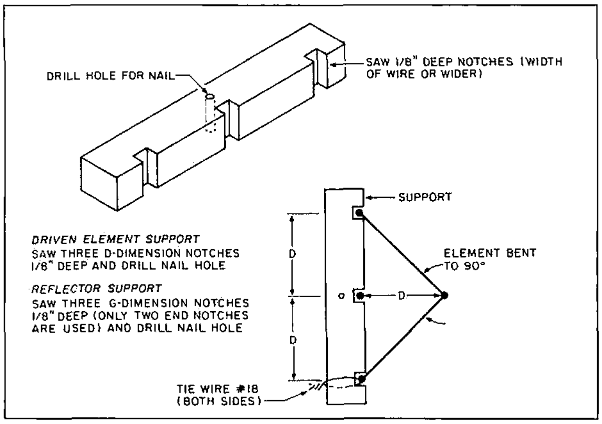

Figure 3. Top view of the driven element and reflector support. The elements are held in place by short loops of #18 wire as shown. The "D" dimensions are used for the driven element and the "G" dimensions are for the reflector assembly (see Table 2).

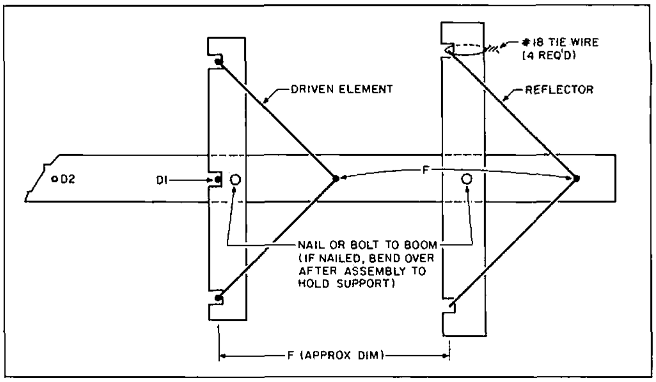

Figure 5. Top view of the driven element and the cross support assembled and attached to the boom.

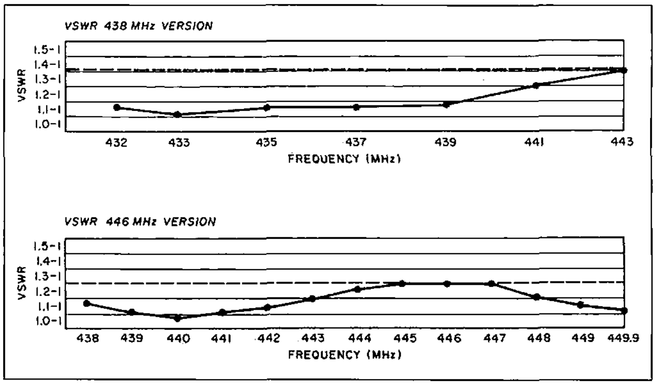

Figure 7. VSWR plots for the 438 MHz and 446 MHz versions.

touching at the feedpoint, and is also the driven element center support (see Figures 1 and 2).

The directors must be cut for the higher portion of the band to be used, so as not to act as reflectors at the highest frequency used. When making the directors, cut carefully, file both ends flat, and then deburr to get the correct length. (A burr on one end of an element can change the length by one MHz or more.)

When mounting the directors, wrap some #18 bare wire around the directors on both sides of the boom, then solder so that the elements will not slide down through the boom.

If the antenna is to be stacked side by side for vertical radiation, the mast can be metal as it will not affect the pattern. For horizontal operation, the mast and supporting structure should be nonmetallic if they are in the field of the radiation pattern.

The support for the front of the driven element and reflector is made of wood, approximately 1/4" x 1" x 12" long. The center of the two wood cross supports is held in place by a nail approximately 2" long, bent over to hold the support from moving. Three notches position the elements in place and two #18 tie wires hold and support the elements to the supports. This ensures that all three vertical elements are the same distance from the first director.

The coax should go from the driven element back through the reflector, then be looped back to the supporting structure. The mast should be of a non-conducting material: wood, fiberglass, etc. A metal mast will change the gain and pattern of the system.

Tuning

When the antenna is complete, adjust the

VSWR by unsoldering the side of the driven element where it is soldered together, then slide it to increase or decrease the length. When you have completed the antenna, and before installation, coat the wood with a latex-base finish to protect it from the weather.

This antenna is similar to the parabeam ("J" beam), but uses the quagi spacings and is bent so that the first director is in line with the outside of the driven element.

At the 1991 W3MIE Field Day, site tests were conducted on the 440–450 QUAG-V, and it showed a much-improved gain and bandwidth over a quagi of the same size. ■

Computerized Tuning for Ramsey Receiver Kits

It doesn't have to be expensive.

by Mike Gray N8KDD

Computer controlled tuning is generally considered the domain of only very expensive receivers. It doesn't have to be that way. This project will show you how to convert an inexpensive receiver kit from a manually tuned radio to a scanning receiver with 10 memory locations.

Receiver kits from Ramsey Electronics are tuned using a varactor diode. A bias voltage is applied to the diode, changing circuit capacitance as a function of the bias voltage. The capacitance is not linear with respect to the voltage, so a little slug tweaking is required to optimize the resolution for the band segment you are interested in. The tuning potentiometers provided with the kits are of high quality, but because they are linear the tuning resolution is reduced at low voltage. In other words, you can't expect as much selectivity when the bias voltage is low. This is not really a problem, and it isn't evident until you find that you have been turning the knob a little too fast and missing some active frequencies. A large diameter tuning knob will make an improvement.

These receivers are an excellent buy, and they perform very well. You can do a lot of experimentation with them without fear of creating a smoldering pile on the bench.

Using these receivers is a lot more fun when a computer does the work. Because computers are digital and the radio kits are analog, a digital-to-analog interface is required. The computer and interface do the same job as the tuning potentiometer, and allow automated control and scanning, too. Computerized tuning allows you to return to a particular frequency easily and accurately. Although absolute frequency cannot be determined without a frequency counter, a very close approximation can be made just by listening for scheduled nets. When you have a couple of absolute frequencies assigned to channels, you can use them as landmarks for unknown frequencies. A frequency counter is not necessary. Ramsey Electronics includes tuning suggestions in the kit documentation.

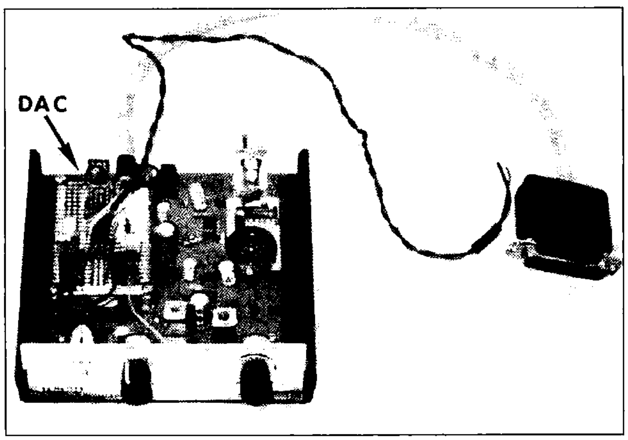

Photo A. Modified receiver (prototype).

Digital-to-Analog Converter (DAC)

The DAC reads 8 bits of data from the computer, then converts them to counts which represent some fraction of the reference voltage applied to the DAC. Two hundred fifty-five counts is equal to 5 volts. An LM10CN op amp is used to buffer the output from the DAC and double the DAC output voltage.

Some of the features of the DAC chip have been disabled because they are not required for this simple project. Only 10 wires connect the DAC assembly to the computer. Eight lines are for data, one is for DAC control, and one is ground reference.

The DAC and receiver together draw less than 25 mA, and both must be powered from a clean 12–13 volt source. The receiver isn't very particular about the supply voltage, but the DAC chip is. It must be powered by a supply which is at least 7 volts higher than its reference. You will have to remove the 9 volt battery holder from the receiver anyway, to make room for the DAC assembly.

Receiver Modification

This really couldn't be easier. Simply remove the tuning potentiometer and run a wire from the DAC assembly output to the center solder pad on the receiver board. Then run another wire from the grounded solder pad to ground on the DAC assembly. The figure shows an HR-4 40 meter receiver. UHF/VHF kits will be similar.

Connect a clean 12 volt (nominal) power supply or battery in place of the 9 volt battery on the receiver board. Make sure the polarity is right. I can't tell you what will happen if it's wrong, but it can't be anything good.

Power for the DAC is taken from the center terminal of the power switch on the receiver kit. Just connect a wire from the top side of the switch to the DAC. That way, the front panel switch controls both boards.

These receivers are very sensitive. You must use a coaxial feedline, and locate the antenna at least 12 feet away from the computer, otherwise you may be listening to computer generated noise. The amplitude of the noise depends upon the receiver frequency, and the clock rate of your computer. A 7 MHz computer will wreak havoc with a 40 meter receiver if the antenna is too close.

I had added an amplifier and a Radio Shack piezo-electric audio transducer to my receiver during the course of a previous experiment. The assembly is located near the antenna connector. It's a big improvement over an earphone, and it sounds pretty good, too.

DAC Construction

The entire assembly could be built on a Radio Shack plated PC board. Photo A shows a switch in my prototype which is not required in the final version. The switch allows the gain of the op amp to be fixed or variable.

We need adjustable gain, so the switch is not included in the schematic.

To attach the DAC board to the receiver board, screw a threaded spacer to each corner of the DAC board. Then apply a little epoxy to the bottom of each spacer and set the assembly on the receiver board.

You can use ribbon or bundled cable to connect the DAC to the 25-in. connector. A complete printer cable can be bought for about $8 from computer discount houses. Buying a printer cable might be cheaper than buying the connector and wire separately. Just cut the printer connector off, and using an ohmmeter, find the wires for pins 1-9 and 25.

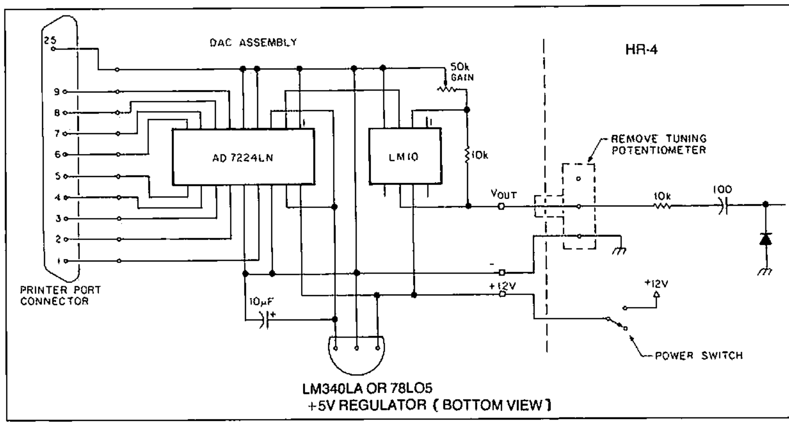

Figure 1. Schematic of the computer interface.

Software

The computer controls the WR line of the DAC chip, and supplies the 8-bit data word, which the chip converts to a voltage. The program must toggle the WR line, and send 8 bits of data to the DAC. The DAC chip will latch the output voltage at the most recent level, until instructed to change it or power is lost.

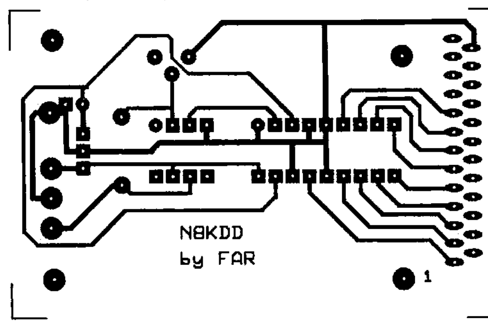

Figure 2. PC board.

The program listing in the sidebar is the minimum required to produce an output voltage from the DAC. The listing prompts you to enter the desired output value in counts.

After you finish assembly of the digital-to-analog converter, run the program and enter 255 counts. Turn the potentiometer until the voltage at pin 6 of the LM10 is 10 volts.

The address of the printer port of most computers is 888. If the circuit does not respond, change address 888 to 956, and change address 890 to 958.

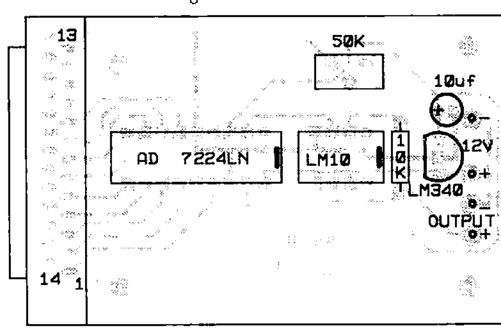

Figure 3. Parts layout.

Find an active frequency by entering a value from zero to 255 when the program prompts you for it. Each time you find activity, write down the D/A counts so that you can return to that frequency just by entering the number. The program kernel shown in the sidebar is intended for experimentation. In order to realize the advantages of computer tuning, a more sophisticated program is in order.

My program is much too long to list completely here. You can write your own program or download mine from the *73* BBS at (603) 525-4438. The name of the program is DAC-TUNE.ZIP, and it will run on PC compatibles with CGA graphics. I can also supply the program on a diskette for $6.

The DAC-TUNE program can scan the entire band (global search), or station presets. When you hit any key, the program stops scanning and executes the command associated with that key. Manual tuning is accomplished with the left and right arrow keys. When you find an active frequency, you can assign it to a channel. You can return to any channel simply by entering the channel number. Station presets, frequencies, and screen colors are saved in a file called SETUP when you terminate the program. These are recalled automatically the next time you start the program. The program operation is self-explanatory.

The DAC chip is relatively new and can be purchased only in lots of 10 or more from the distributor. I can offer kits which include a printed circuit board, DAC-TUNE software, and components. I have not included a printer cable, because cables are often available cheap or free locally. A kit costs $30, which includes shipping and tax. If you just want the 7224 DAC, it's available for $10. The blank PC board is available for $6.

The receiver kits are available from *Ramsey Electronics, Inc., 793 Canning Parkway, Victor NY 14564.*

ICOM IC-2SRA 2 Meter HT and Scanner

A full-feature 2 meter handheld with a separate wideband receiver.

ICOM America, Inc.
2380-116th Ave. N.E.
Bellevue WA 98004
Telephone: (206) 454-8155; FAX: (206) 454-1509
Price Class: $600

ICOM's new IC-2SRA should really get the attention of the avid ham and dedicated scanner enthusiast. Not only is it a 2 meter hand-held,it also has a built-in wideband scanner receiver.

Two Antennas???

The IC-2SRA looks exactly like the popular ICOM dual-band 2 meter/440 MHz IC-W2A. The buttons, oval magnified LCD screen, and top knob placement are identical. Even the little red power-on button is the same as the ICOM IC-W2A.

But there IS one thing that immediately sets the two units apart when you put them side by side —the IC-2SRA boasts two antennas coming out of the top. That's right, folks—antennas in stereo.

On the first look, you might think someone is teasing you by sticking an antenna speaker/microphone jack on the top of the unit. In fact, when you take a close look at the top of the 2 meter scanner, you'll see that the two jacks are absolutely identical—the left jack for the speaker/mike, and the right jack for the supplied wideband rubber ducky. No BNC jack—no TNC jack—simply an earphone-type jack that the wideband scanning antenna plugs into. It seems to make a good connection, but nonetheless, an earphone jack for an antenna connection?

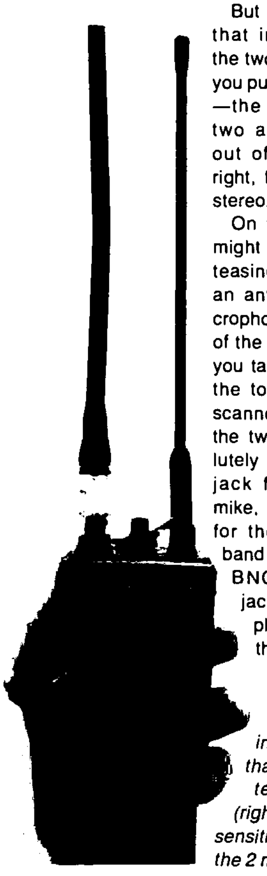

Photo B. Antennas in stereo! We found that the wideband antenna for scanning (right) was not quite as sensitive on 2 meters as the 2 meter ducky (left).

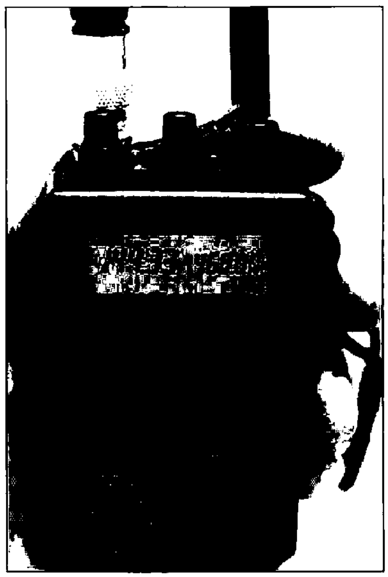

Photo A. The IC-2SRA, showing the 2 meter readout (left) and the scanner frequency readout (right).

The 2 meter side of the ICOM IC-2SRA hand-held transceiver/scanner seems identical to the IC-W2A receiver. The 2 meter receiver tunes from 136.000 MHz to 174.000 MHz, and transmits from 140.000 MHz to 149.995 MHz. We measured in-band receive sensitivity at 0.095 μV for 12 dB SINAD, and 30 kHz selectivity at −60 dB. The 2 meter receiver gave us the good performance we have always found with ICOM hand-held transceivers, in both single-band and dual-band models.

We tested the 2 meter receiver on an outside antenna. There were absolutely no surprises when it came to good rejection to out-of-band paging transmitters, local weather stations, and numerous other high-band signals blanketing my local QTH. On the same outside antenna, some other brand HTs have not fared as well—but, as usual, the 2 meter receiver was nice and tight in a heavy RF area.

The 2 meter transmitter pops on at 140.000 MHz and cycles off at 149.995 MHz. This is good news for those of you in the United States Coast Guard Auxiliary, Civil Air Patrol, or MARS. As soon as you unpack the unit you are on the air on those government frequencies, if you've got the proper license.

Push-Button Programming

Four levels of power output are available from the push buttons. (Table 1 shows what we measured.) When you first set up the programming of your handheld, you may dial in exactly how low you want your low-power output to be. I chose the lowest setting—Low 1—because this only draws 478 mA on my high-power battery pack, as opposed to a whopping 1.34 amps on high power.

The 2 meter side of this transceiver/scanner features all the functions and sub-functions found with a sophisticated handheld. It will take you some time to learn all of the programming steps to

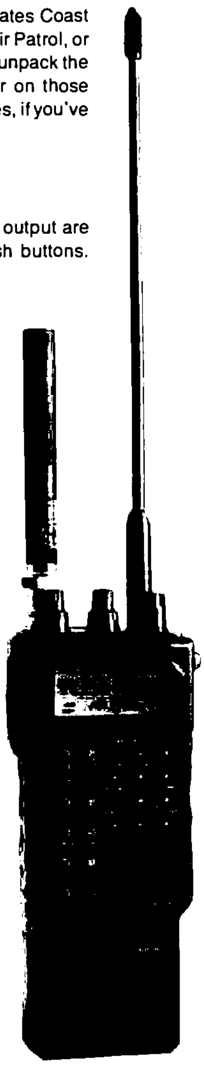

Photo C. The 440 MHz version of the transceiver/scanner. Remember, it is ***NOT*** *a dual-band, only dual-receive.*

Power Selection	12.5 Volts	7.2 Volt Battery
High	5.1 watts	1.6 watts
Low 3	3.2 watts	1.5 watts
Low 2	1.3 watts	1.5 watts
Low 1	0.4 watts	0.4 watts

Table 1. Available power output from push-button selections.

Receive limits: 25.000 MHz through 950.000 MHz
No locked-out band segments; few birdies
Modes: AM, FM, wideband FM
Average NBFM sensitivity throughout band: 0.32 µV for 12dB SINAD
Receiver type: Triple-conversion superhet
Tuning steps: 5, 10, 12.5, 15, 20, 25, 30, 50, 100 kHz (VHF band);
10, 12.5, 20, 25, 30, 50, 100 kHz (UHF and 800 MHz–950 MHz)

Table 2. Scanner/receiver features.

set in your favorite repeater and simplex frequencies in the 30 memory channels, plus the single call channel and two-frequency band edge channels.

Of course, what's a 2 meter transceiver without a clock? That same clock that can turn your unit on can also shut it off. In fact, the clock button is right next to the "enter" button, so you might be seeing the clock come up a lot more often than you want to until you get more precise at poking away at the closely-spaced rubber keypads.

Built-in Scanner

Early press releases indicate that this single-band 2 meter or 440 handheld contains a built-in "wideband receiver." What they are saying is that the single-band 2 meter or the single-band 440 handheld has a built-in, wideband, multimode, 60-memory-channel scanner. (Table 2 lists what we found in the separate built-in scanner/receiver.)

The wideband scanner/receiver is not part part of the main transceiver receiver section. Rather, it's absolutely separate, with its own right-hand LCD readout, antenna port, volume and squelch knob

CH	VIDEO	AUDIO
2	55.25	59.75

13	211.25	215.75

Table 3. TV channels 2–13 audio frequency assignments tuned "WFM" mode on the ICOM IC-2SRA scanner.

squelch knob, and automatic turn-off when you are actually transmitting on the 2 meter band.

This prevents feedback, desense, and potential damage if you're receiving on the same frequency as your transceiver is transmitting. We made that test, and as soon as we hit the PTT the receiver simply blanked out.

And speaking of blanking out—when you begin to program the wideband receiver, as soon as you hit the enter button, the screen goes blank. Do not worry! Start punching in numbers, and the screen jumps to life. This is different from what occurs on the 2 meter side of the radio. On 2 meters there are always a couple of leading numbers to let you know where you are, but on the receive-only side of this transceiver the screen blanks out to allow you to punch in anything from 25 to 950 MHz.

Use the AM mode for tuning in the aeronautical band, the 27 MHz band, or some aeronautical military frequencies in the 200–300 MHz band.

Use the FM mode to listen to regular two-way radio communications. For listening to some pop music on the FM music band, use the WFM (wideband FM) mode. It's easy to select the mode—simply press a single mode key. Be sure to add a leading zero to any direct-dial frequency below 100 MHz. If you don't, you won't hear your popular FM music station at 88.5, because your radio is at 885 MHz!

In the wideband FM mode, you can easily tune into all television audio channels. It comes out crystal clear (except for a birdie on 71.75 MHz, TV audio channel 4, which ICOM indicates they will try and cure), and has a lot more fidelity than trying to tune into a ball game on an old-fashioned AM portable radio. Spend a few minutes, and store your local TV audio channels in the memory for quick retrieval. You can always search out the audio by setting the squelch, and then electronically scanning up. Of course, you can do this at the same time as you are working on the 2 meter side of your transceiver. (See Table 3.)

Unfortunately, the receiver does not go all the way down to shortwave or AM broadcast band frequencies. The lowest you can tune is 25 MHz, and with that little tiny, skinny, rubber duck antenna, any signal below 40 MHz better be real strong.

There will be some ICOM products coming down the line, specifically for tuning in the shortwave bands, but this one won't go below 25 MHz.

To increase your scanner reception, solder up a miniature plug with micro-sized coaxial cable or a good shielded short piece of audio cable. Terminate that to a BNC jack, and this would allow you to plug into a regular outside antenna for improved reception. But a word of caution: The scanner antenna jack is little more than an audio plug receptacle, so don't even consider running a regular piece of RG58AU to it. It could cause the jack to fail.

Another word of caution: The engineers at ICOM recommended at least five feet separation between any external antenna hooked into the antenna jack from a regular transmitting VHF or UHF antenna. I tried this set-up, and didn't blow the receiver—but be careful. With any scanner on an outside antenna, permanent front-end damage might occur if your scanner antenna gets right next to a high-power transmitting antenna.

As for selectivity and intermod rejection, the triple conversion receiver did a good job of canceling out the stuff not on frequency.

I would have preferred a BNC or TNC type connector for the scanner antenna, and it would also have been nice to give you a little bit more "finger room" between the second antenna and the main tuning knob. Also, don't be surprised that the plug-in charger that comes with this unit features yet another design not found on those octopus charging plugs with multiple adapters. But good news—if you already own some ICOM products, the battery packs may be interchangeable, and this includes the drop-in charger, too.

If you are into both 2 meter and 440 MHz (separate units), and also want a built-in scanner, do consider this new offering from ICOM. The scanner capabilities were just as good as with a regular-sized pocket scanner, and the audio a whole lot better from the ICOM communications-style speaker. Best of all, it's one radio with both a built-in ham band and a scanner. 73

Not Just Another Island

Weekend DXpedition activates the Walrus Islands.

by Bob King NL7KH

The Walrus Islands are a group of five small islands in the Bering Sea, tucked in along the southwestern shoreline of mainland Alaska. These islands are uninhabited for most of the year, but in the summer their population swells with hundreds of thousands of seabirds—puffins, kittiwakes, auklets and murres.

Thousands of walrus also make the islands their summer home. Male walrus only, though. While the females take care of their young farther north, the men haul out on Round Island, feasting on clams and tanning their bodies on the gravel beaches. It's the ideal bachelor pad, if you happen to be a one-ton pinniped!

Human visitors are rare. Adventuresome wildlife enthusiasts who can afford the trip will venture to the islands to view the walrus and the spectacle of thousands of cliff-dwelling birds. Commercial fishermen are also familiar with the nearby waters, where they cast their nets for herring, salmon, halibut and sole. But before this June, the Walrus Islands have been unknown to the ranks of amateur radio.

Photo A. The KL7N camp on remote Crooked Island, in the Walrus Island chain.

An Island "Vacation"?

"Back in 1988, Chod Harris VP2ML wrote a column for *73* (see DX, July 1988, p. 87) about a group called Islands on the Air," said Scott Diseth KL7N. "In it he explained what IOTA was all about and what islands qualified for the program. He mentioned that Alaska has 24 potential credits, 14 of which have been on the air. Anyone for a DXpedition to Walrus Island this summer?" he asked, kind of tongue-in-cheek.

IOTA members, or "island chasers," as they're known, collect contacts from as many islands or island groups around the world as possible. Many islands, like Hawaii, New Zealand and the Bahamas, are relatively easy catches, but the prospect of a new group like the Walrus Islands was tempting. *[Ed. Note: The IOTA group meets on 14.260 MHz at 1300 UTC Saturdays, 21.260 MHz at 1400 UTC Sundays and on 28.460 MHz just about anytime. Also a list of potential island credits "The IOTA Directory," is available to U.S. residents for $4 ppd. from* The DX Bulletin, *Box 50, Fulton CA 95439.]* Scott, a resident of Dillingham, Alaska, just 60 miles from the island group, decided it was time to take up the challenge. "None of us are IOTA members, but it seemed obvious to me that the Walrus Islands were a rare one, something that people wanted, and it was right in our back yard," he said. "It was kind of a lark, but we were the only ones qualified to activate the islands." Joining KL7N in the expedition were Les Robinson KL7KN, Mike Megli AL7KA and Bob King NL7KH, all residents of Dillingham.

Getting There

Even though the islands are not far away, getting to them was an expedition in itself. Round Island, home to most of the walrus, is a state game sanctuary and access is restricted, so the expedition chose Crooked Island, the second largest island in the chain.

Crooked Island, however, is accessible only by boat or floatplane. Fortunately, the owner of Yute Air Alaska, a Dillingham-based air taxi,

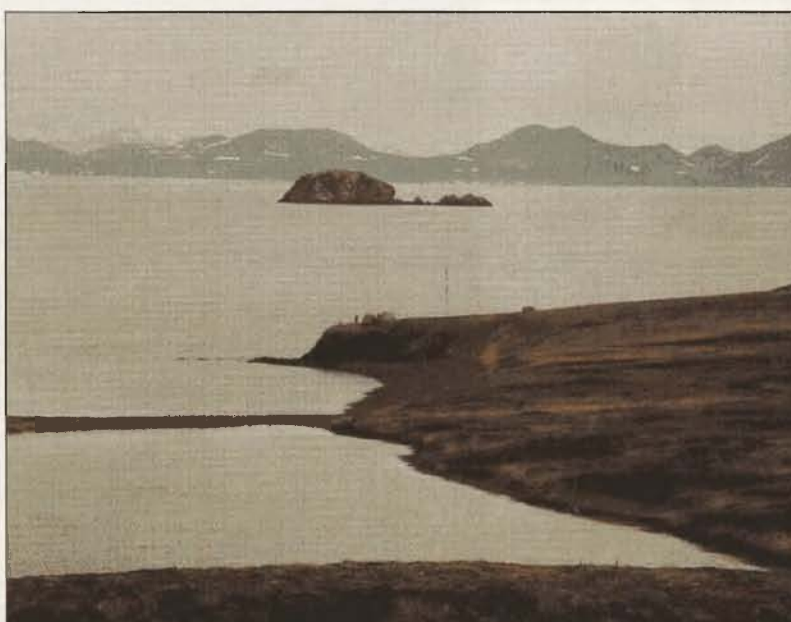

Photo B. The KL7N site and antenna farm on Crooked Island.

is an active ham himself. Will Johnson WA0LKT and one of his pilots, Steve Huddleston KB5GAH, volunteered to help with the transportation. To expedite matters, Steve ferried planeloads of equipment to a beach halfway to the islands, and from there it was transferred to Will and his Cessna 206 on amphibious floats.

It took three trips on each leg. Some of the larger equipment, including a 35-foot crank-up tower and the disassembled antennas, had to be strapped to the plane's floats.

Scott rode over on the first flight to select the site and set up camp. "On the first flight, we took the antennas, the tower, and enough gear for me to survive in case nobody else made it," he said. "You never know what's going to happen."

Fortunately, the weather cooperated with the DXpedition. The skies were sunny and the winds were calm as Will shuttled back and forth with equipment and Scott began to set up the tents and a small farm of antennas.

The radio tent held a Kenwood TS-440 and a Heath SB-200 amplifier. Since the linear drew almost all the current of the generator, the transceiver was run off batteries which were recharged at night. The signal was fed into a Hy-Gain TH-3-JR yagi atop a Tri-Ex 35-foot crank-up tower. A home-brew phased vertical was used as a backup. Having a backup became important as soon as Murphy made his first appearance on the island: Inevitably, the one box that got left back in the hangar 60 miles away contained all the group's tools.

"Yeah, things went pretty smooth, except for forgetting our tools and extension cords," Scott later joked. "But, using some ingenuity, we rigged up a phased vertical system with Mike's leatherman tool and Les's Swiss Army knife. That wasn't enough to put the yagi together, but it worked for the vertical. So score another one for the Swiss Army knife!"

Photo C. Members of the Walrus Island group (l. to r.): Scott Diseth KL7N, Les Robinson KL7KN, Bob King NL7KH and Mike Megli AL7KA.

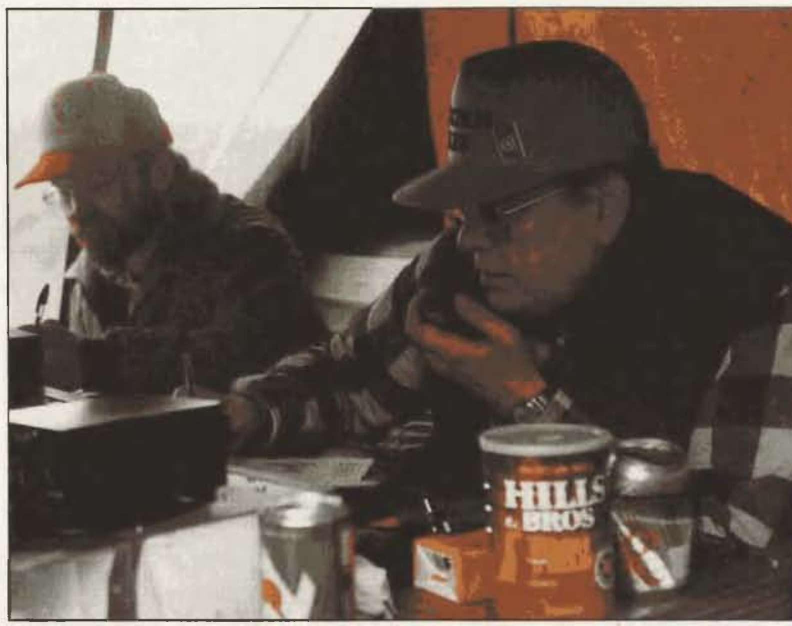

Photo D. Scott KL7N logs contacts while Les KL7KN works the pile-ups.

On the Air

We were still struggling to assemble the antenna, and running out of options on our Swiss Army knife to do it with, when somebody asked, "What time is it?"

The sun was still high in the Alaskan evening sky, but it was already ten minutes past nine. Ten minutes late for our first sked.

Hurriedly, we hooked the rig up to the half-erected vertical just to see if anybody was waiting. Scott whirled the dial on his TS-440 to 14.260 and, sure enough, there was already a pile-up trying to contact KL7N, portable Walrus Island.

With the phased vertical directed north and the rig running barefoot due to the lack of extension cords, KL7N activated the Walrus Island group, designated by IOTA as NA-121, at 0528Z on June 2, 1990.

The first contact came off the side of the antenna, from "Doc" Khalsa KD7SO, in Eugene, Oregon. Doc is IOTA's point man on the West Coast and had helped Scott arrange publicity about the expedition. He had been among those calling for KL7N. In fact, when the group missed its 9 p.m. sked, he had begun to get worried.

"When we were late, Doc called my wife Vickie to find out what had happened to us," Scott recalled. "He was on the phone at 0515 and Vickie assured him that we were out there."

After logging his first 59 report, Scott worked a few more stateside contacts and, as luck would have it, Will's Cessna unexpectedly buzzed the camp to announce the belated arrival of the toolbox. The plane gingerly taxied up to the rocky shoreline. The yagi was quickly assembled and NA-121 was in business.

Over the next day and a half, KL7N logged 464 contacts in 42 countries and most of the United States. Most of the calls came on the IOTA frequency of 14.260, but a few contacts were also made on the 15 and 40 meter bands.

Europeans are the most eager island chasers by far. Contacts were quickly made in England, France, Germany and Italy, throughout Scandinavia, and in Spain and Portugal. Signals flowed freely over the now-crumbled Iron Curtain from East Germany, Poland and Czechoslovakia. Latvian and Estonian hams lined up with Russians to swap reports with KL7N, but it was a most orderly pile-up.

Johnnie Varetto I1HYW provided net control on the continent and ran a tight show, which was appreciated back on the island. "It was kind of a free-for-all with the Americans," Scott said. "It seems like IOTA is a

lot more popular with the Europeans. They're a lot more organized."

While members of the KL7N group took turns making contacts, others hiked around the island, beachcombed, and even tasted herring roe on kelp—a Japanese delicacy which is collected by commercial fishermen on nearby beaches. On Saturday, Will shuttled some of the expedition's families over for a visit. Scott's son Alex celebrated his sixth birthday playing along the shoreline of Crooked Island while his father worked DX, including a call from his father-in-law, Walt Wilson K8AEM, in Marshall, Michigan.

"We cleared the frequency for that," said Scott. "That was the biggest thing that ever happened to Walt."

Actually, Walt has been an invaluable friend of amateur radio in Dillingham. Over the years he has helped get gear for just about every ham in the isolated fishing community. Having a stateside connection is a necessity for hams in remote places like Dillingham, where the nearest Radio Shack is 350 miles away.

Walt also kept tabs on the expedition throughout the weekend. Since almost all the hams in Dillingham were on the island, Scott's wife Vickie had to call her father in Michigan to make sure the group had arrived safely. Mike was able to finally reach home through the Dillingham repeater, but it took an evening climb up a thousand-foot peak, and a ⅝-wave whip on his handie-talkie, to raise the carrier.

Next Time...

Back home now, Scott has been busy verifying the QSL cards he has received not only from hams but from the many SWLers who monitored the expedition.

Despite the complicated logistics and occasional mis-cues, Scott credited the relative ease of the undertaking to past Field Day work. "Without the Field Day experience, we wouldn't have been able to put it together," he said.

"But, I think everybody is Field Day'ed out. I doubt if the Dillingham Club will be on the air this year. Even a weekend DXpedition is kind of a Field Day to the extreme."

But would he reactivate the island again? "Yeah, I think I would in a couple of years," said Scott. "I don't think we worked everybody. There are 2,000 members of IOTA, so it sounds like we only worked a quarter of them. There must be others out there that still need Walrus Island.

And I won't forget my tools," Scott added with a laugh. "Actually, I would have spread my tools out. I wouldn't have had them all in one box."

Scott also said that next time he would try to give IOTA members more advance notice. The KL7N group went out with just two weeks notice. But longer lead time is not always possible in the Bering Sea.

"The problem with those islands is the weather. You can't stick your necks out two months in advance and say you're going to go, because you can't even be sure you're going to make it. 73

HAM HELP

Your Bulletin Board

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full (8½" x 11") sheet of paper. You may also upload a listing as E-mail to Sysop to the 73 BBS/73 MAG Message Area #1. (2400 baud, 8 data bits, no parity, 1 stop bit. (603) 525-4438). Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters 1 or i, or even the number 7. Specifically mention that your message is for the Ham Help Column. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

Wanted: A copy of the manual for Dentron 160-10L with 8lla tube, or info on converting 160-10L/572B to 811A. I will pay copy cost and shipping. Ship to *NP4XB/4* or call *(407) 273-3335* from 9 to 5 EST.

I have a Side Band Engineers (SBE)-33. I would like a copy of the schematic and the operating manual. I will be happy to pay postage and copying costs. Thank you. *Joel Kaplan WA7ERH, 1425 E. Ocotillo Rd. #2, Phoenix AZ 85016. (602) 277-2832.*

Wanted by handi-ham: Older HF SSB rig or 2 meter FM equipment dead or alive, inexpensive to repair. Please write to *N3IMJ, 257 Sebring Ave., Pittsburgh PA 15216.*

Wanted: Operating manuals and schematics for Hallicrafter SX-42 (Skyrider Panoramic) 6-band general coverage receiver and Johnson Viking Messenger I (5 channel "white face") 11-meter transceiver. Originals or copies are fine. I will gladly pay duplicating costs and postage. *Kelly Andrews, 8608 Timberwind Dr., Raleigh NC 27615. Day phone (919) 870-0315; evening phone (919) 870-6923.*

Needed: Service and/or operating manual for Hallicrafter's SX-99. I will pay for original or copy. *Luther Hollums N4KTC, 15103 Mahogany Dr., Boynton Beach FL 33436.*

H-T POWER FOR LIFE!

The Quantum Ham Battery™ may be the last rechargeable battery you'll purchase. Its 12 volt 2.1 **amp hour** capacity packs up to six times the power of H-T nicad packs.

A simple coiled cord connects Quantum's power to your H-T. If you buy another H-T just get another cord — without the additional cost of new batteries and chargers. The Ham Battery will power all sorts of 12 volt gear — past, present and future.

You'll always know how much power remains. The battery's status is continuously monitored by a unique L.E.D. display. Its sealed lead cells maintain charge for months and recharge reliably to 100% capacity without the "memory" effect of nicads.

You'll have the power you need when you need it—for emergencies, events, field day, camping, boating, camcorders, cellular phones... even two at once with dual outputs.

Discover what so many other hams have already discovered: the ultimate solution for long lasting H-T power.

Notes from FN42

I have received a request for information about Romania, but I have none. Do any of you have news you could send me?

This month's column includes excerpts from five letters from the USSR, which certainly shows the opening of communications to the rest of the world from there.

Dave Horsfall submits his first offering from the land "Down Under." Much food for thought.

I would like to add my wishes to all for the religious season that is upon us, with peace and prosperity for all. Happy Holidays!

And last but almost foremost, I wish to thank Rod Hallen for his faithful reporting from Kenya during the past years. His news is always timely and informative. Best wishes in his move, and I certainly hope that he is able to acquire a license to operate in Pakistan. I am printing a letter from him in the column. Rod, I will certainly be glad to continue you as the new Hambassador to Pakistan. Think it over.—Arnie

N1BAC Roundup

USSR *From Vlad Zaytsev UA4FDS:* In April 1991 Paul UA4FEG and I began planning our second DXpedition within a year. We had operated from UH8W, UH8Y, and UI8U in early 1991 as UA4FEG/. . . and UA4FDS/. . . . We gave serious thought to our next spot. We contacted UZ4FWD, who had been to Asia in 1989, in hopes of obtaining information on making arrangements to get to Uzbek and Turkoman. They gave us a description and a few words about that particular operation. We then prepared our equipment, which included: a new model radio, two amplifiers with modern tubes, a folding 10 meter tower, a 3-band home-brew yagi, cables, guy wires, autotransformer, etc., with a total weight of about 300 kg.

We hope to get to Asia in October for two weeks, operating CW and SSB from those oblasts on all bands except WARC. We hope that conditions will be good and we will get through to all the world.

Please QSL to UA4FDS—Vlad Zaytsev, P.O. Box 555, Penza 440061 USSR (CCCP), or UA4FEG—Paul Bogachev, P.O. Box 222, Penza 440011 USSR (CCCP). We are also good in the *1991 Call Book.* Please QSL with a self-addressed-envelope (SAE) and IRCs or US$.

From Yuri Funkner UL7LS: QSL information for RF6Q/UL7LS is Yuri V. Funkner, P.O. Box 1 Frunze 459411, Ordzhonikidzevskiy rayon, Kustanayskaya oblast, Kazakh SSR USSR.

From Andrey V. Pervacov UA9XC: If you worked any stations from UA9X (UZ9X), Komi, SSR, U-obl:090 from 19 to 24 August 1991; or 4K3, Vaygach Isl., U-obl:114 from 20 August to 2 September 1991, or from Amderma, QSL direct or via P.O. Box 1247, 167001 Syktyvkar, USSR with an SASE. *[Andrey is the president of the Friends Radio Society.]*

From Alex Ulyanich RB5IJ: A new, comprehensive, English-language publication, *Soviet Ham Press Digest,* became available during the summer of 1991. The *Digest,* or *SHPD,* covers all aspects of the exciting world of Soviet amateur radio, and is aimed at amateurs around the world. Topics include ham life in the USSR, DXpeditions, clubs, awards, QSL information, contesting, equipment, and more.

SHPD, edited by Alex Ulyanich, is published by the Prometheus Amateur Association (PAA) of the Ukraine. Letters, articles, pictures, etc. should be submitted directly to the editor.

Subscriptions are available for US$12 and your callsign, name, and address, from PAA, c/o George Yankopolus NA3O, 13 Glen Meadow Drive, Glen Mills PA 19342. Up-to-the-minute member and DXpedition lists are available for IRCs/SASE from PAA, Box 195, 340000 USSR, or to NA3O. It is suggested that applications for membership (one-year US$10 and life US$50), award programs, and fees go to NA3O. *[We received a copy of the first edition, No. 1, August 1991, from Alex. It is 4 pages, 7 1/2 x 11 inches, translated from Russian to English, and appears to be very well done. The PAA also has an award program. I will upload the info to the 73 BBS under "Prometheus Award Program."—Arnie]*

From Sushkov Valery UA3GPA: Sushkov says that he has all addresses of the radioamateurs in the USSR and information about special callsigns, memorial calls, DXpeditions, and other information. If you are having trouble sending or obtaining QSLs, you may want to use his "Express QSL Service". Please SASE for more information to: Sushkov Valery, P.O. Box 3, Lipetsk, USSR, 398000.

INTERNET: dave@ips.OZ.AU

Hello from "down-under," or, as they say, "G'day." I'll be bringing you news of happenings in Australia, and I hope I can do as good a job as the late Ken Gott. By the way, it's nice to see that the USA has finally created a code-free licence—Australia has had one for almost forty years. Naturally the same gloom-and-doom predictions were made, and again when the Novice licence was introduced in the seventies, and again when Novices gained 2m FM privileges recently. . . . Amateurs certainly seem to be a gloomy lot!

Speaking of code-free licences, the debate is raging once again on the removal of the CW requirement for access to HF bands. The idea is to replace it with extra theory (packet radio perhaps?). Funny how it's mostly the code-free licence (6m and above) that seems to agitating for this! The packet radio system was full of messages on this subject. A lot of people appear to be unaware of the international radio regulations in this respect, although it won't be long before Morse code ceases to be used by the Maritime Service. Whither CW then?

Another battle being fought is the perennial packet protocol wars, this time ROSE vs. NET/ROM. Although NET/ROM is not permitted at the data link layer (due to what some would regard as restrictive Government regulations), it is allowable at level three, and appears poised to defeat ROSE. Given a country the size of Australia where nodes come and go (especially when they get stolen!), the dynamic routing capabilities of NET/ROM makes a lot of sense. As is becoming usual in amateur radio, there is a lot of in-fighting going on, and by the time this appears in print there may be some developments. Indeed, there are rumours that NET/ROM at level two will eventually be allowed, and some hardy souls are already using it. . . . The general feeling is that the government should not ordain how packets travel from point A to point B.

The Wireless Institute of Australia (WIA) has now become the sole supplier of examination papers to accredited examiners around the country. Previously, these examiners composed their own papers and submitted them for approval to the Department of Transportation and Communications (DoTC). This system was beset with various difficulties, with many unsuitable examination papers being rejected, and eventually the DoTC invited the WIA to become the sole supplier. Naturally, this upset a number of people, with all sorts of ludicrous claims being made, such as that the WIA was trying to make money from the system! Hands up, those VEs who are making money from examinations . . . This will take effect from next year, and is being phased in from October. It remains to be seen whether it works or not, but the "debate," if that is not too strong a word, is raging.

Cheers for now.

Brazilian QSL Bureau Update! According to the Brazilian Radioamateur League's statutes, delivering QSLs for all associates is one of the league's responsibilities.

In Brazil, a country with continental dimensions, our League has as many branches as states, and now and then, as every other year a new Directory is elected, no one can help eventual misunderstandings and collapsing here and there, hitting points that ought never be touched.

Something like that has hit exactly such an important point: the delivery of QSLs to the DX Bureau suffered during the last year, and we had to put an end to this disaster!

Unfortunately, the words about this were spread everywhere, radioamateurs from Brazil and DX were having troubles with the movement of their QSLs.

Something had to be done. The present President and Vice President of Radioamateurs League in Brazil had a very serious meeting with the EBCT (Brazilian Post Office Enterprise) main authorities.

An agreement was settled granting LABRE special post taxes, 40% lower than usual, a guarantee to the perfect development of these invoices by the Brazilian Radioamateurs League, the real importance of radioamateur being recognized. And in very special deference to all radioamateurs, the EBCT is delivering, by its own, more than one ton of QSL cards still in Brazilia at that time, as a show of what all radioamateurs represent to worldwide communications.

The troubles are over. We congratulate both the EBCT Brazilian Post Office Enterprise and LABRE, Brazilian Radioamateurs League, for this agreement towards the development of friendship, culture, understanding, communication, and goodwill among people of the world.

And to our DX friends, this agreement is surely news, as many of you still need Brazilian QSLs tor awards and files just as we too need the DX QSLs for our awards and files.

Ham Radio in a Marathon! It seems for the first time in the world, as far as we know, a radio amateur joined a Marathon, running more than 42 kilometers, handling and operating a VHF radio, tied to an HF radio through a repeater.

This past June, Sunday the 23rd, Paulo Roberto Domingos Sobrinho PY1ZT, operating with a special callsign of ZY1ZT, left the starting point at Leme Beach in Rio to run the International RIO Marathon, aiming at this "for the first time in the world" title!

Paulo used an Icom IC-2SAT linked to the LABRE's office through a VHF repeater on 147.300 MHz on a mountain near Niteroi City. PY1SCR operated the LABRE Kenwood TS-430S, handling calls to Paulo and trying to keep the battery usage down on the HT.

Even though many problems surfaced during the run (dead batteries and frayed mike cord, fixed with Paulo's teeth while still running), Paulo made 42 contacts on 2m, 40m, 20m, 15m, and 10m.

This year close to 3,000 athletes

Photo A. Paulo PY1ZT crosses the finish line, having made 42 QSOs en route on his IC-2SAT.

Photo B. Members of the Radio Society of Kenya who have worked the Russian satellites listed on the banner in the background.

were running the marathon, and we hope that next year even more will join us for this marvelous event, and who knows, maybe Paulo will break his own record for QSOs made during the 1991 RIO Marathon! After all, running 42.195 km while holding and operating radio equipment to the world deserves respect and admiration from all. Does the editor of the Guiness Book of Records know about PY1ZT and his success? Maybe we need to find out.

By the way, Paulo PY1ZT was ZYØSA at St. Peter/St. Paul DXpedition to the Rocks February/March 1989, together with Ron ZYØSB (PY1BVY).

The Callsign Game. Congratulations to Yosef Lior (ex-4Z9BFB), now 4Z5AA, of Timrat in the Galilee, who holds the distinction of opening up the new block of 4Z5 callsigns.

For some time we were wondering what new prefix would follow in the wake of the completion of the 4X6 series. From 1948 to 1966 the series from 4X4AA through ZZ was issued. Then up til 1988, the 4Z4 block was filled. More than a year ago, the last of the 4X6s, 4X6ZZ, was assigned. Then we started waiting.

Callsign assignment policy was once simplicity in itself. All two-letter suffixes were assigned in alphabetical order, with the Novices having an "N" tacked on which would be deleted upon passing the test for Grade B or Grade A. No old calls were re-issued, and you could tell who was licensed when, according to their call.

In 1987 policy changed, as the Ministry of Communications decided to give Grade A's (Advanced-Extra, approximately) the distinct 4X1 (and later 4Z1) prefix. Their old call could be re-issued to a family member passing the Grade B test. It is said that a few Grade A old-timers, fond of their old 4X4 or 4Z4 calls, refused to be pressured to take on the new "prize" prefix. It still remains to be seen what came out of these few hassles.

Following along with class-distinct callsigns, all Novices became 4Z9s with a three-letter suffix. Upon upgrading, they would be granted an entirely new call.

In the last year, previously unheard from 4X4 calls began appearing on the bands, whose youthful voices revealed that the Ministry had decided to do away with the "holes" in the callbook and issue the unheld calls to new licensees. Your faithful servant resigned himself to the apparent reality of no new prefix for much time to come, as among the 4X4s, 6's, and 4Z4's, a total of 2,028 callsigns are possible, and we don't yet have nearly that many currently licensed hams, not to mention the Grade A's and C's of other prefix distinction!

Unexpectedly, it came to our attention recently that 4Z5AA of the Galilee has inaugurated the long-awaited new series. Prefix hunters the world over—rejoice!

A New Israel Contest. The next Israel-International Contest is projected to take place on April 18, 1992. The rules will be published in our future issues *[if short enough]*. It will be a very interesting contest, with attractive prizes, and will be part of the special 100 hour Pesach activity of the IARC.

Refusing "Hitchhikers" Applying for IARC Membership Dani 4X4YM, chairman of the outgoing Israel Amateur Radio Club Membership Committee, said that there had been 150 new applications for membership in the IARC in the past year, yet only a third of them had been accepted. This curious state of affairs was explained, and later elaborated upon by Mr. Bar Sela of the Ministry of Communications. It turns out that in order to legally purchase a VHF/UHF scanner receiver, the Ministry of Communications requires that the applicant have either journalist's credentials or be a member of the IARC. Thus many people interested in no more than listening to police calls and cellular telephone conversations have been knocking at our door. The policy of the membership committee has been to prefer accepting only those with a real interest in amateur radio, rather than bolstering the club treasury with an additional 8,000 shekels (US$4,236) from those without an interest.

KENYA

Rod Hallen 5Z4BH
Box 55A
APO New York 09675

I've just returned from a mini-DXpedition to the Comoros Islands. I am D68RH down there. I had so much fun that I am planning to go back for the CQ WW Phone Contest the end of October. My tour in Kenya is up in December and I will be moving to Karachi, Pakistan. I've already written to a number of hams there but have received no response yet about licensing. I gather it will be difficult if not impossible to get a license. It will be a dreary two years if that is true.

The enclosed photo is of some members of the Radio Society of Kenya (RSK) who have worked the Russian satellites listed on the banner in the background. The gentleman whose picture is hanging above the blackboard is Daniel Arap Moi, the President of Kenya. The RSK has almost 100 members, but less than a dozen are truly active DXers.

73 from Kenya, Rod 5Z4BH, KB7NK, UK1HR, D68RH. *[We are certainly going to miss Rod's reporting on the goings-on in Kenya and the surrounding area.—Arniel]* 73

Jet-Powered ATV!

Ever wonder what it'd be like to fly a fighter jet? Wouldn't it be great to zip along at treetop level at several hundred miles per hour, buzz the airport in a high speed pass, or experience the thrill of aerial acrobatics?

Of course, it'd be even better if we could somehow experience all this right in our hamshacks without having to subject ourselves to high-G maneuvers. Well, Bill Wagner WB1ADF and Bill Kinton NX1D have worked out just such a system.

Vampire Mobile

Every year, in late September, the New England Escradrille group puts on the Warbirds Air Show at the Manchester, New Hampshire, airport. This is a chance for collectors and restorers of vintage military aircraft to show off their prize aircraft. One of the fighters that would perform during the show was a British training jet called the Vampire. It was manufactured during the '50s and is still in use in parts of the world. One of the interesting features of the Vampire is that it had a small glass porthole directly in the nose cone. A movie camera was usually mounted just behind the porthole and used during combat or training for reconnaissance, or to record the success of a mission. It seemed like the ideal place for a video camera!

Bill WB1ADF and Bill NX1D contacted Ed Stead of Stead Aviation (the owner of the jet) and proposed a way that spectators could ride along with the jet during its flight via an ATV link back to a TV receiver on the ground. Ed thought it was a great idea, and the ATV jet project was ready to take off.

The Remote-Control ATV System

Once the movie camera system is removed, there is a lot of room under the cowling of the jet for an ATV sys-

Photo C. The ATV package fits nicely in the nose cone of the jet. The camcorder looks through the gun camera porthole. (L to R:) Bill Wagner WB1ADF, Bill Kinton NX1D and pilot Doug Wood.

Photo D. Close-up view of the ATV installation. The P C. Electronics TC70-1 was remotely controlled by touch-tone commands received by a small HT underneath the transmitter. An 8mm Ricoh camcorder not only provided the video signal for the ATV transmitter, but also recorded the flight on its video tape.

Photo A. The Vampire ATV jet takes off during the Warbirds airshow. Photo by Charles R. Cole.

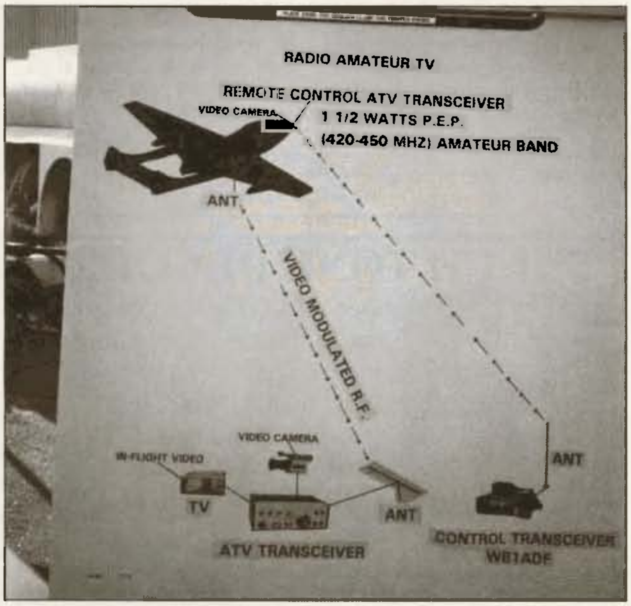

Photo B. The remote control ATV jet system. Chart drawn by Bill Wagner WB1ADF.

tem. Special care had to be taken to ensure that the ATV transceiver (P.C. Electronics TC70-1) and the Ricoh 8mm camcorder were securely mounted. Bill NX1D built up a touchtone decoder circuit and modified the TC70 so that they could remotely turn the transmitter on and off via a VHF link. Also, he had the ability to select more than one video source (in the future they may have a cockpit camera looking over the pilot's shoulder). They originally planned on a 100-watt amplifier but weren't able to cure some power supply problems before the show. The amplifier could also be turned on or off via touch-tone commands.

Since they had a 2 meter uplink, they could use the subcarrier of the ATV transmitter to operate as the output of a crossband voice repeater.

Loops and Rolls

Pilot Doug Wood took up the Vampire on several test flights prior to the scheduled show activities. It was a blast watching him do loops and rolls (without getting TOO dizzy!). Since they had an outside vertical antenna on the belly of the jet, the 1-watt ATV signal did quite well. ATVers as far away as the Boston area (40 miles to the south) had good reception at times, depending on the jet's altitude. A number of the ECAT (East Coast ATV Society) group could also watch the flight via the KA1AFE ATV repeater.

During the airshow, Bill WB1ADF and Bill NX1D had their receive station set up in the back of a Jeep next to a number of display booths. During the jet's flight, quite a crowd of fascinated spectators gathered around, glued to the spectacular views coming down from the ATV system. It was definitely a big hit with the crowd. Believe me, it takes something really intriguing to distract folks from watching passing planes at an airshow! The views from the jet were nothing short of amazing, particularly the high speed passes over the airport. After watching the jet video

Photo E. Bill Wagner WB1ADF mans the ground station during the flight, as fascinated onlookers gather about to watch the fantastic views from the jet.

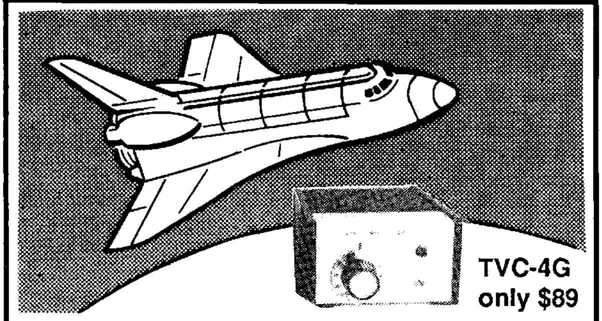
during its takeoff, acrobatics and landing, the crowd all felt as if they had gone along for the ride.

The Next Flight

Look for future flights of the ATV jet. Their next effort may include multiple camera views from the cockpit as well as the nose cone. Also, their 100-watt amplifier system should be in operation for some real DX reception of the jet.

Next month we'll show you the hardware details of the ATV jet system and how you can remotely control your ATV transceiver by touch-tone command. 73

AMATEUR TELEVISION



SEE THE SPACE SHUTTLE VIDEO

Many ATV repeaters and individuals are retransmitting Space Shuttle Video & Audio from their TVRO's tuned to Satcom F2-R transponder 13. Others may be retransmitting weather radar during significant storms. If it is being done in your area on 70 CM - check page 413 in the 91-92 ARRL Repeater Directory or call us, ATV repeaters are springing up all over - all you need is one of the TVC-4G ATV 420-450 MHz downconveters, add any TV set to ch 2, 3 or 4 and a 70 CM antenna. We also have downconverters and antennas for the 900 and 1200 MHz amateur bands. In fact we are your one stop for all your ATV needs and info. Hams, call for our complete ATV catalog - antennas, transceivers, amplifiers. We ship most items within 24 hours after you call.

UPDATES

Number 17 on your Feedback card

The Mini-Keyer

Refer to the article, "The Mini-Keyer," by Klaus Spies WB9YBM in the May 1991 issue, page 14. The following corrections need to be made for proper operation:

1. A wire is missing from the schematic (see Figure 1 for the updated schematic). The junction of D2 and C3 needs to be connected to pin 7 of U2b. You need to run an additional jumper wire on the PC board to make this new connection as shown in Figure 3. For your information, the combinations of C3/R3 and C2/R2 are contact debouncers for the dash and dot paddle inputs respectively. For dash generation, the U2b flip-flop must receive its clocking input from the output of the U2a flip-flop. When the dash paddle is closed, 5 volts is fed from pin 7 of U2b, through diode D2, to pin 14 of U2a which causes U2a to toggle its output, thereby producing a clock for U2b.

2. Two changes need to be made to the PC board foil pattern: Pin 6 of U2 should be connected to pin 10 of U2. The foil pattern erroneously shows pin 6 tied to pin 11. In addition, pins 3, 2, 10 and 6 of U2 need to be tied to +5 volts as shown in the schematic. If you have already made up a PC board from the original article just cut the trace leading from pin 6 of U2 where it joins pin 11 and attach it with a small jumper or solder bridge to pin 10 instead. Then solder pin 2 of U2 with a small jumper or solder bridge to the +5 volt trace that passes next to pin 2. See Figure 2 for the correct PC foil pattern.

3. Improvements: U3 is shown as a 7432 on the schematic, but is listed as a 74HC32 in the parts list. The circuit is appropriate for a 7432 (TTL) part. If a 74HC32 (High Current CMOS) part is used instead, the C2/R2 values may be modified for much lower power requirements. R2 causes an 8 mA load on the output (pin 3) of U3 as originally shown. If R2 is increased to 4.7k and C2 decreased to 0.005 µF, the RC time constant is maintained but a much lower current drain results. The same values may be substituted for R3/C3 as well. If you want to experiment around, you may be able to increase the value of R2 by two orders of magnitude and still retain proper operation. One final note: You can reduce the current consumption substantially by removing the LED indicator. *[Thanks to Dom Suppappola KA1VCR for this information.]* 73

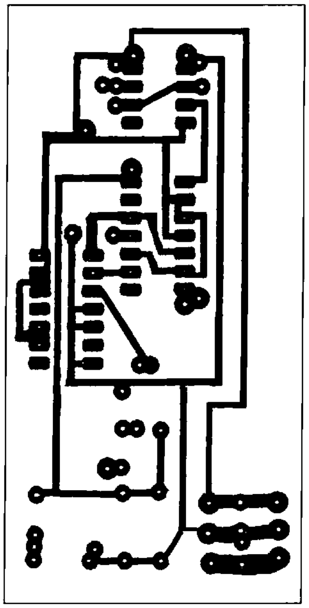

Figure 2. The corrected PC board foil pattern for the keyer.

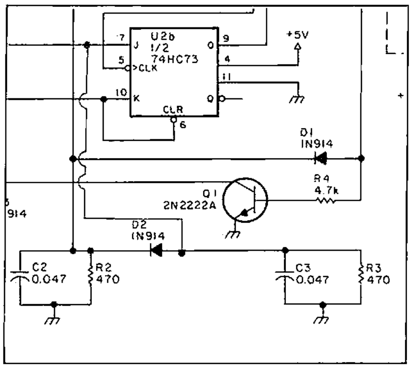

Figure 1. The corrected schematic (new connection shown in red) of the Mini-Keyer.

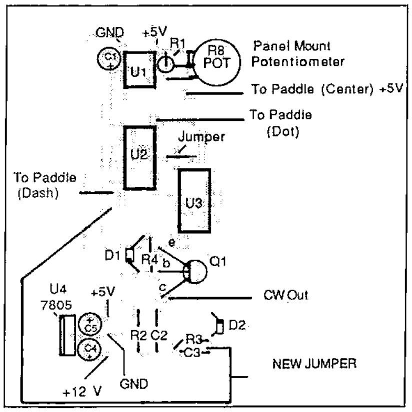

Figure 3. Location of the new jumper wire (shown in red) for the Mini-Keyer.

Fullerton CA 92633

RDF Spans the Globe

Writing for *73 Amateur Radio Today* is great fun because you are contacted by enthusiastic readers near and far. In the last two weeks, I received inquiries on radio direction finding (RDF) from South Africa, Germany and Zimbabwe.

It takes personal initiative to get a ham license. You need persistence to study and take exams for upgrades. So, it's no surprise that hams everywhere have a penchant for self-improvement and friendly competition in all forms. Thus, we challenge ourselves to succeed in on-the-air contests, chasing certificates, and breaking VHF/UHF distance records.

Regular "Homing In" readers know that another way hams compete is RDF contesting, often called "foxhunting" or "T-hunting." One ham goes to a special place he's found. Usually it's either hard to find or it has unusual radio propagation to the starting point, where the rest of the participants begin. They will see who wins by getting to the hider first, or perhaps by having the least mileage.

With our love of mobility and inexpensive fuel prices (compared to the rest of the world), it makes sense that hams in the USA would choose mobile over on-foot foxhunts most of the time.

Stateside hunts are local events (no national championship here yet), and rules and customs vary widely. They range from short "first-in wins" events, covering only a few square miles, all the way up to rough-and-tumble marathons where almost anything goes. On the Southern California "All Day" hunt, for example, the boundaries are the continental USA! Of course, you can't get a reliable signal across the country on 2 meters (space shuttle astronauts can't be the hiders), but ending points have frequently been in adjacent states. Once, the hiders were on a mountain over 250 miles from the start.

European Athletes

RDF as a sport in Europe began over 50 years ago, and swept the continent in the '50s and '60s. Enthusiasts soon realized that formal tournaments added to the fun. The first official European Foxhunt Championship Competition was held in 1961, with eight countries represented. It was so successful that it grew into the International Amateur Radio Union Region 1 Amateur RDF (ARDF) Championships, usually held every two years.

Though contestants of any age are welcome, young people usually dominate the winners' positions. They aren't all licensed hams. Only the transmitter operators must have their tickets, so SWLs can and do compete. They must know a little CW, because that is how the transmitters are identified.

Five foxes transmit in sequence, and the hunters must find them in order. It's a map and compass exercise as well as an RDF test. To win, you have to keep track of your own position, and the bearings to the five beacons, at all times.

Many young people have discovered foxhunting from Scouting. At a Boy Scout World Jamboree in Norway, 150 receivers and another 150 kits were produced to give 2,800 participants from 90 countries a chance at "hands on" RDF.

Another major source of European competitors is the military. RDF teams of soldiers and reservists are common. In earlier years, hunts were on 3.5 MHz. Eighty meters is being steadily replaced by 2 meters as the most popular band for cross-country transmitter tracking.

Well-attended Region 1 championships would not be possible without widespread local activity. Many clubs are active in ARDF. Foxhunters like to home-brew their gear, and new designs continue to pop up (see Photo A).

Russian Radiosports

Exposure to technology and physical exercise are both important for young minds and bodies. That is why foxhunting is encouraged in the Soviet Union, especially for teenagers and pre-teens. School radio clubs are common. HF and VHF transmitting and receiving equipment is often hard to come by, and must be made on site. But RDF gear is rolling off a Russian assembly line.

US hams who attended the 1989 Friendship Radio Games in Khabarovsk reported that RDF sets were the only commercially manufactured ham equipment they saw while in Russia. The Barnaul Radio Factory in southwestern Siberia produces toys and electronic products. Flip through the factory's 18-page color catalog, and the first two products you'll see are hand-held RDF sets.

The Altai-145 2 meter sniffer (Photo B) is a complete receiver/antenna unit in one piece, except for headphones. The receiver is built into the boom of a 3-element yagi. It's easy to use—the foxhunter holds it overhead and orients the yagi for loudest signal in the earphones, then heads in the indicated direction. For safety, the yagi elements are made of curved steel tape that folds over instead of impaling the operator or breaking.

Eighty-meter foxhunts remain popular in the USSR. The factory makes the Altai-3.5 for that band, with a similar tuneable receiver and attached loop/spike directional antenna system. The loop is about one foot in diameter. Barnaul makes only one other ham radio product, called a Tisa. It's a transverter to allow 10 meter rigs to transmit and receive on 2 meters.

The Barnaul Production Association is eager to sell its RDF products worldwide. While suitable for foxhunting in some other countries, the design is not compatible with the needs of T-hunters in the USA. The Altai-145 is meant to track CW transmitters and has approximately 7 microvolts sensitivity. US hams usually use FM and require a "hotter" front end. The VFO-tuneable (non-synthesized) Altai receiver is not stable or selective enough to work in the intense RF environment of most cities in the USA.

The Brits are Different

Englanders like foxhunting (both the radio and horseback hound-chasing kinds), but ARDF there is a world apart from events on the European continent. British hams hold their hunts on 160 meters, just as they have for about 70 years.

There are frequent local contests throughout the year, requiring entrants to find one to four transmitters in an afternoon or evening, with winners having the shortest elapsed time. Starters anticipate a drive of 10 miles or so to each fox, followed by a lengthy walk.

After some National Qualifying Rounds, the National Final Championship occurs each September. Three transmitters are hidden in well-spaced locations. They all provide a physical challenge, such as patches of nettles, swamps, and large decoy antennas that re-radiate the 160 meter signals.

The Radio Society of Great Britain heavily promotes RDF outings. RSGB is encouraging members to add 2 meters to local events, and is also setting up European-style hunts. The Society hopes that G-calls will someday be listed among the Region 1 championship winners.

High-Tech in Japan

Nowhere on earth is RDF competition more popular than in Japan, where it's often called "foxteering" or "foxtailing." Just as we have ATV societies

Continued on page 73

Photo A. Roel Bolt PA3CDO tests his experimental 3-element phased array for 2 meter RDF. He also built a companion portable superhet RDF receiver for the local competitions in Apeldoorn, The Netherlands. (Photo by WB6UZZ.)

Photo B. This RDF set for 2 meters is one of the few pieces of Amateur Radio gear being manufactured in Russia. Foxhunting is a regular activity for many school radio clubs there, for both SWLs and licensed hams.

9600 BPS Modems

Since the October column, I've received requests for more information about 9600 bit-per-second (bps) packet operation via the University of Surrey low-earth-orbit satellites UoSAT-OSCAR-14 and 22. The effort needed to get on these high speed packet satellites may seem formidable at first, but when the tasks are broken down into separate small projects, it's really quite simple to get a system on the air.

High speed packet activity at 9600 bps is not as common as 1200 bps, but is the only speed currently available from U-O-14 and 22. Radios sometimes require modifications to operate properly in both receive and transmit at this speed, and always need internal wiring additions to make the connection to appropriate high speed modems. This has stopped many potential enthusiasts from becoming active at faster data rates. Future radios will likely have data ports for these connections, but for now, it's necessary to make the changes on stock equipment which the designers never envisioned would be used for these purposes.

Small Projects

To prepare a station for activity at 9600 bps via satellite, there are several items that must be considered. U-O-14 and 22 operate via Mode J with a 2 meter uplink and 70cm downlink. U-O-14's FM uplink is on 145.875 MHz with an FM downlink of 435.070 MHz, while U-O-22 comes down on 435.120 MHz with the uplink on 145.900 MHz. A 9600 bps modem with TNC2-compatible packet controller, FM radios, antennas, a PC-compatible computer, and appropriate software are required to make connection with these bulletin board systems (BBSs) in the sky.

PacComm and TAPR Modems

The component at the heart of any UoSAT earth station is a high speed modem such as those available from PacComm and TAPR (The Tucson Amateur Packet Radio Corporation).

PacComm Packet Radio Systems, Inc., carries different versions of their NB-96 series 9600 bps modems ranging from cards for internal TNC-2 mounting to complete high speed, narrowband radios. For satellite work, either the MCNB-96 modem card for \$109.95, or the EMNB-96 external modem for \$174.95, is fine. The modem design was licensed from James Miller G3RUH and has been in production from PacComm for three years.

These products are not kits. They come complete with cables and instructions for interfacing to existing TNCs and computers. Details concerning the design and use of this modem can be found in James Miller's paper "9600 Baud Packet Radio Modem Design" in the "ARRL Amateur Radio 7th Computer Networking Conference Proceedings" dated October 1, 1988, available from the ARRL. PacComm can be reached at (800) 223-3511 or (813) 874-2980. Their address is 3652 W. Cypress Ave., Tampa FL 33607-4916.

The TAPR high speed modem by Steve Goode K9NG was originally designed for half-duplex operation. Details were outlined in Steve Goode's paper "Modifying the Hamtronics FM-5 for 9600 BPS Packet Operation" in the "ARRL Amateur Radio 4th Computer Networking Conference Proceedings" dated March 30, 1985, also available from the ARRL. A single modem will not provide the full-duplex ability needed for satellite activity. Since a complete kit, including double-sided board and all parts sells for \$35.00, it's cost effective to buy two to create one full-duplex modem.

One TAPR board can be wired as a MOdulator and the other as a DEModulator. The push-to-talk (PTT) line from the TNC does the job for satellite work, thus the original specialized modem PTT circuitry can be omitted on both boards. Clock signals from the TNC are routed to both boards, while transmit audio and receive signals are sent to the appropriate "MO" and "DEM" unit. Integration is simple and only one control, for transmit signal level, needs adjustment. This is set for three kHz FM deviation.

TAPR can be reached at (602) 749-9479, or write to: P.O. Box 12925, Tucson AZ 85732.

The TNC

The high speed 9600 bps modem needs a terminal node controller with a modem disconnect header. A list of U-O-14 users shows that most use variations of the TNC-2 design. In the U.S., many use PacComm TNCs with the NB-96 modem, while foreign U-O-14 enthusiasts have TNC-2s (or clones), with the original G3RUH modem sold by James as a "semi-kit" including a bare board, ROMs and documentation.

The modem disconnect header is the most important feature a TNC needs for 9600 bps use. This allows the internal TNC modem to be easily bypassed. Most TNCs have a disconnect header or a place on the main circuit board to install one. Modem documentation usually provides instructions for cutting one or two lands in the TNC when the external modem is attached.

A useful, but uncommon, feature in TNCs is a data rate to the computer greater than 9600 bps. Buffering problems are possible if both the TNC and computer are used at 9600 bps. Most TNCs are not wired to go faster, but with a few simple modifications, a TNC-2 can be configured for 19,200 bps operation.

The TNC-2 has several speeds for data transfer via the RS-232 jack from 300 to 9600 bps. The 300 bps dip switch setting is the least useful. To replace the function of the 300 bps switch with 19,200, first isolate pin 1 of SW2 from other lands on both sides of the circuit board. Reconnect pin 1 on SW2 to U1 (CMOS 4040) pin 10. If lands are cut to isolate pin 1 on SW2, be sure to reroute wiring that originally went through pin 1. Replace U3 (MC3403 quad operational amplifier) with a faster op amp such as the TL084. The TNC can now be used at 19,200 bps on the computer side when SW2 position 1 (previously 300 bps but now 19,200 bps) is selected.

Radios

A sensitive FM receiver capable of tuning increments of 2 kHz—to allow for Doppler shift tracking—should be used for the downlink. Most receivers have relatively narrow front-end filters

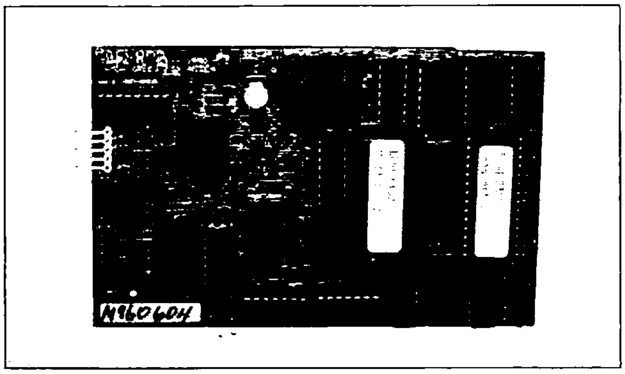

Photo A. PacComm High-Speed FSK modem for full-duplex 9600 bps.

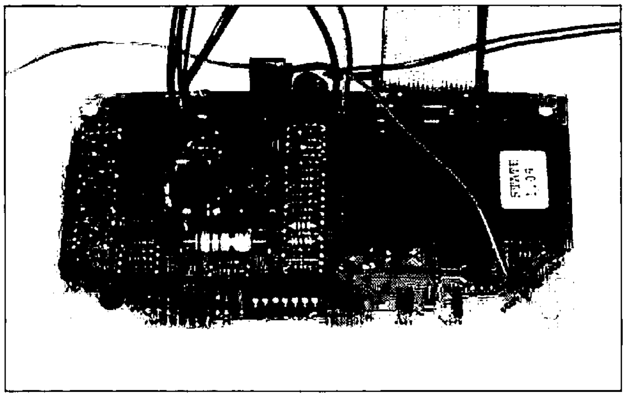

Photo B. K9NG/TAPR 9600 bps modem for half-duplex applications. Two of these modems provide full-duplex 9600 bps.

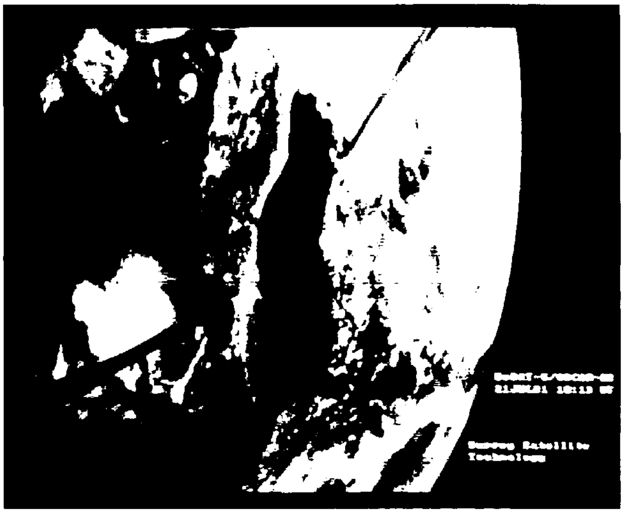

Photo C. A spectacular view from the camera on board U-O-22 as it passes over Italy.

since they're typically used only for voice reception. Although modifications can be made to widen the filters, usually requiring the replacement of a single filter unit, most will work fine without changes as long as the tuning can be adjusted during the course of a satellite pass.

The usual audio output from the receiver cannot be used due to the nature of high speed data. It's too wide for the radio's audio stages. Connection must be made directly to the output of the receiver's FM discriminator circuitry. *The ARRL Handbook* provides examples of what to look for when attempting to identify discriminator circuits.

For many newer transceivers and scanners, the connection is simple. An MC3357 (or similar) IC is used for the FM receiver. A shielded wire to pin 9 is all that is required. For older radios and those without this chip, a schematic search is in order. Generally, the discriminator output can be found just before the audio amplifier stages where two diodes, aimed in opposite directions and connected to a common point, are located.

John Branegan GM4IHJ wrote a very descriptive article, "Low Budget UoSAT-OSCAR 14 9600 Baud Reception" for the September 1990 issue of *The AMSAT Journal*. John described connection methods and bandwidth widening procedures for several radios. Preparing a receiver for 9600 bps reception can, in many cases, be very simple. When a good preamplifier is used in conjunction with a wide front end, tuning increments of five kHz are possible. A Yaesu FRG-9600 scanner works fine without changes and only a simple connection to the MC3357 and the addition of a preamp. The same is true for many other rigs.

A true FM 2 meter transmitter is required for the uplink. Phase-modulated rigs may be difficult or impossible to use without serious modifications. Frequency resolution should be at least 3 kHz, although many operators have done very well with rigs that tune in 5 kHz increments. The power output should be at least 10 watts.

The 2 meter transmitter must be properly connected to the modem. Finding the appropriate modulation input point and correctly setting the drive level are the most difficult portions of this task. The July 1991 issue of the *Packet Status Register* from TAPR contained a short article from James Miller titled "FT-736 and 9600 Baud Operation." James described how to find the varactor diode used in the Yaesu FT-736R 2 meter modulator, and how to drive it properly.

For nearly all transmitters, once the varactor diode has been found, the modem's transmit output signal can be coupled to the low-level, audio input side of the varactor, and adjusted via the modem's transmit-drive level potentiometer for proper operation. The PacComm unit is ready for connection when the drive point is found. The TAPR board should be connected to the radio through a 10 microfarad capacitor (already on the PacComm board). In transmit, the transmitter should be set for 3 kHz deviation.

Antennas

Most U-O-14 and U-O-22 users have directional arrays. This is not because the UoSAT activity demands high-gain arrays, but rather because the antennas are used for other satellite activities requiring large arrays. Very small yagis, home-brew dual-band J-Poles, small helix beams, and even omni-directional antennas have been used successfully for UoSAT work.

If high-gain antennas are used, remember that accurate tracking will be needed to keep the satellite in the useful beamwidth of the antenna. A typical pass may only last 20 minutes from horizon to horizon. If an automated antenna tracking system is not available, the operator will be typing, reading a satellite beam heading list, adjusting for Doppler, and positioning the rotators all at the same time.

Computers

The best software for UoSAT use was written for IBM PCs and their clones. The programs PB, PG, PHS and PFHADD are available free on many BBS systems and include complete documentation on their use. They are also available from AMSAT for a small fee. Write to AMSAT at 850 Sligo Ave. #600, Silver Spring, MD 20910 or call 1 (301) 589-6062 for details.

PB sets the TNC to KISS mode and allows reception of broadcast files from the satellites. It can also be used to begin file broadcasts and fill holes in received files that have been heard but not completely received and stored on disk.

PG provides complete connected uplink and downlink activity with the satellite while PFHADD prepares files for uploading and PHS processes received files for viewing and use.

Hundreds of text, data, picture and voice files have been sent through U-O-14, while dozens of picture files have been made available through U-O-22 in conjunction with its on-board camera experiment.

Try It

Since the launch of U-O-22, many new callsigns have appeared on U-O-14 and U-O-22. Although U-O-14 has been in orbit for nearly two years, this satellite is attracting attention now due to the camera system on U-O-22 (see Photo C for a spectacular view of Italy from this satellite). Hams have discovered the versatility of an international BBS in orbit that can send and receive files of all types at a speed eight times faster than the usual terrestrial system.

Start simple. Get a receive system operational on 70cm and add transmit capability later. Work on enhancements like faster computer-to-TNC data rates and receiver bandwidth widening when the time and money are available. Join the pioneers on the cutting edge of amateur satellite technology.

here is the next generation Repeater

MARK 4CR

The **only** repeaters and controllers with REAL SPEECH!

No other repeaters or controllers match Mark 4 in capability and features. That's why Mark 4 is the performance leader at amateur and commercial repeater sites around the world. Only Mark 4 gives you Message Master™ real speech • voice readout of received signal strength, deviation, and frequency error • 4-channel receiver voting • clock time announcements and function control • 7-helical filter receiver • extensive phone patch functions. Unlike others, Mark 4 even includes power supply and a handsome cabinet.

Create messages just by talking. Speak any phrases or words in any languages or dialect and *your own voice* is stored instantly in solid-state memory. Perfect for emergency warnings, club news bulletins, and DX alerts. Create unique ID and tail messages, and the ultimate in a real speech user mailbox — only with a Mark 4.

Call or write for specifications on the repeater, controller, and receiver winners.

The "Cheap and Simple" Power Supply Revisited

Improved regulation for a classic power supply.

by Vern A. Weiss WA9VLK/GØNBZ

The year 1981 gave us our hostages back, our White House Gipper and our first space shuttle mission. It also gave us "Cheap and Simple, your basic 13.8 volt, 25-A power supply," published in the January 1981 issue of *73 Magazine*. This article described a 13.8 VDC (variable if you want), high-current supply capable of delivering 15, 25 or even more amperes. The circuit was certainly more than adequate for the likes of me, but for some of you, its 0.4 VDC drop at full load was unacceptable.

The other day when Gorbachev and I were on the phone discussing this no-code thing, he said to me, "Can we really get Hewlett-Packard regulation at bargain-basement prices?" I replied, "Probably not, but maybe we can come close." There are better voltage regulators around than the 7812, which is the one specified in the 1981 "Cheap and Simple" article. You have to go a long way to beat the LM317 or LM200H. But let's stick with the 7812 because it's very affordable and it's always available at the local Radio Shack.

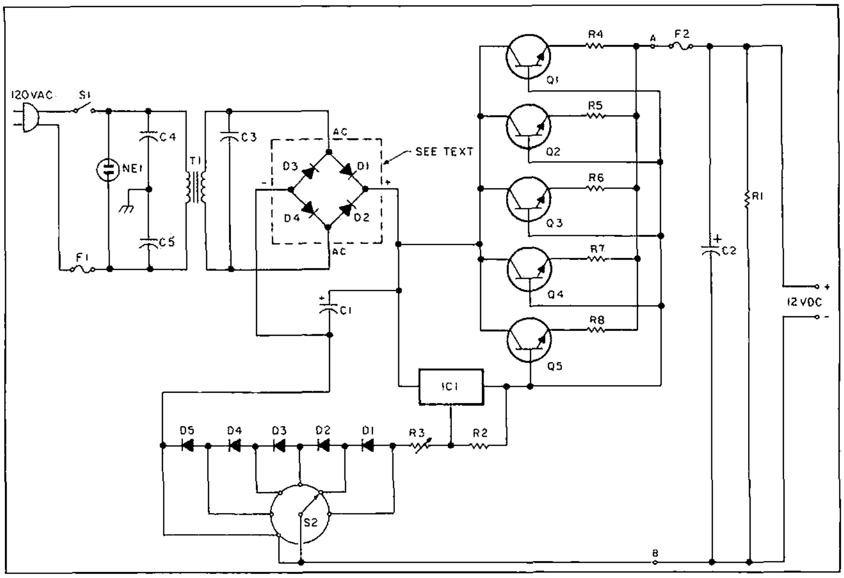

Figure 1. The original "Cheap and Simple" circuit as it appeared in the January 1981 73 Magazine article.

Revising the "Cheap and Simple"

Figure 1 shows the original "Cheap and Simple" circuit. Enjoy switch S2 and diodes D5, D4, D3, D2 and D1 while you have them because in the new circuit (Figure 2) they will be gone.

What we have done is simply establish output voltage feedback so that IC1 can compensate for voltage decreases under load. Monitoring the output voltage, as we have done, improves regulation. That will keep Daniel Ortega and other critics of my 0.4 VDC full-load drop happy.

Another hint for builders of this supply is to switch capacitors C1 and C2. The January 1981 article's "Parts List" showed C1 as a 13,000μF, 25V electrolytic and C2 as a 10μF, 25V electrolytic. The parts list should have shown C1 at 10μF and C2 at 13,000μF. If you followed the text, your project probably went smoothly, but if you relied too heavily on the parts list (and, I admit, I am as guilty of this as the next guy), your capacitors may have become impossible to get along with.

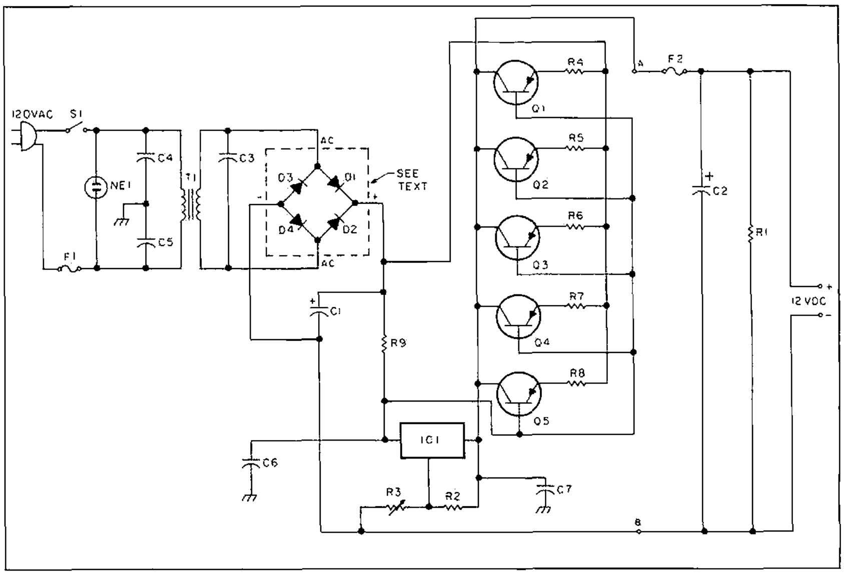

Figure 2. The modified power supply circuit monitors the output voltage, thus improving voltage regulation.

Component parameters can differ greatly between companies, especially when we start comparing a new component with one that has been stored beneath the septic tank since 1960. If your supply isn't performing like you think it should, and you've followed my suggestions to a tee, try **NOT** following them to a tee. Experiment with other components of similar values. I would not, however, actually imply that you should use **NEW** components, fresh and within manufacturer's tolerances. That approach gets into money that defeats the purpose of "Cheap and Simple." We are ham operators, remember, and pride ourselves in building anything electrical from common items found easily in any household in America. 73

Contact Vern A. Weiss WA9VLK/G0NBZ at 4259 Park Place, R.R. #5, Lakes of Four Seasons IN 46307.

Revised Parts List

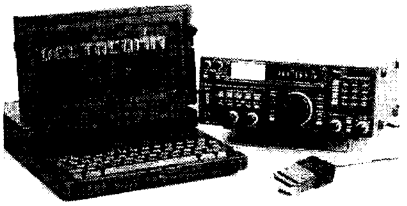
C1	10µF, 25V electrolytic capacitor
C2	13,000µF, 25V electrolytic capacitor
C3	0.22µF, 100V tubular capacitor
C4, C5	0.01µF, 500V ceramic capacitor
C6, C7	0.1µF ceramic capacitor
D1–D4	25 amp diodes or bridge rectifier
F1	5 amp fuse
F2	30 amp fuse
Q1–Q5	2N3055 transistors (mount on large heatsink)
R1	120Ω, 4W resistor
R2	220Ω, 1W resistor
R3	5k Ω, 2W resistor
R4–R8	0.25Ω, 1W resistor
R9	6.2Ω, 1W resistor
IC1	7812 voltage regulator
S1	SPST switch
T1	120/17–24 VAC power transformer (NOTE: must be able to handle full current)

Miscellaneous: NE1 neon bulb, binding posts, line cord, 0-25 VDC voltmeter, 0–30 amp ammeter, heat sinks, chassis, blower, fuseholders, and bulb socket.

ICOM™ R7000 SWEEPING 1300 CHANNELS/MIN.

DELTACOMM™ I-7000 and your MS-DOS computer gives you a custom interface integrated with optimized software that will not just control but will maximize the potential of your R7000.

- Spectrum log at speeds in excess of 1300 channels/min while automatically generating a histogram of frequency activity.



- CYBERSCAN™ allows scan file tracking control of systems employing frequency hopping techniques.
- Birdie log during frequency search automatically characterizes your R7000, then locks out those frequencies during frequency search operation.
- Custom interface has electronics to allow software control (by channel number) of external tape recorder.

ICOM™ R71 RECEIVER COMMUNICATIONS MANAGER

DELTACOMM™ I-71 Version 4.0 offers read/write control of your R71 receiver's frequency, mode and memory channels. Additional program features include auto log frequency search, scanning, timer/clock event management, data base management, pull-down menu windows, split screen for your Terminal Node Controller (TNC) communication needs and the ability to control an antenna switching system or logging tape recorder.

- Data base management allows definition of frequency, call sign, time schedule, mode, target area, country, 140 character notes field, 69 character TNC command field, QSL status, control relay status and, in addition, displays user defined optimum settings of receiver front panel knob positions.
- Combined with your TNC, DELTACOMM™ I-71's user defined command codes program your TNC for reception and logging of PACKET, AMTOR, RTTY and Morse Code (fully unattended and automatically).

16-DIGIT TOUCH-TONE™ REPEATER PROGRAMMER

DELTATONE™ 2.0 connects to your MS-DOS computer via the printer port. In its high speed mode, DTMF digits are sent to your repeater controller at a rate in excess of 500 per minute.

- DELTATONE™ 2.0 accepts programming commands from a file created using your favorite word processor.
- Transformer coupled 600 ohm balanced output, adjustable to -10dbm, and software control of relay contacts makes interfacing an easy four (4) wire connection to your transceiver, handheld or repeater controller.

All DELTACOMM™ communication products include custom interface, UL listed power supply and components for cabling.

DELTACOMM™ I-7000 or I-71 $299.00 each
(I-71 requires ICOM™ UX-14 converter)
DELTATONE™ 2.0 including interface $149.00

VISA, MC, AMEX and MO accepted. Contact us for discount pricing to registered DELTACOMM™ users.

MODEL 1410G MODEL 1450G

All amplifiers (non-rptr) are linear, all-mode with fully automatic T/R switching and PTT capability. The receive preamps use GaAs FET devices rated at .5 dB NF with +18 dBm 3rd order IP. LPA, Standard and HPA amps are intermittent duty design suitable for base and mobile operation. Repeater amps are continuous duty, class C.

Amplifier capabilities: High-power, narrow or wide-band; 100-200 MHz, 225-400 MHz, 1-2 GHz, Military (28V), Commercial, etc. – consult factory. A complete line of Rx preamps also available.

RX Preamplifiers

Band	Model	NF (dB)	Gain (dB)	Connector

KD8JN's QRP Achievements

If you have never taught a Novice class, you're missing out on a lot of fun. When I teach a class, we have a good time. That's the way it's suppose to be, right? The class learns all about deep earth antennas, dark emitting diodes, and feedlines long enough to reach from the antenna to the radio.

Now I guess you're wondering what this has to do with QRP. Well, one of the young men in my class turned out to be one hell of a QRPer and DXer. This month we'll take a peek inside the shack of Randy Phelps KD8JN (see the Photo).

Randy works on all bands and most modes, including RTTY and packet, although not necessarily with QRP. When the HF bands are running, you'll see Randy's TNC sending to the DX cluster NODE. In the shack you'll find a Heath SB-220 ready and willing to break through the pile-up to work a new DX station if need be.

However, the DX total with just the 2 watt Argonaut 515 is very impressive. Randy has over 202 stations worked and 164 stations confirmed. The skill needed to work, using a pea-shooter, side by side with the big guns, really paid off.

Randy took first place, single op, all-band U.S.A. 8th district place in the 1989 CQ World Wide DX contest in the QRP section. He also impressed the neighbors with his first place single op phone, Ohio section, in the 1989 ARRL DX International DX contest. Not bad considering the amount of RF power used was less than that required to run the PK-232!

QRP Antennas

Randy will be the first one to admit the need for a better-than-average antenna farm when running QRP and chasing DX. Randy's antenna installation would make any ham's want list. Nope, it's not comprised of three monoband beams placed a full wavelength apart. It's a TH6 DXX tribander in a city lot. Simple wire dipoles are used for 40 and 80 meters. What makes Randy's systems click is smoothing out all the rough edges.

I've discussed these before, here in the "QRP" column. All the antenna's hardware is stainless steel. Every PL-239 has a silver plated-Teflon™ insulated center. No hamfest cheapies here! The feedline, while just coming short of nitrogen-filled 7/8" hard-line, is the best you can buy. You'll find no "barrel" connectors in any of Randy's feedlines. There is only one RF power meter/SWR bridge in his shack. And finally, everything in the antenna farm is designed to be used at the maximum legal power.

As you can see, Randy is a very active ham. I'll get a call from him during the contests asking if I have a 5Y4GT. I can't let this one go, so I tell him, "No, but I think there's one in the junk box." Next time you hear Randy on the air, ask him if he has a 5Y4GT.

Photo A. Avid DXer and QRP enthusiast Randy Phelps KD8JN at his operating position.

Expanded Voltmeter

Several months ago I had a small circuit for expanding the range of a 0–50 µA meter to read 10–15 volts. It was a simple little circuit using a 10 volt zener diode and some resistors. This month I'll show you an expanded voltmeter that works even better.

Take a look at the schematic. The voltage reference this time is nothing more than an 8 volt regulator. An LM78L08, to be precise, and a resistive voltage divider. When coupled to a 0–50 µA meter, the range will be 10–15 volts. What makes this circuit a bit better is the ability to zero the meter at exactly 10.0 volts on one end, and 15.0 volts on the other end. When using only the 10 volt zener diode, sometimes the meter would not fall to 10 volts, when in fact the battery voltage is 10 volts.

The circuit may be built on a small perfboard or PC board. Make the board small enough to mount directly to the back of the meter. Use good quality parts for the meter; they will reflect higher accuracy.

To calibrate the expanded voltmeter, adjust the 1000 ohm trimmer so that the meter reads zero with 10 volts at the input. Raise the input to 15 volts and set the 20k trimmer for full scale (15 volts); you might want to re-check the setting by running through them a second time. Be sure to use a good, high quality digital voltmeter when setting up the circuit. With a good digital meter for reference, you'll have resolution down to 0.1 volt—or better.

I used a 0–1 mA meter in place of the 0–50 µA meter. Doing this, I had to change the value of the 56k resistor in the voltage divider. I had to drop the resistor's value to 4.7k to get the meter to operate correctly. With the 0-1 mA meter, the circuit draws 27 mA from the battery you're checking.

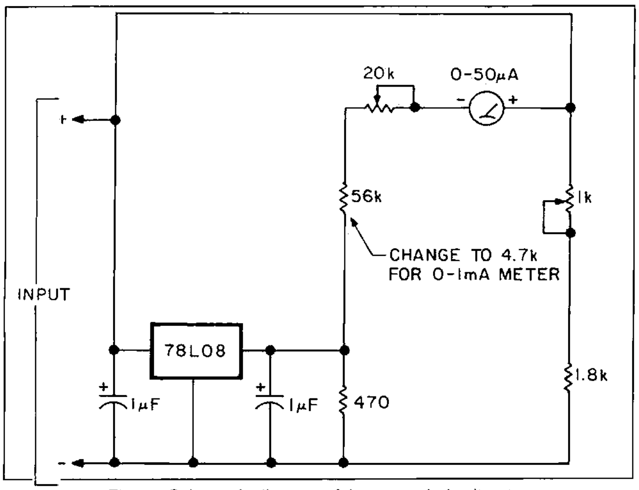

Figure. Schematic diagram of the expanded voltmeter.

That's all for this month. I still have some Pulse Charger kits left at $29.95 + $2.50 P/H. Great project to charge up those gelled lead-aid batteries for winter projects.

Getting deep into winter, home-brewing goes into full gear. Next month we'll look at Mike's Rules of Ten. 73

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
6 Jenny Lane
Baltimore MD 21208

Oops! It DOES Exist

How could I have been so blind? I mean, it was right there, under my nose. All I had to do was look for it! In the October 1991 "RTTY Loop" I mentioned that some amateurs were looking for interfacing for their Commodore computers on RTTY, and I said that the old Microlog stuff was great but no longer available. Was I wrong!

Thanks to Michel Ricard VE2DDT and others, my attention has been drawn to the advertisement on page 26 of the same issue of *73*. G and G Electronics of Maryland is just the answer for the amateur looking to put his or her Commodore computer onto the air.

The upshot of this is that I had a delightful conversation with Jeff Goldman, of G and G Electronics, who gave me some background on the situation. It seems that G and G was a dealer and service facility for Micrlog equipment, both companies being located in Gaithersburg, Maryland, a suburb of Washington, DC. Microlog decided to pursue other markets, and the amateur line was in danger of being orphaned. That's when G and G stepped in. With the original equipment and plans produced by Microlog, they have tooled up to continue to produce this line of amateur computer RTTY equipment.

The G and G line currently features five systems or devices, which can, among other things, put your VIC-20 or C-64 on the air as a receive-only unit, multimode transceiver, or intelligent terminal. The units are affordable, and represent quite a bang for the buck!

The Morse Coach

Here's a simple plug-in cartridge for the expansion port on a C-64 that enables a complete, computer controlled Morse teaching plan. In use by government agencies and military programs, this trainer is as useful for the individual as it is for club programs.

An "Alphabet" mode presumes no prior knowledge of Morse, and sends the characters at a minimum 10 wpm character rate, with variable spacing for the slower rates. This avoids the "dit counting" pitfall well known to instructors. (Uncle Wayne's tapes work the same way!) A "Practice" program sends a predetermined number of five character groups, with the student typing in the answers. After the run, a score is displayed. In the "Speed Test" routine, getting less than 80% correct aborts the test.

Both of these latter tests employ logic to allow for the characters to get "out of sync" by either missing a key or hitting a key twice. Lacking that, one miss could throw the entire test out of line.

Overall, the Morse Coach may be just the answer for individuals, clubs, or groups studying for a Morse code test.

The SWL Cartridge

By plugging this simple cartridge into your C-64 or C-128 expansion port, you can turn your computer into a RTTY and Morse receiver. All it needs is receiver audio, and the screen displays a real-time clock, mode and speed in use, and status indicators, along with the incoming text. Reception of five-level Baudot at 60, 66, 75, 100 and 132 wpm is supported, along with ASCII at 100 and 300 bauds, and Morse from five to 99 words per minute.

A video "cross" display is simulated for RTTY tuning and a red dot for Morse. Audio is piped through the TV speaker so that monitoring the band becomes an easy matter.

Along with the SWL Cartridge, an AIRDOS disk program is available, which allows saving the received data to disk. Printer output is provided to the standard computer printer, with either manual or keyword control. If receiving Morse or RTTY is your desire, this may be just the package.

ART-1 All-Mode Terminal

Here's a multi-mode controller that plugs into your C-64 or C-128 and provides a wide range of digital modes in a small package. The ART-1 features RTTY, ASCII, Morse, and AMTOR, in a box less than six by six inches big.

Physical connection to the C-64 or C-128 is via a cable to the user port. Radio input is via receiver audio, and transmit output may be positive voltage switching for CW and FSK, AFSK tones for microphone input, and PTT transmitter control. No power supply is required, all operating voltages being obtained from the host computer.

As with the SWL, operation on Morse at speeds up to 149 wpm, on RTTY at speeds from 60 wpm (45.45 bauds) to 132 wpm (100 bauds), and ASCII at the standard 110 and 300 bauds, is supported. Additionally, four AMTOR modes are supported: Mode A (CHIRP), Mode B (FEC), Collective/Selective Broadcast, and Listen Mode (eavesdrop Mode A).

With the same on-screen tuning cross or light, operation of this little wonder is straightforward and should provide years of flexible communication.

AIR-1 Cartridge

The preceding units were designed for the C-64 or C-128; here is one for the "lowly" VIC-20. The AIR-1 cartridge provides full RTTY, Morse, and AMTOR operation in a plug-in cartridge at a budget price.

Fitting directly into the computer's expansion port, this cartridge takes receiver audio and puts out positive and negative switched levels for RTTY and CW, plus AFSK tones for microphone keying. As with the others in the line, support for Morse to 149 wpm, Baudot from 60 wpm to 132 wpm, and ASCII at 110 or 300 bauds, is provided. AMTOR support is also available in the same four modes as the ART-1. A real-time clock, selective calling, WRU (who are you), and multiple transmit buffers make the AIR-1 a fully functional unit.

There is even a code practice routine built in, to send random five-character code groups at any programmed speed. A true RTTY demodulator is built in as well, handling the standard tone pairs of 2125/2295 Hz, with switch-selected mode or narrow shift.

AIRDISK

If you have a terminal unit and Commodore computer, the AIRDISK may be just what you're looking for. Containing the software of the AIR-1, but not the hardware, this program adds the all-mode capability of the AIR-1 to VIC-20 and C-64 computers for less than forty bucks.

As with the others, operation is on all modes, with the same spectrum as the AIR-1. On-screen tuning and software digital filtering makes operation on the bands a piece of cake. This program acts as a software interface between just about any terminal unit and your computer, allowing you to either use one you have, or experiment with new demodulator designs.

Both VIC-20 and C-64 programs are on the same disk, with the VIC-20 requiring at least 16K of RAM in the computer. For those C-64 users who do not want or have a disk, an AIR-ROM software cartridge is also available. If you have a demodulator you are happy with, this is certainly the most cost effective way to go.

Overall, we all need to thank G and G Electronics of Maryland for promoting the old Microlog line. Far too often in the amateur RTTY world we have seen wonderful equipment produced then discontinued as the manufacturer abandons the ham market. Several such units are sitting on my shelves now. Fine though they were, they were dead ends on the road of technological development. By continuing to support our market, G and G deserves our support in return. Thanks!

Next month I may have another program for the MS-DOS crowd with potent possibilities. In the meantime I look forward to hearing from you by mail or on CompuServe (ppn 75036, 2501), Delphi (username MARCWA3AJR), or now on America Online as well (screen name MarcL9). I'll tell you more about America Online in the future, too, don't worry!

Morse Coach	C-64	$ 49.95
SWL Cartridge	C-64/C-128	$ 69.95

Keys to Motivation

The theme of this month's column is *motivation*. There is probably no other factor that is more directly responsible for the success or failures we experience in life than that of motivation. It permeates and affects everything we do, but it is especially important for those of us who are teachers or instructors to understand the importance of motivation in the learning process. Someone once said, "The man who believes he can do something is probably right, and so is the man who believes he can't."

Those of us who stand in front of the classroom must never forget that the youngster or adult who is sitting before us needs a reason to be listening, a desire to learn, and a belief that he or she can master the material. All of us require motivation to master new skills and grow.

The teacher of a technical subject should be especially sensitive to the ability levels of the students, and be sure to present the curriculum in a way that is relevant to their needs.

A Quiz

Try to imagine how you would feel if a teacher were to give you just five minutes to translate and react to the following popular adages (see the answers at the end of the column):

1. Avian species of identical plumage congregate.
2. Freedom from encrustations of noxious substances is contiguous with conformity to divine prescription.
3. Pulchritude possesses solely cutaneous profundity.
4. A superannuated canine is immune to indoctrination to innovative maneuvers.
5. Ululate not over precipitated lacteal secretion.
6. All that coruscates with resplendence will not assay auriferous.
7. The existence of visible vapors from ignited carbonaceous materials confirms conflagration.
8. Mendicants are interdicted from elective recipiency.
9. Probity gratifies reflexively.
10. Inhabitants of vitreous edifices ill-advisedly catapult petrous projectiles.

If you're like most of us, you experienced frustration and anxiety while rushing in to translate the words a teacher told you to respond to. Every day, all across the country, children are sitting in classrooms feeling frustrated and anxious because they don't understand what's being said to them. It may be English that's being spoken, but it's not appropriate to the children's ages or abilities, and it's certainly not relevant to their lives.

Specific Points

Diana Ramsey, in her book *Keys to Motivation*, notes some research findings for teachers to keep in mind.

1. In order for a learner to take a risk in the learning environment, the learner must perceive that risk as being manageable.
2. The degree of risk present in a learning situation is uniquely perceived by each learner.
3. The teacher, as motivator, can create a classroom climate where risk-taking is part of the learning process. Exploration, growth, and learning result from students mastering challenges the teacher presents.
4. The #1 motivator is an opportunity for success.
5. Students learn best when they are fully involved and appropriately challenged. The teacher should initiate a rotation of challenge and success.
6. Learners must see a payoff for their efforts if motivation is to be maintained.
7. Both boredom and fear decrease student opportunities to learn. Fear and boredom are negative stresses, especially when they are sustained over a long period of time. Hence the phrases "bored to death" and "scared to death."

Dialogs with Self and Other

Positive affirmations are statements we should learn to use and encourage more often in our daily lives. They are especially important in the classroom. We all draw strength from many sources—a higher power, our parents, family, friends, and co-workers. A powerful source of strength we sometimes forget to use is our own personal power.

Positive affirmations are strong positive statements we make to others and ourselves, or hear others say. They help us tap our internal power and focus on the positive use of that power. The use of positive affirmations in the classroom can help students become self-motivated in their work efforts. It also helps build self-esteem and creates the feeling that we have power over events in our lives.

An example of a positive affirmation is, "I have all the information I need to answer these questions." It avoids the use of negative words like no, can't, don't, and won't, which tap negative energy rather than positive energy. Positive energy affirmations empower us by focusing on our strengths to manage our weaknesses.

Many successful people have revealed their ability to create a mental picture of success; this is helpful in creating a positive affirmation. Teachers who encourage the use of positive affirmations are going a long way towards ensuring that they will have a group of happy, successful, highly motivated students who are eager to come to class and will enjoy and benefit from the learning process.

Quiz Answers

1. Birds of a feather flock together.
2. Cleanliness is next to godliness.
3. Beauty is skin deep.
4. You can't teach an old dog new tricks.
5. Don't cry over spilled milk.
6. All that glitters is not gold.
7. Where there's smoke, there's fire.
8. Beggars can't be choosers.
9. Goodness is its own reward.
10. People who live in glass houses shouldn't throw stones. 73

Please send write-ups on interesting classes, recruiting ideas, youth club activities, or individual children's experiences along with photos, to Carole Perry at the above address.

Photo A. Good motivation is the key to happy, learning students. In the ham class as well as in the school classroom, be sure to provide an environment that encourages risk-taking and success.

Photo B. A good teacher makes sure every student has the opportunities for challenge and success.

and DX clubs in the USA, the JAs have organizations devoted to foxhunting.

Commercial RDF gear is plentiful and popular. Typical hand-held units for 2 meters feature a 2-element phased array beam, similar to the HB9CV array found in HF DX stations. This array is smaller than a yagi, which makes it excellent for romping through the brush.

The receiver, built into the short boom, is synthesized to cover 144 to 146 MHz. It detects both AM and FM, and is very sensitive. An S-meter and electronic attenuator are included, giving contestants the ability to estimate distance to the fox. One model features an audio S-meter in one channel of stereo headphones, and receiver audio in the other channel.

You ask, "Why aren't these state-of-the-art sets exported to the USA?" Good question—I'd like to know, too. With a slight modification, they would cover the full US 2 meter band. Perhaps US importers don't think that T-hunters here will buy enough of them to cover the high cost of FCC receiver certification. What do you think?

In addition to on-foot radio races, Japanese hams are discovering mobile T-hunts. World-class T-finder Yoshiko Yamagami JQ1LCW sent pictures of a June 1991 nighttime event. Yagis were the most popular RDF antennas (Photo C), with some ingenious methods of mounting and turning.

Yoshiko says her club holds a hunt every two months, with a two-hour time limit. It's common to see 20 to 30 vehicles competing. The Japanese are strong supporters of national and international events. The All-JA-DF competition for 1991 was held in October near Mt. Fuji. JA hams have participated in the Friendship Radio Games and the All-China RDF Contest.

Your Turn

What is your club doing about RDF, for sport or more serious purposes? Send me your T-hunt news and photos to share with "Homing In" readers. If your club's newsletter reports on T-hunting, how about putting me on the mailing list?

You say there is no hunting in your area? Well, your assignment for next month is to start one. Just talk it up and you will probably be surprised at the response.

Kevin Kelly N6QAB, an intrepid Southern California T-hunter, moved to Albuquerque some months back and found no radiosporting activity. After a bit of jawboning and demonstrating, an active hunting crew developed. You can now find a 2 meter mobile hunt there almost any weekend.

So now it's your turn. I expect a full report. ■

Amateur Software and Hardware for the Commodore User

ART-1

ART-1: A complete interface system for send and receive on CW, RTTY (Baudot & ASCII) and AMTOR, for use with the Commodore 64/128 computer. Operating program on disk included. **$199.00**

AIR-1

AIR-1: A complete interface system for send and receive on CW, RTTY (Baudot & ASCII) and AMTOR, for use with Commodore VIC-20. Operating program in ROM. **$99.95**

SWL

SWL: A receive only cartridge for CW, RTTY (Baudot & ASCII) for use with Commodore 64/128. Operating program in ROM. **$69.95**

AIRDISK

AIRDISK: An AIR-1 type operating program for use with your interface hardware. Both VIC-20 and C64/128 programs on one disk. **$39.95**

AIR-ROM: Cartridge version of AIRDISK for C64/128 only. **$59.95**

MORSE COACH

MORSE COACH: A complete teaching and testing program for learning the Morse code in a cartridge.

For C64 or C128. **$49.95**

Microwave PLL Bricks

It's the end of the year, and I'm thinking about all the projects I've done. Several of them are still in the mill for improvements, and, considering my basic personality, probably will be forever. I'm still working on the laser communications projects and improving my microwave station for 6 and 10 GHz. Recently they had to take a back seat to other items, particularly vacations and family matters which, of course, take priority.

This month we will wrap up phase-locked brick oscillators for some time, at least until a better device becomes available in surplus. The brick oscillator, in my estimation, is the best single local oscillator. It has promoted interest in microwave, as it is easy to modify to amateur frequencies by retuning the output filter. Once retuned, you have a high precision that's easy to maintain. Accuracy is something in the order of a few kHz at 10 GHz for a stand-alone unit. Long-term (a month or so) stability runs from 20 to 40 kHz.

Where do you get a brick? Check your local swap meets and flea markets. You never know when one might turn up. Keep an ear tuned for commercial stations closing down a microwave link. If you're in education, have your school write a letter to the communications authority for possible donations of material. It's worth a shot.

As to the applications the brick oscillator can fill, they are many. Use depends on what frequency brick you can obtain. If you can't locate one, I have a modest quantity of 6 and 10 GHz bricks. These include bricks without the harmonic multiplier assembly. This is the type needed for this month's project. All units I specify have been bench-tested and are functioning.

Constructing the Converter

Although the basic brick is used extensively for the 6 and 10 GHz amateur bands, I verified that it can cover other frequencies, including the 2304 MHz amateur and 1691 MHz weather satellite frequencies. While quite different in application, both frequencies present exciting new domains to explore. It is tough to locate surplus components for these frequencies. What came about was the realization that a 10 GHz brick can work on these frequencies, making it possible to more easily construct a 2304 MHz transverter and a receiver for the 1691 MHz weather satellite service.

The trick in making a converter is to come up with a simple mixer and RF amplifier. These are not difficult to obtain from standard designs published previously. The local oscillator is what stumps most people on home-construction projects. I would prefer a GaAsFET amplifier with a MGF-1402 device. The mixer is not too difficult to come up with. I designed a home-brew mixer for the 1.3 GHz bands which will also work well at 2.3 GHz. Packaged mixers, such as the Mini Circuits Labs TFM series mixers, are small and cost less than $20 each. Performance is good to 1.5 GHz, which is not bad for a mixer (TFM-5) that is so small you can hide it in a pencil eraser.

The RF amplifiers are not difficult to obtain, either. You can purchase several fully constructed devices. Several GaAsFET amps are available for home-brewing. The ARRL has published excellent designs from both Kent WA5VJB and AL WB5LUA. See Al Ward's article on designs for 2.3–10 GHz in the May 1989 issue of *QST*. Any *ARRL Handbook* from the last few years has some of Kent's GaAsFET designs for 1296 MHz. Look them up; they are what the doctor ordered, and they should be modifiable to work at 1691 MHz.

The main difference between the two converters (apart from frequency) is that the 2304 MHz converter is bi-directional. It will receive as well as transmit, with relay switching used to turn the preamplifier around for transmit. This amplifier will not deliver rock-crushing levels, but it will provide a good 10 to 15 dB gain from the mixer. See Figure 1 for block diagrams of both systems.

The Weather Receiver

The weather satellite converter output is connected directly to a 137 MHz VHF weather receiver. In the 2304 MHz version, the receive circuitry is essentially the same except for relay switching. In transmit, the transfer relay reverses the preamplifier to make it a transmit amplifier. An attenuator is switched

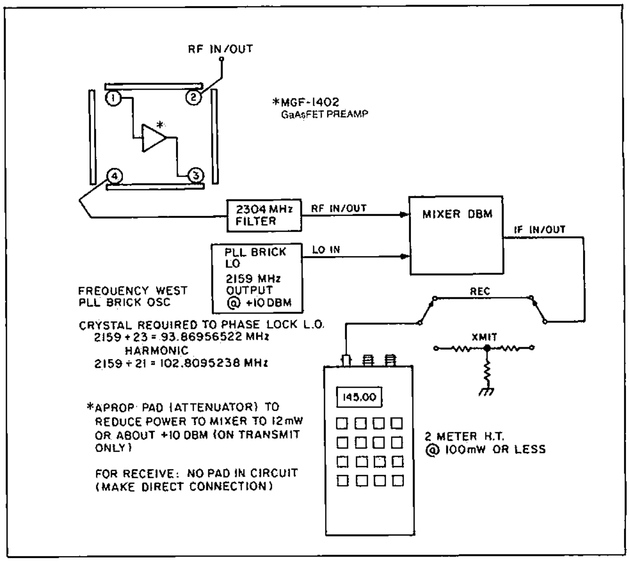

Figure 1. 2304 MHz transmit receive converter using building block method of construction.

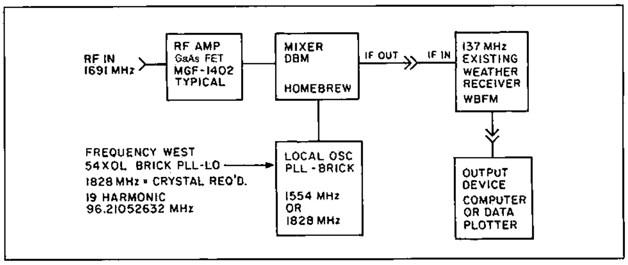

Figure 2. 1691 MHz weather receiver.

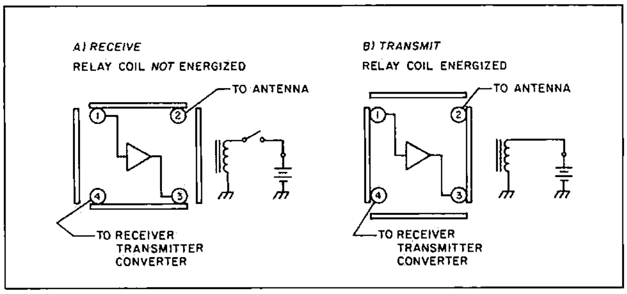

Figure 3. Coaxial transfer relay. Four-coax connector relay with the unique ability to reverse the transmission of an amplifier used non-energized for receive and energized for transmit gain.

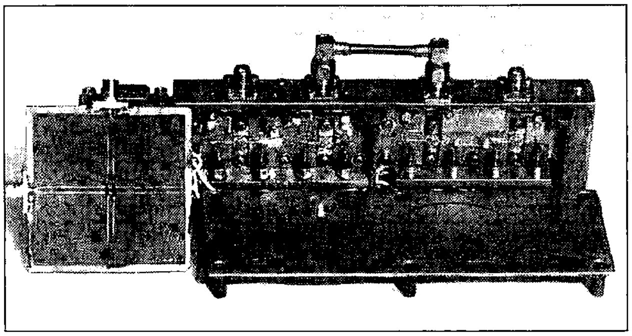

Photo A. 1691 MHz RF amplifier used in tests. This was a surplus 4-stage block amplifier with a 3 dB noise figure and 40 dB gain over 1.26–1.96 GHz. The square PC board is the home-brew mixer used for 1–2.5 GHz operation. Reference Figure 2.

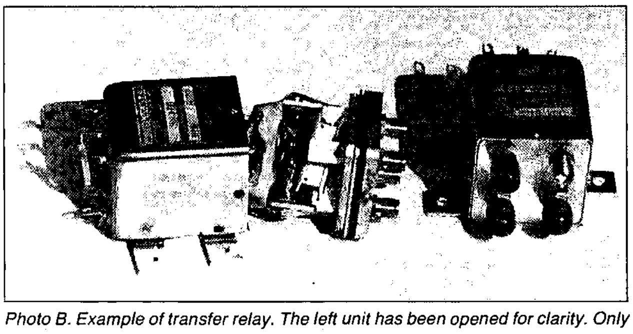

Photo B. Example of transfer relay. The left unit has been opened for clarity. Only one rocker (actuator for relay shown) transfer relay uses two rocker arms on either side of the relay coil to affect 4-port switching used for "transfer operation." See Figure 3 for details.

into the transmit path to reduce drive to a level suitable for the mixer. The maximum power needed to drive the mixer is typically +10 dBm, or about 12 milliwatts of RF. When switching is complete, the transmitter can be activated. This will produce output on 2304 MHz, FM or SSB operation.

Converters, transverters—they are all the same, no matter what frequency they are for. Usually a high frequency is heterodyned to a lower frequency for processing. The addition of filters and other switching simplify the total operation towards a one-switch operation. Timing or sequencer circuits are added to ensure proper relay operation.

Relay switching can be done manually if you choose. My station operates in the manual mode and works well. It might not be full of frills, but what's important is that it works. It just depends on how far you want to go with your project, and what you want to spend on it.

Crystal Multiplier Construction

Now comes the local oscillator. In most designs this is a crystal multiplier that needs to be constructed due to a lack of commercial equipment for 1691 and 2304 MHz. Now, I am not a lazy person, but when an easy way is available, I make use of it. This initially caused some head scratching until it became apparent that the old 10 GHz bricks are usable with minor modifications.

Last month you learned how to convert the output filter of this same brick. In this application, the filter and SRD diode multiplier are removed. Now the fundamental high power local oscillator is the LO output. I don't know why I didn't think of this before.

The operation is quite simple. The 10 GHz bricks have a high power oscillator that normally runs in the 1700 to 2000 MHz range. The 6 GHz brick's cavity oscillator runs from 1200 to 1400 MHz, making various applications possible. Take a basic 10 GHz brick (LO 1.7–2 GHz) and remove the microwave varactor multiplier and filter. This gives you direct access to the high power LO. This unit is directly under the blue label for Frequency West bricks.

Next, change the length of the cavity screw for the frequency desired. With the cavity screw seated deeper in the cavity, the frequency will be higher. Place a coaxial probe mounted on a small adapter plate over the LO high power output port. This hole was previously occupied by the varactor multiplier's RF probe. By changing the cavity length, it is then possible to make the oscillator phase-lock to frequencies as high as 2.4 GHz, making 2.159 GHz very easy to reach. This allows a 2 meter IF at 145 MHz to mix with the LO at 2159 MHz, producing 2304 MHz (or 2.304 GHz). This is the high side mix product.

For the weather satellite receiver using a system IF at 137 MHz, the LO required would be 1554 MHz (low side injection) and 1828 MHz for high side injection. I have not tried the low frequency operation at 1554 MHz, but suspect it might be possible. I am not familiar with the FM format for the weather data, but I believe high or LO side mix can work well. I am an RF person, and have never tried to receive weather data, but I will get the design worked out OK.

The crystal required for use in the brick is a high accuracy oven-controlled overtone crystal. I obtained my crystal from International Crystal Co. in Oklahoma, part number #585132 for the Frequency West brick oscillator type 54XOL. The crystals costs about $20 each. Crystal frequency can vary from 95 to 108 MHz at the frequency of oscillation. The crystals 17th to 19th harmonics are used to lock the cavity oscillator to the desired output frequency. Higher harmonics are available such as the 21st or 23rd making phase lock at 2159 MHz with a 102.8095238 MHz crystal. Using a lower harmonic would make the crystal frequency quite high and put it out of the 90 to 108 MHz range specified.

As I stated earlier, I have picked up a quantity of the 10 GHz phase-locked brick oscillators with and without the multipliers. The full 10 GHz brick with multiplier and retuned for the amateur band is $65. The basic brick without filter for the weather satellite or 2304 MHz service is $50. All prices are postpaid for U.S. destinations.

For further information on these brick oscillators, check out the many different applications covered in previous *73* articles. For temperature control and typical internal crystal oscillators, see the June and July 1990 columns. For details, including diagrams, on the 6 GHz brick, see the September 1990 column. The 10 GHz brick system was covered in the December 1989 column.

Mail Box Comments

Blair VE6AHG saw the column covering the FET Switcher (power supply) in the August 1990 issue. He has an old WWII Navy transmitter (TBW-5) he is restoring, and ran into a snag. The input power transformer is rated at 800 Hz AC input, and the switcher used to convert 12 volts DC to 110 AC is at the frequency of choice. The FET Switcher should work well. With several FETs in parallel, Blair should be able to increase current demands. The FETs are hooked up element-to-element without current equalization resistors. Use a heat sink and place transient protection from drain to ground. This transient network is a 0.1 µF capacitor and 5 ohm resistor tied in series to ground from each drain.

Jim WA9PYH saw his response for information on stripline filters in this column, and wants to say thanks for the 1296 LO PC board designed by Paul Schuch. He was going to make a copy of the artwork to try the 1296 MHz filter circuitry on the board. Jim was going to convert the filters to 1691 MHz for use with a weather satellite converter. I kind of upset his plans, as I sent a fully etched PC board with my reply. It was the same one he was going to make. Jim wrote back, "Thanks a lot! See how nice hams are. They are interested in technology and want to learn." Thanks, Jim, for the kind words.

Supplying the PC board is not only a way to answer your question, but to give your project a boost. Glad I could help out. I make my own PC boards, using the silk screen method. Once the screen is complete for a particular project, a PC board can be zipped off in no time. I have to give thanks to Paul Schuch for designing the PC board. His article for the 1296 MHz LO appeared in the December 1979 issue of *Ham Radio*.

I'll be glad to answer questions relating to the VHF/UHF microwave areas of interest. Please include an SASE. 73 Chuck WB6IGP

SPECIAL EVENTS

Number 26 on your Feedback card

Ham Doings Around the World

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the January issue, we should receive it by October 31. Provide a clear, concise summary of the essential details about your Special Event. Check /HAMFESTS on our BBS (603-525-4438) for listings that were too late to get into publication.

DEC 1

PASADENA, CA The Toys for Tots Ham Radio Rally will be held at the world famous Rose Bowl from 11 AM–4 PM, to raise toys for underprivileged children in the Los Angeles area. All you have to do is bring a new toy valued at $5 or more to parking Lot 1, just south of the Rose Bowl. All toys will be collected by the US Marine Corp Reserves. Other scheduled events are the Ham Radio Installation Concours; ham mobile rig judging for neatness of installation, inventiveness, largest number of rigs and antennas. Judging begins at 3 PM. Talk-in on 145.180–. For info call ***Bruce N6TFS, (213) 257-5502, Packet: N6TFS @ N6YN.***

HAZEL PARK, MI The Hazel Park ARC will hold its 26th annual Swap and Shop at the Hazel Park High School from 8 AM–2 PM. Admission $3 advance or at the door. Tables $12 (reservations must be received with check, no reservations by phone!). Free parking. Talk-in on 146.64– (DART). Send table and ticket reservations to ***HPARC, PO Box 368, Hazel Park MI 48030.***

DEC 7

OOTHAN, AL The Wiregrass ARC will hold a Hamfest from 8 AM-3 PM at the Wiregrass Memorial Park. Set-up from 7–8 AM. Free admission. Tables with power $7.50; without power $5. Tailgating $2.50. Concessions available on site. ATNM and Packet Forums. VEC FCC Exams on site. Talk-in on 147.340/.940. Contact ***N4RNU, 1811 West Main St., Dothan AL 36301*** for info and reservations.

FARIBAULT, MN The annual Courage Center Handi-Ham Winter Hamfest will be held at the Eagles Club in Faribault, starting with registration at 8:30 AM. There will be a handi-ham equipment auction, VE exams, dinner at noon, and program. Talk-in on 146.19/.79 Contact ***Don Franz W0FIT, 1114 Frank Ave., Albert Lea MN 56007.***

DEC 8

LARGO, MD The Goddard ARC and the Tri-County ARC will co-sponsor Holidayfest '91 to benefit Prince George's County RACES/ARES, from 8 AM–4 PM, at the Prince George's Community College Student Union Bldg. (Exit 15A or 17A Capital Beltway). There will be symposiums on Emergency Management, Antennas, AMSAT, Packet Radio, and SKYWARN. Meteorologist Doug Hill will present a Weather symposium. Free VEC Exams will be administered by the LARC VECs throughout the day. A special CW Speed Challenge contest will also be featured. Donation $4. Unlicensed spouses and children under 12 admitted free. Tailgating (weather permitting) $5. Tables are $18 till Nov. 23rd, $22 at the door (if available). Each table includes one paid donation. Plenty of free hard surface parking. Talk-in on 147.180+, 145.73 simplex, 146.835–, 444.65+. For reservations, send payment and SASE to ***Tri-Co/Goddard Holidayfest, 360 Domer Ave., Mall-Drop 120, Laurel MD 20707. (301) 572-2326.***

DEC 14

NORFOLK, VA PC Fest Computer Shows will sponsor an event at the Norfolk Scope Convention Center from 10 AM–4 PM. Admission is $6 for adults, children under 10 admitted free. For info contact ***Shows, Inc., (407) 241-1660.***

DEC 28

GAITHERSBURG, MD PC Fest Computer Shows will host an event at the Montgomery County Fairgrounds from 10 AM–4 PM. Admission $6, children under 10 admitted free. Contact ***Shows, Inc., PO Box 832049, Delray Beach FL 33483. (407) 241-1660.***

DEC 29

SOUTH BEND, IN The Repeater Valley Hamfest Committee will hold a Hamfest Swap & Shop at Century Center, Downtown on US 33 ONEWAY North between the Society Bank Bldg. and the river in South Bend. Four lane highways to the door from all directions. Tables $5/5' round; $15/8 x 2.5' rectangular; $20/8'. Wall locations. Talk-in on 52/52, 99/39, 69/09, 34/94, 145.29. Contact ***Wayne Werts K9IXU, 1889 Riverside Dr., South Bend IN 46616,*** or phone ***(219) 233-5307.***

SPECIAL EVENT STATIONS

DEC

SYDNEY, NOVA SCOTIA The Marconi Amateur Wireless Society of Sydney, Nova Scotia, will operate Station VA1S during the month of December, 1991, to commemorate the 89th Anniversary of Marconi's first successful West to East trans-Atlantic radio transmission on Dec. 15, 1902, from Glace Bay, Nova Scotia to Poldhu, Cornwall, England. An attractive certificate suitable for framing is available to confirm contact with VA1S. Send $3 or 5 IRCs to ***Alan Leith VE1AL, 846 George St., Sydney, Nova Scotia, Canada B1P 1L9.***

DEC 1

ROSE BOWL, PASADENA, CA The Toys for Tots Ham Radio Rally will operate KA6RJF from 1900Z–2400Z on Dec. 1 to commemorate the first annual Toys for Tots Ham Radio Rally charity event. Operation will be SSB in the General 40 m and 20 m and the Novice 10 m subbands. For a certificate, send a QSL and a 9 x 12 SASE to ***KA6RJF, 1302 Mar Vista, Pasadena CA 91104.***

DEC 7–8

PEARL HARBOR, HI Region Eight, Navy-Marine Corps MARS will operate KH6SP, NNN0 and NNN0ARZ, 0400Z Dec. 7–0400Z Dec 8, from Ford Island adjacent to the Arizona Memorial, to commemorate the 50th Anniversary of the Pearl Harbor attack and the sinking of the USS Arizona. Amateur operation will be in the lower portion of the General phone bands, AMTOR and RTTY in subbands. MARS operations will be announced separately. For QSL, send your QSL card and an SASE to ***KB4JI/KH6, 106 Ford Island, Honolulu HI 96818.***

HONOLULU, HI A group of Hawaiian hams will operate a Special Event Station to commemorate the 50th Anniversary of the attack on Pearl Harbor. Operation will be 1700Z Dec. 7–1700Z Dec. 8. Frequencies: Activities are planned for all bands, all modes, including Novice subbands. Look for us at the lower portion of each subband. For a QSL certificate, please send your QSL card, 6 IRCs or equivalent, and a 9 x 12 SASE to ***Pearl Harbor Special Event, PO Box 788, Wahiawa HI 96786.***

DEC 28–JAN 1

PASADENA, CA The Relay Repeater ARC will operate AA6YL from the Wrigley Mansion in Pasadena, to commemorate the 103rd Anniversary of the Tournament Of Roses; 103 years of the Rose Parade, and 78 years of the Rose Bowl Game. The station will operate from 1600Z–0400Z each day on the following frequencies: 14.260, 21.335 and 28.450. Amateurs in California/Nevada can contact the station on 2 meters via the Club repeater 144.970/147.410, on 147.21+, or on 220 meters via the Condor Connection. For certificate, send QSL and 9 x 12 SASE (58 cents) to ***Relay Repeater Club, PO Box 81, Arcadia CA 91066.***

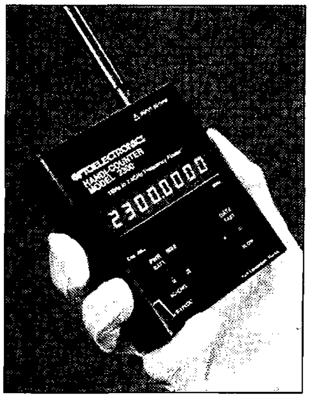
NEW PRODUCTS

Compiled by Hope Currier

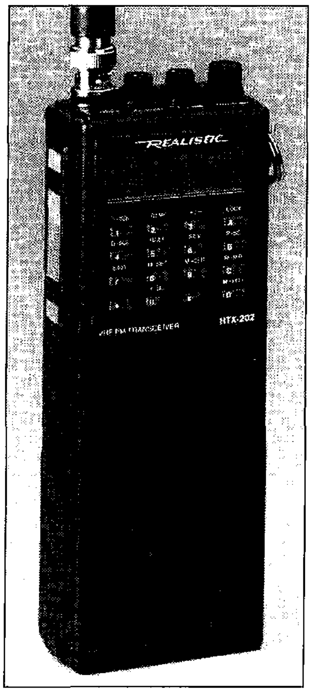


OPTOELECTRONICS

Optoelectronics Inc. has announced a new frequency detector/counter, the Handi-Counter Model 2300, for use in secure installations, countersurveillance and police tactical situations, private investigations, two-way radio, ham radio, frequency monitoring and other applications where a dedicated frequency counter is usually too costly. The Model 2300 features full eight-place readout resolution, 10 mV sensitivity for signal detection at maximum distance from the transmitter, and a unique and convenient display-hold switch so the user won't have to remember or write down the detected frequency.

The Model 2300 is priced at $99. There is an optional NiCd battery pack available for $29. For more information, contact *Optoelectronics Inc., 5821 NE 14th Avenue, Fort Lauderdale FL 33334; (305) 771-2050, (800) 327-5912, FAX: (305) 771-2052.* Or circle Reader Service No. 201.

RADIO SHACK



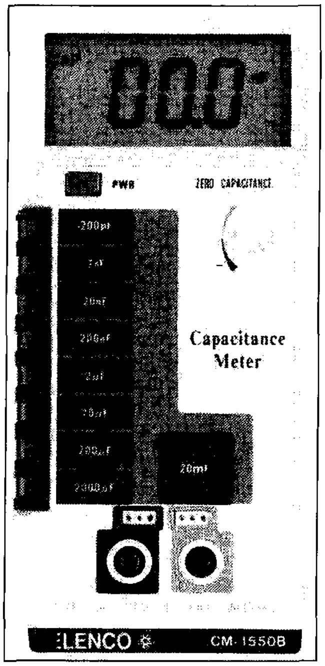
The Realistic® HTX-202 2m synthesized VHF-FM HT comes with a large-capacity NiCd battery pack/charger, a multifunction scanning system, 12 independently programmable memory channels (plus one calling and three priority memory channels), a built-in subaudible tone encoder and tone squelch, a touch-tone (DTMF) memory dialer and DTMF squelch. The highly selective receiver fights intermod and front-end overload. True FM transmit gives superior clarity on voice and outstanding performance on packet. An alkaline battery case, belt clip, charger and rubber ducky antenna are included.

The suggested retail price for the HTX-202 is $260. For the address of a local dealer, contact *Radio Shack, 700 One Tandy Center, Fort Worth TX 76102; (817) 390-3300.* Or circle Reader Service No. 202.

MILESTONE TECHNOLOGIES

CODEMASTER Version 4.0 is a new version of Milestone Technologies' Morse code training program. This upgrade incorporates changes requested by customers, especially in the area of the user interface, taking advantage of the latest compiler and processor technology. It significantly enhances user control of the program, offering a new routine for changing and saving program settings, improved performance, and a higher level of error checking.

The price hasn't gone up—the new version is still $19.95. Contact *Milestone Technologies, 3551 S. Monaco Parkway, Suite 223, Denver CO 80237-1228; (303) 752-3382.* Or circle Reader Service No. 205.



ELENCO ELECTRONICS

Elenco Electronics has introduced a new series of digital hand-held multimeters that have an extra-large, easy-to-read, three-quarter LCD display, perfect for engineers, technicians or hobbyists. The CM-1500B multimeter and CM-1550B capacitance meter have a one-half percent accuracy rate. The CM-1500B measures AC/DC volts; AC/DC current to 20 amps; and resistance, transistors, diodes, capacitors to 20 µF as well as conductance. The CM-1550B measures capacitance from 0.1 pF to 20,000 µF. Both meters have side push-button switches, and the CM-1550B has a zero control.

Both meters include Elenco's two-year warranty, test leads, operator manual, and a carrying case at no additional charge. Prices are $75 for the CM-1500B, and $79.95 for the CM-1550B. For more information, contact *Elenco Electronics, Inc., 150 West Carpenter Ave., Wheeling IL 60090; (708) 541-3800, FAX: (708) 520-0085.* Or circle Reader Service No. 203.

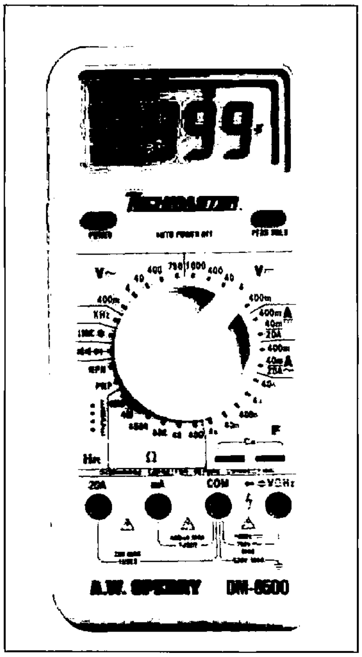
FB ENTERPRISES

FBenterprises is offering a set of handy reference cards for hams. "Quick-N-Easy 2m Repeater Maps" are maps of your state, including an up-to-date list of 2m repeaters. The back of the card lists 220, 440, and 900 MHz, and 1.2 GHz repeaters in the state. These cards are easy-to-read, and great for travel. The "Quick-N-Easy DXCC" card (see photo) has a listing of all DXCC countries, along with their most common prefix, and the beam heading from your location. "Quick-N-Easy QSO Helper!" lists the RST system, Q signals, UTC time conversion, Fahrenheit-to-Celsius temperature conversion, and feet-to-meters conversion. "Quick-N-Easy Shortwave Listening" is a series of four cards for shortwave listeners. Each card shows six hours of the day with listings for shortwave broadcast stations. The "QSL Kit" is a package containing everything needed for QSLing DX stations via the bureau, including envelopes, addresses for each bureau, and instructions on how to use the bureau.

The cards retail for $4.95 each; the QSL kit is $1.99. Dealer inquiries are welcome. Contact *FBenterprises, 8818 Rainier Dr., Vancouver WA 98664; (206) 695-3637.* Or circle Reader Service No. 204.



A.W. SPERRY INSTRUMENTS

A.W. Sperry Instruments has announced a new Techmaster digital multimeter, Model DM-8500. This rugged 3-3/4 digit, drop-proof, heavy duty, autoranging DMM can read 12 functions on 37 ranges. Its many features include a fused 20A AC/DC range, overload protection on all ranges, HFE transistor test, logic indicator, peak hold, diode test, safety yellow housing and "auto-off," making the DM-8500 one of the most state-of-the-art digital multimeters available today. It comes complete with one set of test leads (TL-58), one B-4 battery, one F-20 fuse, operating instructions and a warranty card.

The Model DM-8500 is priced at $139.95. For more information, contact *A. W. Sperry Instruments Inc., 245 Marcus Boulevard, Hauppauge NY 11788; (516) 231-7050.* Or circle Reader Service No. 207.

MARCOMP

"Mr. Morse" from MARCOMP, a customized version of a package used by the Canadian Navy, is a user friendly program which uses hypertext technology, pull-down menus, windows, dialogue boxes and selection buttons. The program is divided into two modes of operation: Learning Mode for beginners, where the characters and their symbols can be displayed while transmitting; and Training Mode for continuous training for advanced users. The Receiving Module is $39.95, the Transmitting Module (added) is $24.95, both modules together are $59.95, and a kit for interfacing an actual Morse key to the user's computer is $129.95. All prices are Canadian dollars; taxes and shipping not included. Contact *MARCOMP, #402-130 Keith Road West, North Vancouver, B.C., Canada V7M 1L5; (604) 980-5718, FAX: (604) 988-6455.* Or circle Reader Service No. 206.

THE RADIO WORKS

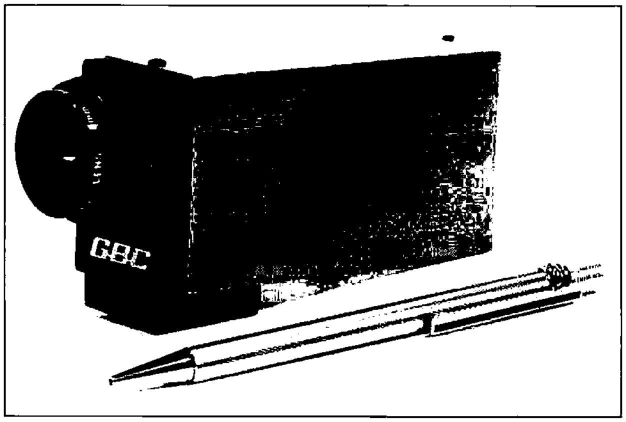
Catalog #912 from The Radio Works, an 80-page source book of wire antenna systems, parts and accessories, is now available free to *73* readers (for extra-fast delivery, send $2 for first-class postage). It includes a complete selection of coax, connectors, and antenna wire—everything for the wire antenna wire enthusiast. A full array of complete antenna systems like the Carolina Windom, "G5RV Ultra" and SuperLoop are featured. New in this issue is a line of isolators made specifically for vertical antennas, plus the 80–10m Carolina beam and the 40–10m Carolina Beam/2. Everything you need to accessorize or update your present antenna system is in this catalog, all at discount prices.

To order your copy, contact *The Radio Works, Box 6159, Portsmouth VA 23703; (804) 484-0140, FAX: (804) 483-1873.* (Mention *73*.) Or circle Reader Service No. 211.

POLYPHASER

A video tutorial, "Grounding—An Overview," is now available from Polyphaser and its distributors for $49.95. The video, approximately 60 minutes long, provides extensive information on the latest grounding techniques for communication site protection from lightning. Future videos will cover more site-selective installations, such as high-rise buildings and mountain top locations.

For more information, contact *PolyPhaser Corporation, Customer Service Department, P.O. Box 9000, Minden NV 89423-9000; (702) 782-2511, (800) 325-7170, FAX: (702) 782-4476.* Or circle Reader Service No. 208.



CCTV CORP

CCTV Corporation has introduced the "GBC" CCD-300 micro-miniature solid-state CCD camera, a vidicon camera replacement, ideal for all CCTV needs. The camera uses a unique micro-electronic shutter that allows the sensor itself to compensate for all light changes, therefore eliminating the need for an auto-iris lens. The CCD-300 can use both "C" and "CS" type lenses. It operates from low voltage (7-12V DC) and comes standard with a 120V AC to low voltage DC power module. Full video can be achieved with light levels as low as 2 lux. The camera offers resolution in excess of 350 lines, plus standard features such as adjustable gamma, auto black level, a built-in image enhancer, mirror image reversal and switchable auto/manual gain.

The CCD-300 is priced at $229.50 for *73* readers. Contact *CCTV Corp., 315 Hudson Street, New York NY 10013; (212) 989-4433, (800) 221-2240, FAX: (212) 463-9758.* Or circle Reader Service No. 210.

OWENS/BROWNING SOFTWARE

CW Simulator software from Owens/Browning Software includes Morse code training features that ham radio operators have requested: adjustable code speed and tone; beginning lesson menu; display in groups, lines and characters; "Hide and Seek" text option; letters, numbers, punctuation and Q signals; random character and callsign generator; and standard and Farnsworth modes. It has a QSO generator capable of over 700 billion combinations (users can edit and create new text); a screen editor to create, save and play back user-created QSOs and messages; a plaintext generator for three-, four- and five-letter words; and the ability to calibrate software code speed to the PC clock. The program offers on-the-air simulation, teaching the operator to copy through QRM and poor operator rhythm.

CW Simulator is available on 3.5" and 5.25" diskettes, for $24.95 each. Contact *Owens/Browning Software, 954 Church St., Hutchinson MN 55350.* Or circle Reader Service No. 209.

COYNE CO.

MacHam™ software programs from the Coyne Co. are test generator/study aids for getting a no-code Technician class ham license, and for upgrading. "MacHam Technician" contains all 700 possible FCC questions for the code-free Technician test, covering both elements 2-Novice and 3A-Technician. The MacHam programs for upgrades cover all possible questions from elements 3B-General, 4A-Advanced and 4B-Extra, respectively. Each program will generate FCC-style exams and any number of unique tests are possible. Exams can be taken on-screen or in printed form. An on-line glossary of key terms is included. Hardware requirements: any Macintosh computer, Mac Plus or newer; 2MB RAM and a hard drive; and a Macintosh-compatible printer.

The suggested retail price for MacHam Technician is $49.95; MacHam General, Advanced and Extra are $34.95 each. Prices include shipping. Contact *Coyne Co., P.O. Box 2000-200, Mission Viejo CA 92692; (714) 855-4689.* Or circle Reader Service No. 212.

More Gain

Before we continue our discussion of gain, I'd like to sidetrack a little and discuss a topic which may surprise you. In the three years I've been writing this column, we've covered just about every component used in modern radio gear, right? Well, there's one we've overlooked, and I was reminded of its importance by a problem I had with my TS-940.

I've had the rig for about five years, and never noticed anything wrong. Recently, though, I was fooling around with it while it was connected to my dummy load, and I discovered that the "high cut" control, which narrows the high side of the receive passband, was affecting my transmit audio as well!

The '940 has an IF monitor function which lets you listen to your actual transmit signal. Sure enough, my voice was being severely muffled in transmit whenever the high cut control was turned toward the narrow side. Even weirder, the problem only occurred when I was in LSB; in USB, the rig behaved perfectly normally! What was going on here?

Up with the Scope

Naturally, I dug out my oscilloscope and started probing. Luckily, I have the service manual for the radio, so I knew where to look. Actually, I needn't have bothered with the scope. In fact, I could have left the rig's covers on; a little deduction was all that was really required. Let's look at the facts here: Everything works fine in receive, where the control is supposed to function. It is properly locked out in transmit as long as the radio is set to USB. A look at the service manual reveals that the high cut control functions by the microprocessor's reading the position of the knob and sending data to the PLL, which then shifts an oscillator in order to shift the signal around within the SSB filter's passband. If all this stuff works, then how could it be broken only in LSB? The answer is: It isn't! The rig is shifting the PLL when it shouldn't because *the software is telling it to!*

Does Software Break?

You got it, it was defective software. Today's radios, which are virtually all microprocessor-driven, depend upon their system software to control most functions. A defect or bug in that software can make the radio seem broken, and in effect, it is. Yes, software is a component after all! Don't overlook it as a suspect, especially in obscure cases like this one, where nearly everything works and the pieces of the puzzle just don't add up.

Thanks, Guys

Kenwood was unaware of any bugs in the TS-940 operating system, but they suggested that the EPROM (which holds the software) in my rig could be defective. Although EPROMs don't fail that way (in the rare event of failure, they go completely), it occurred to me that mine could have glitched a few bytes during its factory programming. In any event, a new EPROM from the nice folks at Kenwood fixed the whole thing up. Case closed!

Gaining on Us

Let's continue our discussion of gain. We've seen what it is and why we do it. So what's the big deal, right? We know how to make amplifiers by the barrelful. But not so fast. If you've ever built an amplifier stage, you know that its gain drops off with increasing signal frequency. Audio amps are completely useless at RF. Why should that be?

The answer is: capacitance. Any time you have a voltage potential across any two circuit elements which are near each other, those two elements will exhibit capacitance along with their other properties (such as inductance, resistance, etc.). Unfortunately, this essential fact of life extends even to electrodes in a tube or layers in a semiconductor.

Thus, transistors, diodes, or any parts for that matter, have capacitance between their leads. In other words, they store charges. The result is that they have speed limits beyond which those internal capacitors cannot charge and discharge fast enough. The result is that there are numerous little low-pass filters all over the circuit. Every circuit has them. And, if you recall, the impedance of a given capacitance value goes down as the frequency goes up.

So, as the intended signals rise into the RF range, those tiny capacitances, which have little or no effect on audio signals, start to short out the RF signals you want. The result: The gain drops off until there is none left. In fact, you wind up with *less* signal at the output than you fed in! This is called negative gain, but really, it is *loss*.

Two Ways Out

There are two ways out of this situation, and each has its place. The first is obvious: Reduce the stray capacitances until they are low enough that they don't cause trouble. It works—to a point. Especially with small signal amplifiers, gain devices (transistors, ICs and tubes) are available that have been designed to have very low capacitance. They make nice RF amps up to and beyond 30 MHz.

The other solution is to make the existing capacitances part of a tuned circuit which resonates at or near the frequencies you want to amplify! Now, that same pesky property is turned to your advantage because, as you surely know, nothing works as well as a tuned circuit! This is precisely the technique used in the final amps of rigs with tube finals, and a few early transistor finals were made that way, too. Now you know where the TUNE and LOAD controls came from—they set the resonant circuit to the frequency you are trying to amplify.

It is possible to make no-tune RF amps. Most solid-state rigs have them, and some tube linear amps use them also. Basically, they are broadband tuned circuits. I know that sounds like an oxymoron, but it can be done. You just use a very low-Q LC (inductive-capacitive) combination with no distinct resonant peaks within the desired passband. As long as you cancel the circuit's internal capacitance with sufficient inductance, it works. In practice, it's a bit harder to do well than it sounds.

More Than Amps

Last month, at the beginning of this exploration, I stated that gain was the foundation for virtually all electronics. We've examined amplifiers, but it takes more than amplifiers to make radios, computers, TVs, etc. Let's look at how gain can be turned to other uses.

You know how placing a microphone too close to a PA speaker causes feedback howl? Well, that's exactly how oscillators work. They're just amplifiers which "hear" their own signals, causing the signal to go around and around. The speed of travel is limited by circuit capacitance, and by deliberate means such as coil-cap, resistor-cap, or crystal resonant circuit elements. If a voltage-tunable capacitor (called a varicap or varactor diode) is used, you've got a VCO (Voltage Controlled Oscillator), which is an important part of most frequency synthesizer schemes.

In order for the oscillator to work, the direction or "phase," of the output must be the same as the input. That's called noninverting gain. When the phase is opposite—when the output goes down as the input goes up, and vice versa—you have inverting gain. An inverted signal cannot reinforce itself at the input, so there can be no perpetuation of the signal. It's a useful technique when you want to *avoid* oscillation in a circuit meant only to amplify.

Open the Gate

Digital gates, from which all computers are built, are amplifiers, too! The foundation of the binary digital technique is that there are only two circuit states: on and off. So, these amplifiers are deliberately designed to have extremely poor linearity! They are always either driven all the way on, or they are off. Actually, the internal construction of a typical digital gate looks remarkably like that of an audio amplifier. Inverting amplifiers are used for inverting functions like inverters, NAND and NOR gates. Noninverting amps are used for AND and OR gates, as well as buffers. By the way, an entire computer can be built from NAND or NOR gates. But it would take an awful lot of them to build a PC clone!

Now, let's look at some letters:

Dear Kaboom,

I have an ICOM 575H 6 and 10 meter radio, and I need an antenna tuner for it. Daiwa makes one, but they only sell it in Europe. Any ideas?

Signed, Out of Tune

Dear Out,

An antenna tuner is a very simple thing. Really, it is just a coil and few variable capacitors. The first thing I'd try is to borrow a small tuner from a friend and try it, even if it isn't made to cover 6 meters. Start with the inductor set for minimum inductance and give it a try, keeping the rig set for low power while tuning the capacitors. The tuner's SWR meter will probably be a bit inaccurate at the higher frequencies, but it should still suffice for relative indications, which is all you need anyway. I'd stay away from big, kilowatt tuners here, because their larger components are likely to have too much stray reactance to work well at 50 MHz. If you can't get it to work, why not build your own tuner? Check the ARRL *Handbook* and other antenna project books for plans. Lots of hams build their own tuners, and you can, too!

Dear Kaboom,

Sometime back you mentioned the KDK FM-2016A 2 meter mobile. I have one with a problem. The transmit frequency is off by 3 kHz on the high side. I've tried adjusting the oscillator trimmer and also the three offset caps, but no luck. What can I do?

Signed, Off and Tired of It

Dear Off,

Yeah, mine's had that problem, too. You need a new crystal, which you can get for a few bucks from any of the crystal houses advertising in the backs of the magazines. If the frequency is off only in the + shift position, replace X2, which is the 13.966 MHz crystal. After you replace it, be sure to set the trimcap for the correct frequency and also to readjust the trimpot next to it by setting the +5 kHz switch on and turning the pot for the correct frequency.

73, and see you all next month. 73

Never Say Die

Continued from page 4

often exciting. And beating down the pile-ups, hour after hour, is a rush you'll never forget the rest of your life. What does it take to blast you away from the boob tube and your nightly net? Or are you investing the few hours left of your life numbly watching quiz shows, sitcoms and soaps, drinking beer and eating potato chips? Oh, I see those flabby beer bellies hanging out from under your dirty tee shirts and over your belts at hamfests.

Albania was one of the last bastions. One of the rarest of the rare. I forget now how long ago it was that Frank DL7FT/ZA got on the air for a few hours. . . yes, of course I worked him. I think he got permission from a minor official and it took a while for higher officials to overrule the decision and escort Frank back over the border.

But you don't have to go for the #1 needed country. If you just go down to the Caribbean you can find some fairly rare islands which'll guarantee you pile-ups. Visiting these are more a matter of your doing some research and having the initiative. No dangers involved. No pioneering. But one heck of a lot of fun. And if you take some pictures you might get published in *73* by a jealous editor. A very jealous editor.

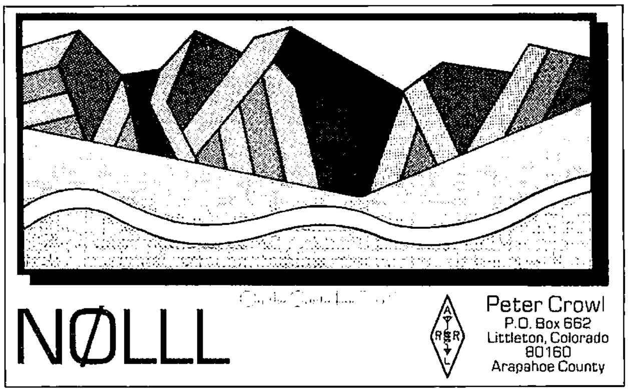
It's been a couple years since I got on from W2NSD/FP8, so I need a DXpedition fix. I'm definitely antsy. I've got my pictures out from my 7P8 and 3D6 trip. . . sigh. Then I've been invited on a diving trip for next March to New Caledonia. I haven't operated from there in years. I haven't even kept in touch with all my ham friends in Noumea.

What'll it take to get you off dead center and into action? Don't you get excited thinking about it? I suppose I should tell you about when I got on from Nairobi, Beirut, Damascus, the American embassy in Tehran, Kabul, Katmandu, and so on to get your fires warmed up.

I guarantee I'm busier than you, but that doesn't mean I wouldn't drop everything in a minute and head to Albania. The readers who responded to my September editorial asking for help setting up a national rep organization to sell music and music publications will get an idea of the number of projects I've got going. It's such a network of interrelated projects that I think there are only one or two people working for me who understand how it all fits together.

I do my letterhead on my laptop computer because the number of my companies changes every few days. Of course I suppose I come across as a Great Panjandrum as a result. Put it down to the Wizard of Oz syndrome. But yes, I'm busy. Of course, since I retired in 1983 I've been just having fun and I rarely spend much more than half a day "working". . . 12 to 16 hours, tops. Okay, so where shall we go and raise some hell on the bands?

Let's not forget to take along SSTV. I had it with me at KC4DX, JY9AA and 7P8PA. We'll need packet and OSCAR gear. RTTY? Why not? I had a great time on RTTY from Bangkok not long ago. Are you packed yet? Burma seems to be opening up. When I visited there was no hamming. Ditto when I visited Baghdad, but I'll bet King Hussein could put in a bad word for me and YI2NSD might be able to hit the ground running. Or should I start another magazine instead? I've got this *Secret Guide to FREE Music* I want to get going. . .



QSL of the Month To enter your QSL, mail it in an envelope to *73*, WGE Center, Forest Road, Hancock, NH 03449. Attn: QSL of the Month. Winners receive a one-year subscription (or extension) to *73*. Entries not in envelopes cannot be accepted.

The Magic of Communications

Until you are robbed of both the visual and audio cues we're used to getting while talking, you don't realize how important these things are for communications. This, more than anything else, is what causes mike fright. Suddenly we have to talk to someone and we're not getting the cues we've been used to getting all our life. No nods, no eyes to see, not even any uh-huhs to keep us going.

It's no wonder so many of us tend to get into habit patterns, saying essentially the same thing for one contact after another. . . day after day, year after year. What can we talk about? We call a CQ, get a call from someone who gives us nothing more than a callsign. So we have to start off with the basics. . . name, location and signal report. Then we feel we should say something else. . . like what? We don't even know his name yet. So how can we get any kind of a conversation going? The weather? Good grief! How about your rig and antenna? You know he doesn't care any more about that than you do, so why waste your breath?

It's embarrassing to start reading off a list of your interests, so that's out. In a couple of years I hope we'll have a way to send such a list, perhaps via packet or a sub-carrier, so it can be displayed on the screen on the other chap's rig. Better yet, a fairly simple processor in your rig could match your interests against his and highlight them on your screen.

Meanwhile, how are we going to get a real QSO started? Maybe this is insurmountable and we should just forget even trying to use amateur radio for meaningful communications. Perhaps we should just give up and use it for contests, DXing (which is a form of contest) and checking into nets where we've already known everyone for a long time.

Duplex

It's a shame that we didn't at least build our repeater systems so they'd work full duplex. Back before the FCC changed the rules, I used to love working duplex on 160m with four to eight stations all sitting there talking, just as we would in a living room. I think it was January 1938 they made that illegal. Oh, they didn't intend to. . . that was a by-product of their wanting to stop a handful of jerks who were broadcasting records for hours at a time. Yes, we've always had a good supply of jerks.

So the FCC dumped a rule on us which said all transmissions had to be for the purposes of communications. That scotched the records all right, but it also had the FCC monitors sending out pink QSLs for duplex contacts.

We could get back to duplex on our repeaters if we'd use two-band rigs. Then two of us could transmit on two 146 MHz channels and listen on 222 or 450 MHz. Anyone want to give it a try and write about it?

It would be much more difficult to do this on the HF bands, but if you separated your antennas a bit, you could work duplex from one end of 10m to the other. . . and probably 15m too.

I used to have a ball getting some fairly rare DX stations into a 75m net via my 20m station. I'd relay the 75m net on 20m for the DX station and then relay the DX station from 20m to 75 so he could talk to the net. It worked great and was exciting.

I got an FCC monitoring complaint about it once, but they backed down when I explained that (a) all my transmissions were for the purposes of communications and (b) I'd checked with the FCC in Washington before I did it.

As long as you've got at least two stations on one band you can legally work duplex orossband. A devious person might set up a duplex operation with another station and give the call of a fictitious third station just to give the facade of propriety.

But what about QRM, I hear you grumbling? Sure, that's a problem, but not an insurmountable one. Ten meters is essentially dead for many hours a day, so you wouldn't be likely to get much interference if you you used it for ground wave contacts. Fifteen meters will be dead more and more of the time as the sun spots fade again. Then there's poor old six meters, which has almost been abandoned.

It doesn't take a lot of ingenuity to set up a remote station on, say, 20m. It only has to be far enough away so your receiver doesn't block. I used to have my 20m station linked via a 2m repeater so I could operate it from anywhere around town via a 2m HT. That worked out fine, allowing me to make DX contacts while getting my morning exercise, climbing Pack Monadnock Mountain.

So let's use some imagination and get more fun into hamming. If you can start a movement toward duplex operation, you may be able to help us break the boredom barrier. Let me know how you make out. And let me know if duplex operating doesn't bring excitement and fun to your hamming.

Bad Mouthing the League

I got a letter last month griping that "I'm always bad mouthing the League." Let's mull that one over. Bad-printing would be a more accurate term for the perception.

When I get a letter like that I know two things. I know that the writer is (a) not a thinking person and (b) has a religious affiliation with the ARRL, not a rational one. Let me explain the situation.

As the dominant publisher in the ham field, the ARRL has, to my mind, a responsibility to do its best to keep the hobby healthy and make it grow. It's the League's failure at these two basic responsibilities which I deplore. . . and which I often comment on, offering constructive criticism.

In the music field my magazine, *CD Review/Music & Audio Reviews*, is as dominant as *QST* is in amateur radio, so I feel a responsibility as the publisher to help the music industry be healthy and grow.

When I was publishing computer magazines I accepted the responsibility that came with my dominance in that field and helped the field to grow with books, the first mass-produced software, a computer show in Boston and so on. None of these were big moneymakers, but I felt they were important for the growth of the industry.

In the music field the industry has been taken over by a cartel of six international megacorporations (mostly foreign owned) that now control over 95% of all music sales in America! That doesn't seem healthy to me, so I'm working to bring about some changes . . . as I mentioned in September. The music business is big enough so even 5% of it is significant, running to around $400 million a year in sales. My goal is to build that to maybe $4 billion.

In September I asked for hams inter-

ested in making some spare change as reps for my distribution company, Creative Music Marketing. We've already got a nice stack of applications, so we're in business.

Reps will help get my magazines, plus about eight other music magazines, which we also distribute, into record, music instrument, book, and hi-fi stores. They'll help us distribute music from several hundred independent record companies. They'll help distribute our "Adventures In Music" sampler CDs. They'll help get new releases played on local radio stations and reviews in local papers. It's a fantastic business for anyone who loves music, and should eventually pay off very well.

Just as I'm helping the music industry to grow and to clean up some of the dirtier aspects of the business. . .such as the radio payola which was recently documented by the best seller *Hit Men*, and a sorry lot of crooked distributors. . .I believe the ARRL directors should be working with every tool at their disposal to help us clean up the messes we have on our bands. I also believe they should make it their business to get the growth of amateur radio back to where it was before the League stopped it dead in 1964.

Yes, the no-code license, which the ARRL fought for years, has increased our growth, but it's still far short of the steady 11% growth we had in the 1945–1964 period. The League, if the directors wanted, could turn this situation around in a year. I've outlined what needs to be done many times. . . known as "League-bashing."

There was a wonderful article in the September issue of *Success* magazine on goal setting. "Every successful person is an obsessive goal setter." The article pointed to a study made of the 1953 Yale graduating class. They were asked (a) Have you any goals? (b) Have you written them down? (c) Do you have a plan for accomplishing them? Only 3% answered yes to all three questions. Twenty years later the group was surveyed again. The 3% who'd said yes were more happily married, more successful and had better health. . .and 97% of the net worth of the class of '53 was in the hands of that 3%. It's almost enough to make a person think.

Says *Success*: "You can go through life, or you can design one. If you have a plan, if you have a goal, then opportunities pop out in front of you. Most people spend more time planning their vacation than they do their life."

It also points out that, "Doing anything for money is instant failure," and "Studies show that 58% of Americans never read a non-fiction book once they finish school. . .the average person listed in *Who's Who* reads 20 books a year. . .now tell me who has the better chance at being successful?"

I've got all kinds of opportunities to use my guerrilla marketing approach in the music business because the six majors are run by financial guys, not music guys. The music industry is much like a third world country with a few very rich people and the rest in abject poverty. Of such conditions revolutions are made. . .and I'm starting one.

My *IMPS Journal* is read by 5,000 independent music producers. My *Music Retailing* is read by about 5,000 independent record store owners. These are the only publications reaching these groups regularly, so they give me an enormous advantage in mounting my guerrilla attacks.

If the ARRL directors would set up some goals. . .and then honor them . . .our hobby would benefit endlessly. They did set up a goal a while back to promote the hobby and bring about substantial growth. Then they did almost nothing to make it happen. How much credit should they take for the current spurt in growth? I've seen letters from Newington taking full credit for the no-code license. Before any HQ arms get broken with self-congratulation, there should be some admission that we'd have had no-code at least 10 years earlier if the ARRL hadn't fought it with every trick in the book. The League reluctantly endorsed the idea once there was no further way to stop it.

League old-timers are still griping to anyone who will listen. . .and not many will. . .that the no-coders will ruin the hobby. They're nothing but dumb CBers, they claim. These old turkeys stopped reading *73* years ago. . .if they ever did. . .so they don't know (and don't want to know) that the new no-code licensees are turning out to be some of our best operators. They don't know. . .and don't want to hear about it. . .that the newcomers are, almost to a person, getting busy learning the code so they can upgrade. Closed minds ward off such data.

As my grandmother used to say, "A man convinced against his will is of the same opinion still." Max Planck, who ran into the same problem with his quantum theory, said essentially the same thing. Some old-time scientists are still fighting quantum theory.

I keep Max's quote on my office wall. "A new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die and a new generation grows up that is familiar with it." Keep that in mind as those doddering old-timers grouse about no-code at club meetings. They're old, so you'll be seeing them in Silent Keys ere long.

Of course, with the average ham age in the mid-50s these days, most of us are headed toward pulling the big switch. You can react to that news by giving up and making everyone around you as miserable as possible while you await your final blessing from the ARRL. Or you can say, hey, I've got to get moving and get some things done that need doing. . .set some goals and pursue them.

If helping to clean up amateur radio and get it growing by ousting the old guard ARRL directors doesn't appeal to you. . .and if you aren't particularly interested in helping me clean up the music industry and open it up for entrepreneurs. . .perhaps you can get your teeth into something else where you'll make a difference.

I'm active in the education field and I'm already making a small difference. The governor (NH) appointed me to the new Economic Development Commission to try and get New Hampshire back in the black. I've got some plans for helping our largest industry, tourism, grow. . .with a goal of doubling in the next three years. And I've got some educational plans which should bear fruit in about 10 years, attracting high tech entrepreneurs to the state.

If I can improve New Hampshire tourism, you can bet other states will soon follow suit. Ditto education. This is a perfect state for things like this in that it's small enough so it's easy to know the governor and other key players. . .like the richest guy in the state, who is also a good friend and supporter.

New Hampshire has always been progressive. We had the first aerial tramway in North America (1938). We had the first lottery. We've had two governors who became presidential advisors.

The current unemployment in NH has mostly to do with the high concentration of larger high tech businesses such as DEC, Data General, Wang and so on. Too much bet on fading technologies. . .too much on defense contracting. New Hampshire needs to actively attract small high tech entrepreneurial businesses if it wants to avoid future recessions.

Once the large companies falter they start laying off thousands of workers. This has a domino effect on construction, home prices, car sales and so on. It depresses everything. Entrepreneurs, on the other hand, are able to quickly adapt to changing technologies and ride each succeeding wave. It's far easier to be in front of a trend than to try and catch up later.

The microcomputer is making both the mainframe and the minicomputer obsolete. Anyone but the accountants running the big companies saw this coming years ago. Indeed, I wrote about that in my editorials 15 years ago, explaining exactly what I expected would happen. . .and it has.

What do I see ahead in the ham field? Either we accept the responsibility and force the ARRL to do what its charter says it should, or we're dead meat. We all know in our hearts that technology is rapidly making amateur radio a pathetic relic of the past. Sure, CW is fun. So is DXing. But do we really believe that we're going to be able to hold onto hundreds of billions of dollars of radio spectrum for the amusement of an aging group of old men? Old *white* men?

We either bring in youngsters by the hundreds of thousands and encourage them to experiment with new communications modes or we're goners, but just don't know it yet. Bill Hoisington was busy experimenting with new modes until he died in his 80s. He was at that since I first met him as W2BAV in 1948. Age is no excuse for vegetating.

Old-time readers will remember Bill's dozens of articles in *73* on building microwave transmitters and receivers using simple, inexpensive transistors and test equipment.

Ham Broadcast Service Coordination

Just as repeaters started sprouting throughout the VHF bands 20 years ago, we are seeing a ham broadcasting service starting to spread through our HF bands. And just as we found it critically important to set up voluntary repeater coordination to limit interference, perhaps it's time for coordination to help keep our ham broadcasting services from interfering with each other.

Some Basic Rules

Since the FCC has provided no real guidelines for this service, I'm going to propose some which seem reasonable to me. If you disagree, please let me know what you suggest as an alternative.

For instance, since it's so simple to set up a ham broadcasting service using a tape recorder that almost any ham can do it, I propose we agree up front to try to keep news broadcasts under one hour in the interests of spectrum conservation.

Of course our role model for ham broadcasting should be W1AW, which has been doing this with great success for decades. Few of us can hope to equal their incredible (and horrendously expensive) array of Harris commercial broadcasting equipment, but their computer control, which allows the station to be run with no operator present, can be easily emulated. Indeed, articles on software for this application will certainly be of interest.

In order to keep interference minimal, I suggest we plan to give broadcasters 10 kHz channels. Since K1MAN has claimed 14.275 kHz for his own on 20m, we can allocate from there on down the band, stopping at 14.225, which would give us seven channels. Once those have been allocated we might want to continue on up to 14.325, giving us five more channels. This could be a great solution to KV4FZ's continuing 14.313 garbage heap.

Once those 12 channels have all been coordinated, we'll need to consider a time-sharing system, with perhaps some transmitting on the even hours and the alternates on the odd hours.

But What About QRM?

First, the FCC regulations say clearly that it's necessary to check a frequency before transmitting on their self-assigned (commandeered) frequencies, whether anyone else happens to already be using them or not. Many nets operate on the same principle. . .that they are the primary users of the frequency and have an inherent right to them.

Once we have enough broadcasters in operation, most hams will probably be so busy listening to these interesting broadcasts that they will have little need to transmit, anyway. Thus, each ham broadcaster could easily keep hundreds or even thousands of other ham operators busy listening, thus reducing QRM significantly.

Material To Broadcast

The FCC regulations state that ham broadcasters must transmit information of particular interest to amateurs. This could include discussions of proposed rule changes. It could include technical discussions. It could include theory lectures and code practice to help amateurs upgrade their license grades. It could include DX and DXpedition information and lists of QSL handlers.

In fact, almost anything can be discussed, as long as even a remote connection is made to amateur radio. I'm looking forward to making tapes discussing in detail every one of my DXpeditions over the last 33 years. And for those of you with color slow-scan equipment, I'll have some nice color pictures of the DX stations and rare countries I've visited. I've got thousands of fabulous pictures.

There's no reason bulletins have to be all on voice, CW or SSTV, so I'm sure we'll be seeing RTTY, ASCII, and other computer-readable formats turning up.

Just as we have hundreds of ham nets, I'll bet we'll have special interest ham broadcasting. . .for ham doctors, lawyers, submarine vets, G.E. employees and ex-employees, UFOs, MAC users, PCers, and so on.

I hope we don't run into the problem we have with repeaters where we've almost reached a 1:1 ratio. . .one ham for each repeater. This at least has the benefit of keeping our VHF bands almost totally silent, other than for random automatic repeater identifications. The up side is that once we saturate our bands with ham broadcasters, we'll have less of a need for coordination, since everyone will be transmitting and almost no one listening.

Quality Counts

If you've been listening to the W1AW and K1MAN daily broadcasts, you already know many ways you can substantially improve on the services they are providing. For instance, you certainly don't want your broadcasts to be as deadly pontifical and humorless as those from W1AW. And please try to avoid those self-promotions and egregious ego-gratifications which characterize K1MAN's endless tirades.

You want your material to be interesting, amusing, and helpful to your listeners. After all, you're in the world of broadcast radio now and you win or lose your listeners not so much on the information content of your broadcasts as on their presentation. You're in show biz. Non-profit show biz, to be sure. . . much like our public radio systems such as NPR, APR and college radio stations. This means you'll build your listening audience more on your interpretation or slant on the news than on the news itself.

Data Services

With computers so ubiquitous, there's no reason not to include data transmissions at the end of voice broadcasts. I've suggested including slow-scan video so you can include illustrations. . .such as pictures of hams who have done something outstanding (good or bad) and their stations. You might show QSL cards from rare DX stations.

For greater illustrative detail, you'll want to go to desktop publishing technology and scan in things like schematics or magazine pages and send them as data. Music, too, can be sent as data, using the standard compact disc encoding format. Yes, you can legally transmit music this way!

Then there are items such as lists of hamfests, auctions, and other such club activities, contest schedules, rules and results from the hundreds of contests and awards around the world, data and comments on pending rule changes, even complete scanned-in club newsletters and foreign ham magazines. Wait'll you see some of the marvelous construction articles appearing in the Japanese magazines! The FCC's recent hints that it may no longer object to us selling ham gear over the air could open a whole new broadcasting and data arena.

Simultaneous Broadcasting

Ham broadcasters will want to emulate W1AW and K1MAN by developing their services to cover several amateur bands at once. This means buying more transmitters, but that's just more business for our ham industry. If hundreds or even thousands of ham broadcasters buy eight or 10 transmitters each, it'll do wonders to improve the ham industry economy. I don't recall any rules against transmitting on several frequencies in one band at the same time.

Paid Operators

Obviously a strong ham broadcast service will be more than can be accomplished with all volunteer operators. Ham broadcasters will have to operate seven days a week and at least around 12 hours a day. This is going to mean paid operators. Fortunately for us W1AW has set a precedent which, though it was patently illegal, has been accepted by the FCC for many years. It's legal to pay ham operators to broadcast. You can also pay them to write the material, record it and transmit it.

Unfortunately, that brings up something none of us want to talk about or admit to even obliquely. . . how to bring in the money it takes to pay a staff. Well, one way is to set up some sort of national or even international ham organizations and charge a membership fee.

Another might be to work a deal to innocently weave product mentions into your broadcasts. For instance, you might comment at length about how this or that famous DXer is awfully fond of drinking an ice cold, refreshing Coke when the going gets rough. Or that a ham luminary who will be giving a talk at the such and such ham club will be staying at the local Embassy Suites hotel, where they serve fantastically delicious breakfasts at no extra charge and have TV sets in both the living room and bedroom of their surprisingly inexpensive suites.

I'm sure our legendary ham ingenuity will find a way to circumvent what's left of our tattered regulations.

Special Interest

I suspect that many of the early ham broadcasters may, like K1MAN, be driven by emotional considerations more than by public service, so we'll probably be hearing ham broadcasters with special interests holding forth and slanting their material to support things like homosexuality, women's rights, women's choice, anti-abortion, rain forest preservation, tree hugging, baby seal protection, dolphin saving, education bashing, Christianity, Mormonism, Islam, world peace, famine relief, Libertarianism, and so on.

But, you expostulate, some of these things are pretty far afield from amateur radio. Is not to worry. . . that aspect of ham broadcasting has already been pioneered by W1AW. Far's I know, the FCC has never in all these years cited W1AW for addressing their broadcasting to non-amateurs. And what else would you call their code practice transmissions?

In my day, over 50 years ago, they were sending code practice at 13 wpm to help non-licensed listeners pass their first license tests. When the code speed was dropped to five per they lowered their practice speed. These transmissions clearly were not addressed to license amateurs. Thus we have at least a 50-year acceptance by the FCC of using our amateur bands for broadcasting to non-amateurs. I'd say that's a pretty clear-cut precedent.

Frequencies

With K1MAN tying up 3975, 14275 and 28475 six times a day (0745, 1100, 1300, 1700, 2100, and 0000 UTC) for 45 minutes at a time, newcomer broadcasters are going to have to go some to get ahead of Baxter. He even goes on AM on Sundays on 3890 and 7290 at 2300Z.

I like the idea of high fidelity AM transmissions. Yes, they sure do fill up a 10 kHz channel, but they're much easier for SWLs to tune in, possibly attracting new hams to our hobby from the listener ranks, since most inexpensive shortwave receivers aren't equipped to handle SSB.

Coordination

I will be glad to list ham broadcasting service stations, along with their frequencies and times, plus any special interests they may cover. Once listed in *73* they may then announce themselves as "Amateur Radio Official Broadcast Stations" (AROBS).

Am I Serious?

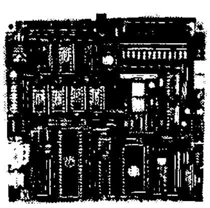
Yes, of course I am. . .this is a serious test to your credulity. . .just as the K1MAN transmissions are a test of your ability to put up with a massive waste of our frequencies and patience. 73

CAT-500 Repeater Controller

The features you have been looking for at a price you can afford.

Features Include:

- *Voice Synthesizer*
- *(2) Programmable Voice IDs*
- *(6) Programable Messages*
- *Digital Voice Clock*
- *Grandfather Clock*
- *(64) Control Functions*
- *(60) Position Scheduler*
- *(8) Macros*
- *DTMF Pad Test*
- *DTMF Repeater Access*
- *DTMF Window*
- *DTMF Audio Muting*
- *(8) Preset Link Frequencies*
- *Link Serial Tuning ***
- *Courtesy Beeps*
- *CTCSS Receiver Input*
- *Autopatch **
- *(70) Speed Dial Numbers **
- *Phone Number Lockout **
- *Reverse Autopatch **
- *DVR Control ***



** (Requires T-500 Telephone Interface Card)   ** (Requires MF-500 Serial Intreface Card)*

Configure the CAT-500 to suite your particular needs. It is as simple as setting a dip-swith. In addition to controlling your repeater, the CAT-500 auxilary input will support anyone of the following: a second repeater, control receiver, serial tuned link transceiver, autopatch or DVR. The choice is yours.

Controller Board $379.00 Wired and Tested

Computer Automation Technology, Inc.

RANDOM OUTPUT

David Cassidy N1GPH

It being December (even though I'm writing this in October), I wanted to write a quaint holiday story—maybe something about all those repeater groups who bring Santa Claus to kids in hospitals, or a tender and touching story from my childhood. I'm sorry, but I can't do that. There are a few things going on in our hobby right now that are too important to wait until January.

The Haller Hustle

FCC Private Radio Bureau Chief Ralph Haller (N4RH) announced at an FCC Forum held during the ARRL National Convention that the FCC is considering a rewrite of Rule 97.113. This is the rule that tells us what we can't transmit over amateur frequencies—business communications, messages for hire, broadcasting, music, etc. In a nutshell, what Haller proposes is to allow certain types of business communications on the ham bands. This would include such activities as coordinating public events and providing information for the news media, as well as personal business like ordering a pizza over a phone patch.

Haller stressed that this new "third type" of amateur communications (the first two being emergency communications and "all other" permitted communications) would be on a secondary usage basis, utilizing "unused Amateur Service frequencies."

This proposal scares me, and it ought to frighten you, too.

By accepting Haller's premise, we are agreeing with him that there is an excess of "unused Amateur Service frequencies." Do you really want to stand up in front of the FCC and say, "We have plenty of unused frequencies, and I'd sure like to help out my local TV station by providing a free business band."? You and I both know that once you allow use of amateur frequencies for business purposes, it is only a matter of time before those frequencies become full-time business frequencies. As soon as you make the amateur service a business service, you can kiss it good-bye. . . and this is exactly what Haller is trying to sneak by us.

The problem with a suggestion like this is that it SOUNDS great. To be sure, there are some communications services that currently fall under the gray area of "business" that might benefit both amateur radio and the recipients of those services. A club offering communications services to local non-profit groups (which hams have been doing for decades, anyway) would be a great PR tool for amateur radio. But ordering a pizza over a phone patch? Is that what amateur radio is all about? Don't be fooled by phrases like "secondary use" or "utilize unused Amateur Service frequencies." This is a smoke screen, set up to hide the fact that business interests in this country desperately want our spectrum. Every scenario of a business use suggested by Haller already has a radio service that can take care of it. The only thing that Haller's suggestion will do is allow businesses to get free communications services, with the amateur band equipment costing thousands less than comparable business band equipment.

Now that the subject has been raised, it is inevitable that we will have some sort of change to the "no business" rule. I suggest that we all take a very hard and long look at whatever is proposed. I urge you to send a very definite message to the FCC. Tell them, especially Private Radio Bureau Chief Ralph Haller, that you see right through this charade. Tell them that you do not believe there is such a thing as "unused Amateur Service frequencies." Tell them that the Amateur Radio Service must keep itself clear of any association with business communications.

If the proposed changes are in the interest and for the benefit of amateur radio. . . fine. But let them know that we are watching their every move to see exactly what is going to come out of all this.

You might want to mention that you are also well aware of PR Docket 91-170. Oh, you mean you don't know about PR 91-170? Please, allow me to enlighten you. PR 91-170 is a move, initiated by Mr. Haller's group, which could revise the land/mobile frequency spectrum in order to make room for new and developing technologies. How coincidental that Haller now suggests that perhaps business communications should be allowed on the amateur bands. Hmmm. . . do you think the two ideas could be somehow connected? Let's see. . . "take some of the frequencies away from land/mobile users to make room for commercial experimentation, and at the same time we can start suggesting that there is an abundance of 'unused Amateur Service frequencies'. . . and wouldn't it be grand if we could make those dumb hams think we were doing them a favor by allowing them to order pizza over an autopatch, while at the same time making it possible for other business communications to get a foothold on that frequency spectrum. Those idiot hams will be so busy stuffing their faces with autopatch-ordered pizza that they won't even notice that we're stealing amateur radio's birthright out from under their tomato-sauce-stained noses."

Mr. Haller, I have never met you but I am assured by those who have that you are a reasonable and concerned individual. I'd like you to remember that we amateurs are not stupid (at least not all of us, anyway). We can see through this silk purse for what it is—the ear of a swine. We do not buy for one minute that there are an excess of "unused Amateur Service frequencies." Your promise of "secondary use" is laughable. If you're getting letters from amateurs who want this kind of "regulatory relief," tell them to buy their way onto the land/mobile service or whatever service is appropriate to their intended use. If you feel that business interests need more frequencies, give 'em some of that 200 megahertz of excess U.S. Government allocation that isn't being used. If they feel like ordering a pizza, tell them to use the phone.

Why is it that every time the FCC runs up against a small group of boneheads in amateur radio—whether it's the BARF idiots, the illegal phone-patchers, or just a bunch of hams who have forgotten what amateur radio is supposed to be all about—why is it that the FCC always tries to wash their hands of the problem by giving away a piece of amateur radio's heritage, instead of what they should be doing with our tax dollars. . . stringently enforcing the rules?

I'm sick and tired of the FCC using the "no money" excuse for not doing their jobs. Money is tight everywhere, boys. It means you have to find ways to do your job better. It doesn't mean you can simply write off an entire area of responsibility by rewriting the rules to make a problem disappear. If I did that, I'd lose my job. When a U.S. Government employee or agency does it, it is nothing short of theft. You're stealing my tax money, and it really ticks me off! If you are unable to do the jobs the American people are paying you to do. . . quit! Get the hell out of the way and let someone who knows how to run a business in there. Just stop crying to us about how little money you have and how short-staffed you are.

To those of you who have requested this kind of a rule change, I ask that you sit down for 10 minutes and ask yourself. . . is ordering a pizza over your repeater worth the raping of amateur radio? If you still think this is a good idea, drop me a line and I'll send you your reward—30 pieces of silver.

ARRL Up To Their Old Tricks

When the FCC decided it couldn't deal with licensing the Amateur Radio Service anymore (once again, abdicating their responsibility with the feeble "no money" excuse), the ARRL saw its chance to grab some more power and coyly offered to handle the licensing for them. The FCC said sure, but you can't have a monopoly. The ARRL then said, "Forget it—if we ain't the only game in town, we don't want to play."

Well, we all know how things turned out. VECs popped up all over the country, and the ARRL had to swallow its oversized pride and enter the arena as one of many VECs.

A few years ago, it was suggested that special callsign requests could be handled in much the same way. A private organization could do all the work of passing out callsigns, and the FCC wouldn't have to bother their over-worked and under-funded heads about it. Again, the geriatric gulag at the ARRL saw the chance to grab a little power. "We'll do it! We'll provide this service for amateur radio. Aren't we just the most nicest, altruistic and caring organization ever? Oh, by the way, one small, insignificant point. We want the exclusive right to do this."

The FCC told the League to stick it. They suggested that if amateurs wanted special callsign allocation, a system similar to the VEC program could be set up, but the ARRL was not going to get the exclusive. You guessed it. The ARRL backed out, making it seem like the FCC was the bad guy for not letting the nice and only-thinking-of-us-hams ARRL give you a callsign with your initials in it.

Well folks, the Geritol set at the ARRL have done it again, only this time they were a lot sneakier about it. Incorporated into the wording of HR 1674, the "Federal Communications Commission Authorization Act of 1991," was the following:

The Commission for purposes of providing specialized, radio club, and military-recreation call signs, may utilize the voluntary and uncompensated services of an incorporated association of amateur radio operators with more than 100,000 dues paying members representing all States which has a tax-exempt status under Section 501(c)(3) of the Internal Revenue Code.

Gee, what organization does that sound like to you?

Luckily, Fred Maia W5YI got wind of this behind-the-scenes power grab and contacted the House Committee overseeing the legislation. The wording was changed to let *any* amateur radio organization authorized by the FCC act as a special callsign provider.

There are two issues at work here. The first is the sneaky way the ARRL got the original wording into the bill without the amateur community ever knowing. I thought the League was "of, by, and for the radio amateur."

Of course, the ARRL often forgets that they DO NOT represent the interests of the majority of hams in this country. The majority of licensed amateurs in this country are not members of the League. This is unfortunate, because amateur radio desperately needs a national lobbying organization. What the League leadership has become is an ineffective, self-perpetuating group of old men who lost their ideals years ago. The ARRL's sole reason for being has become of, by and for the ARRL. Is it any wonder that the majority of hams in this country have chosen not to join this joke of an organization?

The biggest crime is that there is no alternative organization, and neither should there be. The ARRL is, for better or worse, THE national amateur radio organization. This blatant power grab only goes to further prove how ineffective those old men are. I only hope that by the time all the self-serving and lifeless old farts who pull the strings at the League die off, there is an Amateur Radio Service still around to protect.

(Note to League officials who take offense at the above statements: Like my mother always said when she would yell at all four of her sons for something only one or two of us were responsible for, "If you didn't do anything wrong, then I'm not talking to you." Of course, the question always remains, if you didn't do anything wrong, why do you feel that I AM talking about you?)

(Note to readers who want to write me nasty letters and accuse me of "bashing" the League: This is America, and in America we are allowed to speak out when we feel something is wrong with our government. The ARRL is setting themselves up as the "government" of U.S. amateur radio. If you would like to debate the issues

involving ineptitude and lack of leadership at the ARRL, I would be glad to hear from you. If you are one of those people who thinks we should shut up and be grateful for the benevolent wisdom of those who are mismanaging our affairs, then please, keep your letters to yourself.)

The second issue that this whole affair brings up is . . . do we really want anyone other than the FCC handing out callsigns? I don't. If we want to change the current system and allow for the issuing of expired and special callsigns, the people who are being paid to do it are the FCC. Instead of writing a rule that gives the responsibility to someone else, why doesn't the FCC write a rule that allows them to charge a fee for the extra work involved in administrating such a program (though, why checking the database to see whether or not W1DC is currently assigned should cost anything is beyond me)? Most states offer custom license plates, and they charge a premium for the privilege. So why doesn't the FCC charge 50 bucks for licensing and renewing special callsigns? This would more than pay for the few seconds of effort involved in issuing the callsign, and the rest could be put into the FCC enforcement budget. Of course, then they wouldn't have any excuses for not doing *that* part of their job.

Broadcasting

Let's start this section with a few basic assumptions. Assumption number one is that the ARRL is a broadcaster, and they make these broadcasts with the express permission and blessing of the FCC. They can even pay someone to operate the station during broadcasts. This is all fine, and well, and perfectly legal.

Let us also assume that other people who broadcast on the amateur bands, such as K1MAN's endless propaganda, and the "Newsline" show I've heard a few times, and any other group out there who puts a ham radio news show on the amateur bands are operating under the same provision of the FCC rules, and as long as they operate within the regulations, everything is hunkey-dorey and nobody gets a "Notice of Forfeiture" from our pals at the FCC.

Let us also assume, because hams all over the country have adamantly voiced this opinion to me (though I certainly would never say such a thing), that Glenn Baxter K1MAN is one of the biggest horse's behinds in amateur radio. I hate to give little people like Baxter more publicity by noticing them, but this current crop of comedy from what locals have called "Maine's #1 embarrassment" is just too funny to let by without comment.

Baxter is currently fighting a $1500 fine. He was accused of starting one of his broadcasts on top of a QSO in progress, as well as some other stuff having to do with using the amateur bands to conduct business (gee, I wonder if he and Mr. Haller are buddies) and broadcasting to non-amateurs. Baxter's defense is that the ARRL does it, so it's OK for him to do it (Baxter goes on for page after page, but this is his premise in a nutshell). As long as he publishes his broadcast schedule and announces on the frequency that his broadcast is about to start, he thinks he's following FCC regulations to the letter.

Wrong! As my mother used to say (I hate to keep bringing my mother into this, but as often happens in life, when you're faced with a jackass, mom's brand of common sense is just the ticket), "Two wrongs don't make a right." Just because the League breaks the law by not checking to see if a frequency is in use, it doesn't mean that Glenn "all mike and no speaker" Baxter can do it, too. Glenn. . . rent a brain, buddy. You're wrong, and so is the League.

I have read and reread the FCC rule book, carefully going over the regulations that permit very specific types of broadcasting. Nowhere in those regulations does it give those who broadcast the right to break any other FCC regulations, including the rules regarding control operators, good amateur practice, and not causing willful interference. Those rules are still in effect, and the League, Baxter, and anyone else who wants to broadcast amateur bulletins should keep that in mind.

Baxter also claims that ARRL 5 wpm code practice is obviously aimed at non-amateurs, so it must be OK for him to direct broadcasts to SWLs and other non-amateurs. Well Glenn, that razor's-edge mind of yours has neglected one small paragraph in Part 97. Specifically, 97.111(b)(5) which states:

In addition to one-way transmissions specifically authorized elsewhere in this Part, an amateur station may transmit the following types of one-way communications: (5) Transmissions necessary to assisting persons learning, or improving proficiency in, the international Morse code.

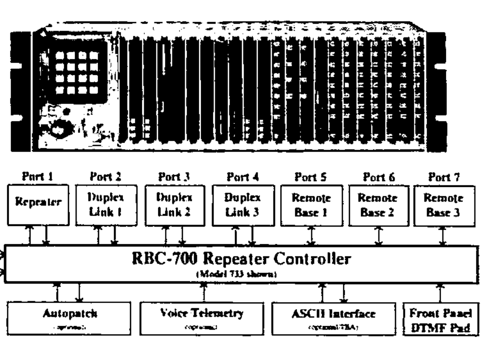
Did you read that? It specifically says "learning." The ARRL is well within the law in broadcasting 5 wpm code practice, and I support the League 100% in this endeavor. It's one of the few programs that the League has enacted that is of a direct benefit to amateur radio. So, why is Baxter bashing the League? Do you think perhaps he had a slight problem with "Reading Comprehension 101" in school?

Glenn, pick up your ego and pay the damned fine. If you're not going to play by the rules, don't play at all. If you don't like the rules there are simple ways to suggest changes, but this ego-gratifying nonsense is getting you (and amateur radio in general) nowhere. It is only making us more enemies at the FCC.

The Baxter broadcasts that I have monitored have spent more time talking about Baxter himself than any other subject. Maybe I should heed the advice of those who tell me to just ignore this. . .er. . . guy. I've been told that his incessant babble only digs his own grave, because the more he talks, the bigger an idiot he appears to be (I don't waste my time listening to enough of his broadcasts to know, but this is what I've been told time and again from hams all across the country). The biggest favor Baxter could do amateur radio, and himself, is to shut up and go away. It appears that all he's doing is serving his own ends, not those of amateur radio, and judging from the hundreds of hams I've spoken with over the past few months, the vast majority of amateur radio operators are getting tired of listening to him.

MULTIPLE REPEATER - LINK - REMOTE BASE CONTROLLER

Finally a controller that has solved control and audio interconnect problems between multiple radios. Your radio system can grow to multiple sites and stretch for hundreds of miles - and yet any radio can be fully controlled from any designated input.



The RBC-700 Repeater Controller is designed to support Repeater systems that require multiple radios connected together at a site. The RBC-700 utilizes a true 7 x 7 audio matrix switch which allows several conversations between ports at the same time. In the illustration above the 733 model is supporting a Repeater, 3 Duplexed Links to different sites, and 3 Remote Bases. Using simple commands, a user could tie the Repeater and a Remote Base to one Link, while the other Links are communicating through your site, holding separate conversations. Or, connect all of the ports together - like a big party line !!

Several models are available and are software configurable to support up to 3 Repeaters, 5 Duplexed Links, and 4 Remote Bases. A group or club can start with the basics and expand their controller anytime by simply adding boards and software. Free software upgrades for one year after delivery. Finally, a real controller for the Linked system operator !

Multiple Independent Repeater control
Up to 5 Duplexed Links
Up to 4 different Remotes
Recorded Natural Speech Telemetry
Programmable Macros
Connect / Disconnect multiple Ports
Internal Receiver Squelch processing
Easy servicing
Intergrated Autopatch
Expand at any time
Programmable Scheduler
+10v to +14v Supply
Standard 5.25" Rack Mount
Card-Cage design

BARTER 'N' BUY

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table.

The *73 Flea Market*, Barter 'n' Buy, costs you peanuts (almost)—comes to 35¢ a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

Send your ads and payment to the *Barter 'n' Buy*, Sue Colbert, Forest Road, Hancock NH 03449 *and get set for the phone calls.*

Deadline for the March classifieds is Jan. 1, 1992.

A Few Good to Fair Days

December is another of the "doldrum" months on the HF bands, but there are some real advantages as well: The bands are generally quiet, with atmospheric noise from thunderstorms at a minimum. This means that 160 and 80 meters, along with 40 and some higher bands, ought to be good for both local and DX work. The higher frequency bands from 20 through 10 meters will either close before dark, or not be open much during the day under the worst conditions.

December is the month halfway between the equinoxes, and like June, it doesn't offer much HF opportunity on the 10, 12, and 17 meter bands. However, there will be some good days during the month as well as poor ones.

Expect the poorest conditions around the first day or two of the month, and again during the week of the 11th through the 18th. The remaining days can be good to fair, as shown on the calendar and time-band-country chart. On VHF there may be some cold-front propagation along boundaries of air masses having different densities and temperatures. Sometimes a weather map can be helpful in deciding where to point the 2 meter beam. Don't expect any 6 meter openings this month.

As I write (in August), the solar flux is UP again (surprise, surprise) between 250 and 300, and the A and K indexes are low. Hey, Sol, this is supposed to be the DOWN side of your cycle! What gives? To paraphrase an old saying: "A flare every day keeps the hams away." It has been true all year. So, keep your ears open for WWV at 18 minutes past each hour for an update of conditions, and a forecast for the following 24 hours . . . plus a synopsis of the past 24 hours. Great service, that!

A partial eclipse of the moon will take place on December 21, and can be seen in Iceland and Greenland, the arctic regions, the N.W. of S. America, N. America, the Pacific Ocean, Australia except for the extreme west, Asia except for the S.W., and extreme northern Europe. 73

HIGH PERFORMANCE PRESELECTOR-PREAMP

The solution to most interference, intermod, and desense problems in repeater systems.

- 40 to 1000 Mhz tuned to your frequency
- 5 large helical resonators
- Very high rejection
- Low noise—high overload resistance
- 8 db gain—ultimate rejection >80 db
- GaAs fet option (above 200 Mhz)
- Cast aluminum enclosure
- N, BNC, and SO239 connector options

Typical rejection:
±600Khz @ 145 Mhz: 28db
±1.6 Mhz @ 220 Mhz: 40db (44db GaAs)   ±20 Mhz @ 800 Mhz: 65db
± 5 Mhz @ 450 Mhz: 50db (60db GaAs)   ±20 Mhz @ 950 Mhz: 70db

AUTOMATIC IDENTIFIERS

- Up to 8 EPROM programmed messages
- Adjustable audio, speed & interval timer
- "ID over voice inhibit"
- Low power option
- Modular design
- Message selection via binary input—TTL levels
- Size: 2.7 x 2.6 x 0.7"

Model
ID-2B

The ID-2B provides required station identification without troublesome diode programming. The "ID over voice inhibit" circuitry allows for courteous operation by not allowing an ID until the next squelch closing.

ID-2B Wired/Tested $99.95   **ID-2B-LP Low Power $109.95**
